How to Find Product Data in This Reference Manual

THIS VOLUME*

Contains Data Sheets, Selection Guides and a wealth of background information on state-of-the-art products that are suitable for new equipment design.

This volume is one member of a six-volume set of reference manuals describing and specifying Special Linear, Amplifier, Converter and Military/Aerospace products from Analog Devices, Inc.

IF YOU KNOW THE MODEL NUMBER

Turn to the product index at the back of the book and look up the model number. You will find the Section-Page location of any data sheet in this volume. You will find additional references for all other Analog Devices products currently available.

If you're looking for a form-and-function-compatible version of a product originally brought to market by some other manufacturer (second source), you may find it by adding our "AD" prefix and looking it up in the index. Or call our nearest sales office.

IF YOU DON'T KNOW THE MODEL NUMBER

Find your functional group in the list on the opposite page. Turn directly to the appropriate Section. You will find a functional Selection Tree and Selection Guide at the beginning of the Section. The Selection Tree and Selection Guide will help you find the products that are the closest to satisfying your need. Use them to compare all products in the category by salient criteria. A comprehensive Table of Contents is provided for your convenience on page 1–5 through 1–15.

IF YOU CAN'T FIND IT HERE . . . ASK

If you can't find the product you are looking for in this databook, please contact your local Analog Devices sales officer or phone our Applications Department at 617-937-1428 or 1-800-262-5643 (U.S.A. only).

See the Worldwide Sales Directory on pages 24-16 and 24-17 at the back of this volume for our sales office phone numbers.

*The fax retrieval system number shown on abridged and preliminary data sheets applies to U.S.A. and Canada only.

Contents of Other Reference Manuals

DATA CONVERTER REFERENCE MANUAL (VOLUME I)
- D/A Converters
- S/D Converters
- Communications Products
- Digital Panel Meters
- Digital Signal Processing Products
- Bus Interface & Serial I/O Products
- Application Specific ICs
- Power Supplies

DATA CONVERTER REFERENCE MANUAL (VOLUME II)
- A/D Converters
- V/F & F/V Converters
- Sample/Track-Hold Amplifiers
- Switches & Multiplexers
- Voltage References
- Data Acquisition Subsystems
- Analog I/O Ports
- Application Specific ICs
- Power Supplies

SPECIAL LINEAR REFERENCE MANUAL
- Analog Multipliers/ Dividers
- Signal Compression Components
- RMS-to-DC Converters
- Mass Storage Components
- ATE Components
- Special Function Components
- Matched Transistors
- Temperature Sensors
- Signal Conditioning Components
- Automotive Components
- Digital Signal Processing Products
- Mixed-Signal ASICs
- Power Supplies

AMPLIFIER REFERENCE MANUAL
- Operational Amplifiers
- Comparators
- Instrumentation Amplifiers
- Isolation Amplifiers
- Mixed-Signal ASICs
- Power Supplies

MILITARY/ AEROSPACE REFERENCE MANUAL
- Analog-to-Digital Converters
- Comparators
- Digital-to-Analog Converters
- Digital Signal Processing Products
- Instrumentation Amplifiers
- Multipliers/Dividers (Analog)
- Operational Amplifiers
- Sample/Track-Hold Amplifiers
- Signal Compression Components
- Switches & Multiplexers
- V/F & F/V Converters
- Voltage References

If you don't already own these volumes, you can have them FREE by getting in touch with Analog Devices or the nearest sales office or phoning 1-800-262-5643 (U.S.A. only) or 617-461-3392.

USE IN LIFE SUPPORT APPLICATIONS

Products sold by Analog Devices are not designed for use in life support equipment where malfunction of such products ca reasonably be expected to result in personal injury or death. Buyer uses or sells such products for life support application at buyer's own risk and agrees to defend, indemnify, and hold harmless Analog Devices from any and all damages, claims, suits, or expense resulting from such use.

General Information
Contents

Introduction

Analog Devices, a *Fortune* 500 Industrials company, designs, manufactures and sells worldwide sophisticated electronic components and subsystems for use in real-world signal processing. More than six hundred standard products are produced in manufacturing facilities located throughout the world. These facilities encompass all relevant technologies, including several embodiments of CMOS, BiMOS, bipolar and hybrid integrated circuits, each optimized for specific attributes—and assembled products in the form of potted modules, printed-circuit boards and instrument packages.

State-of-the-art technologies (including surface micromachining) have been utilized (and in many cases invented) to provide timely, reliable, easy-to-use advanced designs at realistic prices. Our popular IC products are available in both conventional and surface-mount packages (SOIC, LCC, PLCC), and many of our assembled products employ surface-mount technology to reduce manufacturing costs and overall size. A quarter-century of successful applications experience and continuing vertical integration ensure that these products are oriented to user needs. The ongoing application of today's state-of-the-art and the invention of tomorrow's state-of-the-art processes strengthen the leadership position of Analog Devices in standard data-acquisition and signal-processing products and make us a strong contender in high performance mixed-signal ASICs.

MAJOR PROGRESS

Since publication of the selection guides in the current set of Reference Manuals, Analog Devices has introduced more than 200 significant new products; they run the gamut from brand new product and market categories and technologies to standard products (with improvements in price, performance, or design) to augmented second source products. All of the newest products in the area of standard data converter, amplifier, and special purpose linear are included in this volume, with our latest offerings in DSP and special function products for audio, communications, and computer peripherals to be published in our forthcoming *DSP Reference Manual.*

Examples of the variety, performance, and innovation content of outstanding new linear and data converter products to be found in this volume include:

- **AD8001/AD8002** 800 MHz single and dual current feedback operational amplifiers that use only 50 mW from ± 5 volt supplies—first amplifiers from the XFCB process
- **ADXL05** second generation surface-micromachined accelerometer with ±5 g full scale and better than 1 milli-g useful resolution
- **AD7716** 22-bit quad-input sigma-delta ADC with 105 dB dynamic range at 146 Hz bandwidth on 50 mW from ±5 volt supplies
- **AD420** 16-bit complete digital-to-4-20 mA current loop driver with serial interface and 3 MHz update rate
- **AD720/AD721** RGB to NTSC/PAL encoders needing no external filters or delay lines
- **AD878** 14-bit 2.2 Msps ADC complete with SHA and reference using only 500 mW
- **AD607** complete receiver IF subsystem with mixer/AGC/RSSI from 3 volt supply
- **AD9101** 125 MHz sample-hold amplifier with 350 MHz signal bandwidth
- **OP291/OP491** rail-to-rail input/output dual and quad op amps that work down to a 2.7 volt single supply
- **AD7853/AD7858** single/octal input 12-bit 200 Msps sampling ADCs using only 5.5 mW from a 3 volt supply
- **REF190 Series** precision references with 0.5 volt dropout voltage, ±2 mV accuracy, and 45 µA supply current.

Many more could be added to this list.

DESIGN-IN REFERENCE MANUAL

This volume provides comprehensive technical data on the latest Analog Devices standard linear and data conversion products for all of the electronic industries we serve, with particular focus on the industrial, instrumentation, and military markets. This *Design-In Reference Manual* contains technical information on all of the standard linear products that we recommend for new designs. This is a companion volume and update to the series of Reference Manuals we began publishing in 1992. These manuals include the two-volume *Data Converter Reference Manual, Amplifier Reference Manual, Special Linear Reference Manual, and the Applications Reference Manual.* While this volume provides up-to-date information on our products, products which have appeared in a Reference Manual previously may have an abbreviated data sheet, so it is important to retain the entire set of Reference Manuals to have complete applications information about all of our products. If you need one of the previously printed Manuals, you can order it from our Literature Center.

In the approximately 2400 pages of this volume you will find:

- Recently released products with a complete data sheet containing all application and packaging information required to design in the product.
- Design-in products appearing in a previous Reference Manual which may have an abbreviated data sheet containing only specifications, packaging, pinout, and block diagram information, sufficient to make a design choice, but possibly not sufficient to complete a design; the full data sheets on these products are in the previously printed Reference Manuals.
- Advance technical information on upcoming new products which may prompt you to seek more up-to-date information on the product.
- Selection guides and product function trees for finding products rapidly.
- A representative list of available Analog Devices technical publications on real-world analog and digital signal processing.
- Our Worldwide Sales Directory.
- The complete Product Index to all Analog Devices products currently available or soon to be released which are covered in any of our Reference Manuals or the upcoming *DSP Reference Manual.*

The product data in this book are intended primarily for the majority of users who are concerned with new designs. For this reason, existing and available products that offer little if any unique advantage over newer products in future designs are listed in the Index, and data sheets may be available separately—but they are not published in this book.

TECHNICAL SUPPORT

Our extensive technical literature discusses the technology and applications of products for real-world signal processing. Besides tutorial material and comprehensive data sheets, including a large number in our reference manuals, we offer application notes, application guides, technical handbooks (at reasonable prices), and several free serial publications. For example, *Analog Briefings*® provides current information about products for military/avionics, and *Analog Dialogue,* our technical magazine, provides in-depth discussions of new developments in analog and digital circuit technology as applied to data acquisition, signal processing, control, and test. *DSPatch*® is a quarterly newsletter that brings its readers up-to-date applications information on our DSP products and the general field of digital signal processing. We maintain a mailing list of engineers, scientists, and technicians with a serious interest in our products. In addition to these reference manual catalogs—and general short-form selection guides—we also publish several short-form catalogs on specific product families. You will find typical publications described on pages 24–11 to 24–15 at the back of the book.

SALES AND SERVICE

Backing up our design and manufacturing capabilities and our extensive array of publications, is a network of distributors, plus sales offices and representatives throughout the United States and most of the world, staffed by experienced sales and applications engineers. Our Worldwide Sales Directory, as of the publication date, appears on pages 24–16 and 24–17 at the back of the book.

RELIABILITY

The manufacture of reliable products is a key objective at Analog Devices. The primary focus is a companywide Total Quality Management (TQM) Program. In addition, we maintain facilities that have been qualified under such standards as MIL-M-38510 (Class B and Class S) for ICs in the U.S., MIL-STD-1772 for hybrids, and ISO9000 (required by many European customers). Many of our products—both proprietary and second-source—have qualified for JAN part numbers; others are in the process. A larger number of products—including many of the newer ones just starting the JAN qualification process—are specifically characterized on Standard Military Drawings (SMDs). Most of our ICs are available in versions that comply with MIL-STD-883C Class B, and many also comply with Class S. We publish a *Military/Aerospace Reference Manual* for designers who specify ICs and hybrids for military contracts. The 1994 issue contains data on 379 product families. It also contains Mil/Aero Product Cross Reference Guides, radiation information and space qualified products information. Our newsletter *Analog Briefings* provides current information about the status of reliability at ADI.

Our PLUS program makes available standard devices (commercial and industrial grades, plastic or ceramic packaging) for *any* user with demanding application environments, at a small premium. Subjected to stringent screening, similar to MIL-STD-883 test methods, these devices are suffixed "/+" and are available from stock.

PRODUCTS NOT FOUND IN THE SELECTION GUIDES

For maximum usefulness to designers of new equipment, we have limited the contents of selection guides to standard products most likely to be used for the design of new circuits and systems with the exception of digital signal processing products. For DSP products to be included in our forthcoming *Digital Signal Processing Reference Manual,* please turn to page 24–6 at the back of this volume, Otherwise, if the model number of a product you are interested in is not in the Table of Contents, turn to page 24–4 where you will find a list of older products for which data sheets are available upon request. On page 24–7 you will find a guide to substitutions (where possible) for products no longer available.

ICs embodying combinations of functions that you need but cannot find among our standard offerings may be available to meet your specific requirements as custom designs. For more information, get in touch with Analog Devices. A complete Worldwide Sales Directory is included on pages 24–16 and 24–17.

PRICES

Accurate, up-to-date prices are an important consideration in making a choice among the many available product families. Since prices are subject to change, current price lists and/or quotations are available upon request from our sales offices and distributors.

Sampling ADCs

Model	Res Bits	Through-put Rate kSPS max	SHA BW kHz typ[1]	Reference Volt Int/Ext[2]	Bus Interface Bits[3]	Package Options[4]	Temp Ranges[5]	Comments	Page[6]
AD7821	8	1000	100	0–5 V, Ext	8, µP	E, N, P, Q, R	I, $M/_D$	CMOS, Bipolar or Unipolar Operation	2–295
AD8401	8	500	200	Int	8, µP	R	I	4-Channel, 5 V, with 8-Bit DAC	5–102
AD7820	8	500	14	0-5 V, Ext	8, µP	E, N, P, Q, R	I, $M/_D$	CMOS, 8-Bit Sampling ADC	CII 2–511
AD7569	8	400	200	Int	8, µP	E, N, P, Q, R	C, I, $M/_D$	CMOS, Complete I/O Port with DAC, ADC, SHA, Amps and Reference	2–196
AD7669	8	400	200	Int	8, µP	N, P, R	C, I, M	CMOS, Complete I/O Port with 2 DACs, ADC, SHA, Amps and Reference	2–196
AD7769	8	400	200	Ext	8, µP	N, P	C, I	CMOS, Complete 2-Channel I/O Port with Input/Output Signal Conditioning	CII 8–27
AD7824	8	400	10	0–5 V, Ext	8, µP	N, Q, R	C, I, $M/_D$	CMOS, 4-Channel, 8-Bit Sampling ADC	5–64
AD7828	8	400	10	0–5 V, Ext	8, µP	E, N, P, Q	C, I, $M/_D$	CMOS, 8-Channel, 8-Bit Sampling ADC	5–64
AD7575	8	190	50	1.23 V, Ext	8, µP	E, N, P, Q	C, I, $M/_D$	CMOS, Low Cost	2–202
AD7776	10	400	1000	2.0 V, Int/Ext	10, µP	N, R	C, I	CMOS, Single Channel Complete Sampling ADC, Single Supply, Twos Complement Output Code	5–54
AD7777	10	400	1000	2.0 V, Int/Ext	10, µP	N, R	C, I	CMOS, 4-Channel Complete ADC for Single or Simultaneous Dual Channel Sampling, Single Supply	5–54
AD7778	10	400	1000	2.0 V, Int/Ext	10, µP	S	C, I	CMOS, 8-Channel Complete ADC for Single or Simultaneous Dual Channel Sampling, Single Supply	5–54
AD872	12	10,000	70,000	+2.5 V/Int	12	D, E	C, M_D	Complete, Monolithic 12-Bit, 10 MSPS ADC	2–137
AD1671	12	1250	2000	2.5 V, Int	12	Q, P	C, I, M_D	Complete, Monolithic 12-Bit, 1.25 MSPS ADC	2–177
AD7886	12	750	1000	5 V, Ext	12, µP	N, P, Q	C, I	CMOS, 12-Bit 750 kSPS Sampling ADC	2–369
AD7891	12	600	1200	2.5, Int	8/12, Serial, µP	P, S	I, M	8-Channel High Speed, 5 V Supply	5–92
AD7892	12	600	600	2.5, Int	12, Serial, µP	N, Q, R	I, M	5 Volt Supply, Variable Range, Protected	2–375
AD678	12	200	1000	5 V, Int	8/12, µP	D, J, N	C, I, M	BiMOS, High Impedance High Bandwidth Sampling Input, 10 V Range, AC/DC Tested	2–71
AD7853	12	200	1000	Int	Serial, µP	N, R, RS	I	3 V Supply, Self-Calibrating, Low Power	2–299
AD7858	12	200	1000	Int	Serial, µP	N, R, RS	I	3 V Supply, 8 Channel, Self-Calibrating	2–299
AD1341	12	150	2500	10 V, Int	16, µP	Z	C, M/	High Speed 8/16 Channel DAS	CII 7–25
AD7893	12	140	1000	2.5 V, Ext	Serial	N, Q, R	I, M	CMOS, Single Supply Sampling ADC in 8-Pin Package	2–383
AD7896	12	125	300	Int	Serial	N, Q, R	I, M	3 Volt Serial ADC in 8-Pin Package	2–393
AD7874	12	116	500	Int (+3 V), Ext	12, µP	E, N, Q, R	C, I, $M/_D$	CMOS, Simultaneous Sampling 4-Channel ADC for ±10 V Input Signals	2–329
AD7870	12	100	500	3 V, Int	8/12/Serial, µP	N, P, Q	C, I, $M/_D$	CMOS, 100 kHz Throughput, ±3 V Input	2–317
AD7870A	12	100	500	3 V, Int	8/12/Serial, µP	N, P, Q	C, I, $M/_D$	CMOS, 100 kHz Throughput, ±3 V Input	2–317
AD7875	12	100	500	3 V, Int	8/12/Serial, µP	N, P, Q	C, I, $M/_D$	CMOS, 100 kHz Throughput, 0–5 V Input	2–317
AD7876	12	100	500	3 V, Int	8/12/Serial, µP	N, P, Q	I, M	CMOS, 100 kHz Throughput, ±10 V Input	2–317
AD7878	12	100	500	3 V, Int	12, µP	E, N, P, Q	C, I, $M/_D$	CMOS, 100 kHz Throughput, ±3 V Input, On-Chip FIFO	2–333

AD7871	**14**	**83**	**500**	**3 V, Int**	**8/14/Serial, µP**	**N, Q, P**	**C, I, M**	**CMOS, Complete Sampling ADC, ±3 V Input**	**2–323**
AD7872	**14**	**83**	**500**	**3 V, Int**	**Serial, µP**	**N, Q, R**	**C, I, M**	**CMOS, Complete, Serial Interface, 16-Pin DIP/SOIC**	**2–323**
AD1382	**16**	**500**	**2200**	**10 V, Int**	**8, µP**	**D**	**C**	**High Speed, Guaranteed Dynamic Performance**	**5–20**
AD1385	**16**	**500**	**2200**	**10 V, Int**	**8, µP**	**D**	**C, $M/_D$**	**Similar to AD1382 with Autocalibration Ability, Guaranteed Dynamic Performance**	**5–24**
AD7882	**16**	**400**	**400**	**2.5 V, Ext**	**16, µP**	**S, Q**	**I, $M/_D$**	**16-Bit Self-Calibrating ADC**	**2–341**
AD7884	**16**	**166**	**83**	**3 V, Ext**	**16, µP**	**N, Q, P**	**I**	**CMOS, Low Power (250 mW), 5.3 µs Conversion**	**2–357**
AD7885	**16**	**166**	**83**	**3 V, Ext**	**8, µP**	**N, Q, P**	**I**	**Similar to AD7884, 28-Pin Package, Byte Output**	**2–357**
AD1876	**16**	**100**	**1000**	**3–7 V, Ext**	**Serial**	**N**	**C**	**Autocalibrating, 16-Pin DIP ADC, AC Tested**	**2–193**
AD676	**16**	**100**	**1000**	**3–10 V, Ext**	**16**	**D, N**	**C, I, M**	**Autocalibrating, 28-Pin DIP, Parallel Output**	**2–43**
AD677	**16**	**100**	**1000**	**3–10 V, Ext**	**Serial**	**D, N, R**	**C, I, $M/_{DS}$**	**Autocalibrating, 16-Pin Narrow DIP, Serial Output**	**2–57**

[1]X indicates that the internal SHA bandwidth is not specified in kHz.

[2]Ext indicates external reference with the range of voltages listed where applicable. Ext (M) indicates external reference with multiplying capability. Int indicates reference is internal. A voltage value is given if the reference is pinned out.

[3]This column lists the data format for the bus with "µP" indicating microprocessor capability—e.g., for a 12-bit converter 8/12, µP indicates that the data can be formatted for an 8-bit bus or can be in parallel (12 bits) and is microprocessor compatible.

[4]Package Options: D = Hermetic DIP, Ceramic or Metal; E = Ceramic Leadless Chip Carrier; F = Ceramic Flatpack; G = Ceramic Pin Grid Array; H = Hermetic Metal Can; J = J-Leaded Ceramic Package; M = Hermetic Metal Can DIP; N = Plastic or Epoxy Sealed DIP; P = Plastic Leaded Chip Carrier; Q = Cerdip; R = Small Outline "SOIC" Package; RS = SSOP—Shrink Small Outline Package; S = Plastic Quad Flatpack; ST = Thin Quad Flatpack; T = TO-92; U = TSOP—Thin Small Outline Package; W = Nonhermetic Ceramic/Glass DIP; Y = Single-In-Line "SIP" Package; Z = Ceramic Leaded Chip Carrier.

[5]Temperature Ranges: C = Commercial, 0°C to +70°C; I = Industrial, −40°C to +85°C (Some older products −25°C to +85°C); M = Military, −55°C to +125°C. If a device has military grade offerings, the M temperature designator will be followed by: / to indicate 883B, $_J$ for JAN, $_D$ for SMD, and $_S$ for space level.

[6]CII = *Data Converter Reference Manual, Volume II*. All other entries refer to this volume.

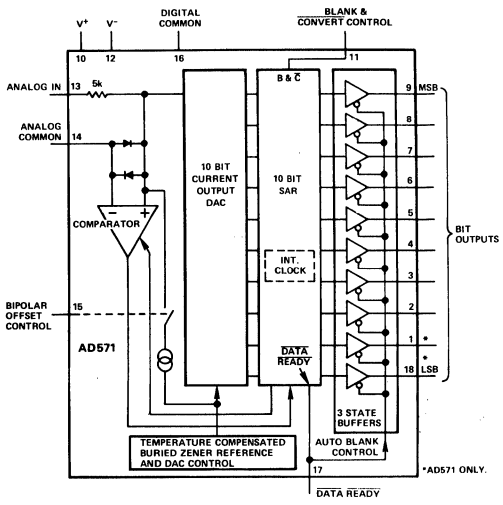
8- and 10-Bit Analog-to-Digital Converters

AD570/AD571*

FEATURES

Complete A/D Converters with Reference and Clock
AD570: 8 Bit
AD571: 10 Bit
Fast Successive Approximation Conversion – 25μs
No Missing Codes Over Temperature
Digital Multiplexing – 3 State Outputs
18-Pin Ceramic DIP
Low Cost Monolithic Construction
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTIONS

The AD570/AD571 are successive approximation A/D converters consisting of a DAC, voltage reference, clock, comparator, successive approximation register and output buffers – all fabricated on a single chip. No external components are required to perform full accuracy conversions in 25μs.

The AD570/AD571 incorporate advanced integrated circuit design and processing technologies. They employ I^2L (integrated logic) processing in the fabrication of the SAR function. Laser trimming of the high stability SiCr thin-film resistor ladder network insures high accuracy, which is maintained with a temperature compensated, subsurface Zener reference.

Operating on supplies of +5V to +15V and −15V, the AD570/AD571 will accept analog inputs of 0 to +10V, unipolar or ±5V bipolar, externally selectable. As the BLANK and $\overline{\text{CONVERT}}$ input is driven low, the three-state outputs will be open and a conversion will commence. Upon completion of the conversion, the $\overline{\text{DATA READY}}$ line will go low and the data will appear at the output. Pulling the BLANK and $\overline{\text{CONVERT}}$ high blanks the outputs and readies the device for the next conversion.

The devices are available in two versions: the "J" and "K" specified for the 0 to +70°C temperature range. The "S" guarantees the specified accuracy and no missing codes from −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. The AD571 is a complete 10-bit A/D converter. The AD570 is an 8-bit version which employs the same architecture. No external components are required to perform a conversion.
2. The AD570/AD571 are single chip devices employing advanced IC processing techniques. Thus, the user has at his disposal a truly precision component with the reliability and low cost inherent in monolithic construction.
3. The converters accept either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
4. Each device offers the specified accuracy with no missing codes over its entire operating temperature range.
5. Operation is guaranteed with −15V and +5V to +15V supplies. The devices will also operate with a −12V supply.
6. The AD570 and AD571 are available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current /883B data sheet for detailed specifications.

*Covered by Patent Nos. 3,940,760; 4,213,806; 4,136,349.

NOTES

[1]The AD570 is a selected version of the AD571 10-bit A-to-D converter. Only TTL logic inputs should be connected to Pins 1 and 18 (or no connection made) or damage may result.

[2]D = Ceramic DIP. For outline information see Package Information section.

[3]For details on grade and package offerings for SD-grade in accordance with MIL-STD-883, refer to Analog Devices Military Products databook or current /883B data sheet.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

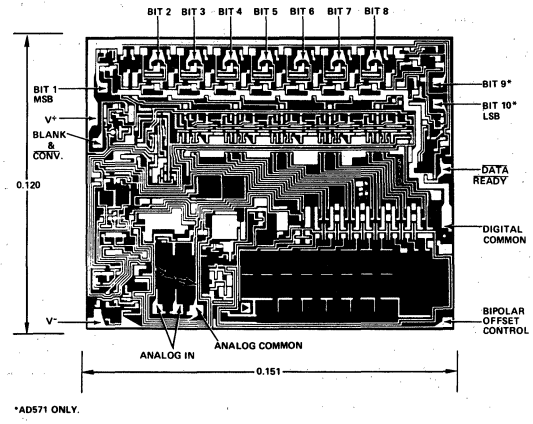
CHIP BONDING DIAGRAM



CIRCUIT DESCRIPTION

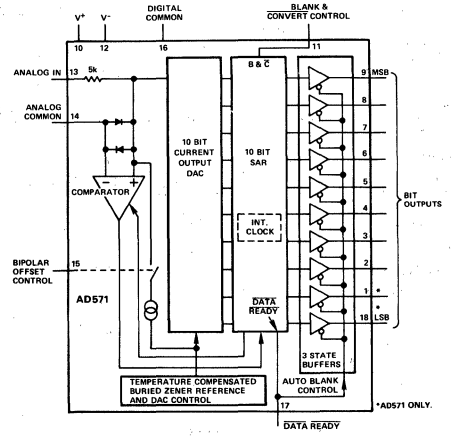
The AD571 is a complete 10-bit A/D converter which requires no external components to provide the complete successive approximation analog-to-digital conversion function. The AD570 is an 8-bit version. A functional block diagram of the AD570/AD571 is shown below. Upon receipt of the $\overline{\text{CONVERT}}$ command, the internal 10-bit (AD571) current output DAC is sequenced by the I^2L successive approximation register (SAR) from its most-significant bit (MSB) to least-significiant bit (LSB) to provide an output current which accurately balances the input signal current through the 5kΩ input resistor. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current. If the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 10-bit binary code which accurately represents the input signal to within ±1/2LSB (0.05%).

Upon completion of the sequences, the SAR sends out a $\overline{\text{DATA READY}}$ signal (active low), which also brings the three-state buffers out of their "open" state, making the bit output lines become active high or low, depending on the code in the SAR. When the BLANK and $\overline{\text{CONVERT}}$ line is brought high, the output buffers again go "open", and the SAR is prepared for another conversion cycle. Details of the timing are given further on.

The temperature compensated buried Zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The bipolar offset input controls a switch which allows a positive bipolar offset current to be injected into the summing (+) node of the comparator to offset the DAC output. The nominal 0 to +10V unipolar input range now becomes a −5V to +5V range. The 5kΩ thin-film input resistor is trimmed so that with a full-scale input signal, an input current will be generated which exactly matches the DAC output with all bits on. (The input resistor is trimmed slightly low to facilitate user trimming, as discussed on the next page.)

POWER SUPPLY SELECTION

The AD570/AD571 are designed for optimum performance using a +5V and −15V supply, for which the J and S grades are specified. AD571K will also operate with up to a +15V supply, which allows direct interface to CMOS logic.



AD570/AD571 Functional Block Diagram

CONNECTING THE AD570/AD571 FOR STANDARD OPERATION

The AD570/AD571 contain all the active components required to perform a complete A/D conversion. Thus, for most situations, all that is necessary is connection of the power supply (+5 and −15), the analog input, and the conversion start pulse. The functional pin outs are shown below.

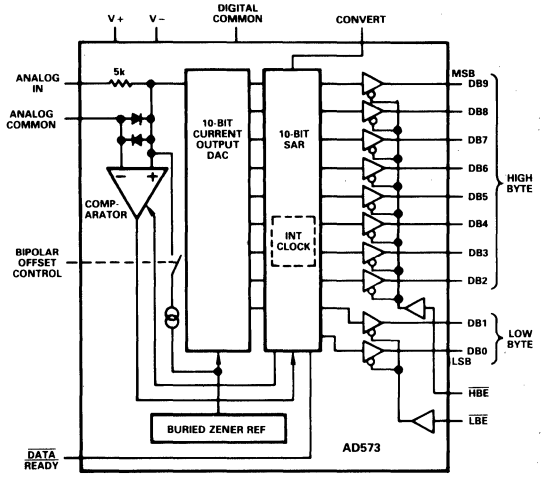
FEATURES

Complete 10-Bit A/D Converter with Reference, Clock and Comparator
Full 8- or 16-Bit Microprocessor Bus Interface
Fast Successive Approximation Conversion – 20μs typ
No Missing Codes Over Temperature
Operates on +5V and −12V to −15V Supplies
Low Cost Monolithic Construction

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD573 is a complete 10-bit successive approximation analog to digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and 3 state output buffers–all fabricated on a single chip. No external components are required to perform a full accuracy 10-bit conversion in 20μs.

The AD573 incorporates advanced integrated circuit design and processing technologies. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the high stability SiCr thin film resistor ladder network insures high accuracy, which is maintained with a temperature compensated sub-surface Zener reference.

Operating on supplies of +5V and −12V to −15V, the AD573 will accept analog inputs of 0 to +10V or −5V to +5V. The trailing edge of a positive pulse on the CONVERT line initiates the 20μs conversion cycle. $\overline{\text{DATA READY}}$ indicates completion of the conversion. $\overline{\text{HIGH BYTE ENABLE}}$ ($\overline{\text{HBE}}$) and $\overline{\text{LOW BYTE ENABLE}}$ ($\overline{\text{LBE}}$) control the 8-bit and 2-bit three state output buffers.

The AD573 is available in two versions for the 0 to +70°C temperature range, the AD573J and AD573K. The AD573S guarantees ±1LSB relative accuracy and no missing codes from −55°C to +125°C.

Three package configurations are offered. All versions are offered in a 20-pin hermetically sealed ceramic DIP. The AD573J and AD573K are also available in a 20-pin plastic DIP or 20-pin leaded chip carrier.

PRODUCT HIGHLIGHTS

1. The AD573 is a complete 10-bit A/D converter. No external components are required to perform a conversion.
2. The AD573 interfaces to many popular microprocessors without external buffers or peripheral interface adapters. The 10 bits of output data can be read as a 10-bit word or as 8- and 2-bit words.
3. The device offers true 10-bit accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD573 adapts to either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.
6. The AD573 is available in a version compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current /883B datasheet for detailed specifications.

NOTES

[1]Relative accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the zero to the full scale of the device.

[2]Full-scale calibration is guaranteed trimmable to zero with an external 50Ω potentiometer in place of the 15Ω fixed resistor. Full scale is defined as 10 volts minus 1LSB, or 9.990 volts.

[3]Defined as the resolution for which no missing codes will occur.

[4]Change from +25°C value from +25°C to T_{min} or T_{max}.

[5]The data output lines have active pull-ups to source 0.5mA. The $\overline{\text{DATA READY}}$ line is open collector with a nominal 6kΩ internal pull-up resistor.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

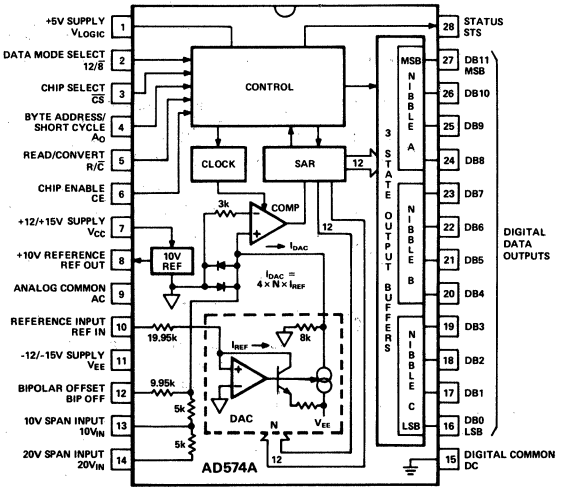
Complete 12-Bit A/D Converter

AD574A*

FEATURES

- Complete 12-Bit A/D Converter with Reference and Clock
- 8- and 16-Bit Microprocessor Bus Interface
- Guaranteed Linearity Over Temperature
  - 0 to +70°C – AD574AJ, K, L
  - −55°C to +125°C – AD574AS, T, U
- No Missing Codes Over Temperature
- 35μs Maximum Conversion Time
- Buried Zener Reference for Long-Term Stability and Low Gain T.C. 10ppm/°C max AD574AL
  12.5ppm/°C max AD574AU
- Ceramic DIP, Plastic DIP or PLCC Package
- Available in Higher Speed, Pinout-Compatible Versions (15μs AD674B, 8μs AD774B; 10μs (with SHA) AD1674)
- Available in Versions Compliant with MIL-STD-883 and JAN QPL.

BLOCK DIAGRAM AND PIN CONFIGURATION



PRODUCT DESCRIPTION

The AD574A is a complete 12-bit successive-approximation analog-to-digital converter with 3-state output buffer circuitry for direct interface to an 8- or 16-bit microprocessor bus. A high-precision voltage reference and clock are included on-chip, and the circuit guarantees full-rated performance without external circuitry or clock signals.

The AD574A design is implemented using Analog Devices' Bipolar/I^2L process, and integrates all analog and digital functions on one chip. Offset, linearity and scaling errors are minimized by active laser-trimming of thin-film resistors at the wafer stage. The voltage reference uses an implanted buried Zener for low noise and low drift. On the digital side, I^2L logic is used for the successive-approximation register, control circuitry and 3-state output buffers.

The AD574A is available in six different grades. The AD574AJ, K, and L grades are specified for operation over the 0 to +70°C temperature range. The AD574AS, T, and U are specified for the −55°C to +125°C range. All grades are available in a 28-pin hermetically-sealed ceramic DIP. Also, the J, K, and L grades are available in a 28-pin plastic DIP and PLCC, and the J and K grades are available in ceramic LCC.

The S, T, and U grades in ceramic DIP or LCC are available with optional processing to MIL-STD-883C Class B; the T and U grades are available as JAN QPL. The Analog Devices' Military Products Databook should be consulted for details on /883B testing of the AD574A.

PRODUCT HIGHLIGHTS

1. The AD574A interfaces to most 8- or 16-bit microprocessors. Multiple-mode three-state output buffers connect directly to the data bus while the read and convert commands are taken from the control bus. The 12 bits of output data can be read either as one 12-bit word or as two 8-bit bytes (one with 8 data bits, the other with 4 data bits and 4 trailing zeros).
2. The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 and 0 to +20 volts unipolar, −5 to +5 and −10 to +10 volts bipolar. Typical bipolar offset and full-scale calibration errors of ±0.1% can be trimmed to zero with one external component each.
3. The internal buried Zener reference is trimmed to 10.00 volts with 0.2% maximum error and 15ppm/°C typical T.C. The reference is available externally and can drive up to 1.5mA beyond the requirements of the reference and bipolar offset resistors.
4. AD674B (15μs) and AD774B (8μs) provide higher speed, pin compatibility; AD1674 (10μs) includes on-chip Sample-Hold Amplifier (SHA).

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD574AT(X)[2]	−55°C to +125°C	±1LSB	12 Bits	25.0
AD574AU(X)[2]	−55°C to +125°C	±1LSB	12 Bits	12.5

NOTES
[1]X = Package designator. Available packages are:
D (D-28) for all grades.
E (E-28A) for J and K grades and /883B processed S, T and U grades.
N (N-28) for J, K, and L grades.
P (P-28A)for PLCC in J, K grades.
Example: AD574AKN is K grade in plastic DIP.
[2]For details on grade and package offerings screened in accordance with MIL-STD-883, refer to Analog Devices Military Products Databook.

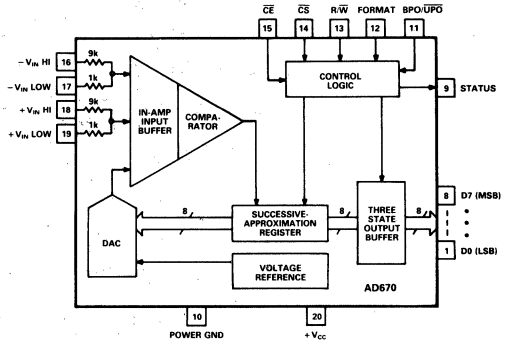
Low Cost Signal Conditioning 8-Bit ADC

AD670

FEATURES

Complete 8-Bit Signal Conditioning A/D Converter Including Instrumentation Amp and Reference
Microprocessor Bus Interface
10μs Conversion Speed
Flexible Input Stage: Instrumentation Amp Front End Provides Differential Inputs and High Common-Mode Rejection
No User Trims Required
No Missing Codes Over Temperature
Single +5V Supply Operation
Convenient Input Ranges
20-Pin DIP or Surface-Mount Package
Low Cost Monolithic Construction
MIL-STD-883B Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD670 is a complete 8-bit signal conditioning analog-to-digital converter. It consists of an instrumentation amplifier front end along with a DAC, comparator, successive approximation register (SAR), precision voltage reference, and a three-state output buffer on a single monolithic chip. No external components or user trims are required to interface, with full accuracy, an analog system to an 8-bit data bus. The AD670 will operate on the +5V system supply. The input stage provides differential inputs with excellent common-mode rejection and allows direct interface to a variety of transducers.

The device is configured with input scaling resistors to permit two input ranges: 0 to 255mV (1mV/LSB) and 0 to 2.55V (10mV/LSB). The AD670 can be configured for both unipolar and bipolar inputs over these ranges. The differential inputs and common-mode rejection of this front end are useful in applications such as conversion of transducer signals superimposed on common-mode voltages.

The AD670 incorporates advanced circuit design and proven processing technology. The successive approximation function is implemented with I^2L (integrated injection logic). Thin-film SiCr resistors provide the stability required to prevent missing codes over the entire operating temperature range while laser wafer trimming of the resistor ladder permits calibration of the device to within ±1LSB. Thus, no user trims for gain or offset are required. Conversion time of the device is 10μs.

The AD670 is available in four package types and five grades. The J and K grades are specified over 0 to +70°C and come in 20-pin plastic DIP packages or 20-terminal PLCC packages. The A and B grades (−40°C to +85°C) and the S grade (−55°C to +125°C) come in 20-pin ceramic DIP packages.

The S grade is also available with optional processing to MIL-STD-883 in 20-pin ceramic DIP or 20-terminal LCC packages. The Analog Devices Military Products Databook should be consulted for detailed specifications.

PRODUCT HIGHLIGHTS

1. The AD670 is a complete 8-bit A/D including three-state outputs and microprocessor control for direct connection to 8-bit data buses. No external components are required to perform a conversion.
2. The flexible input stage features a differential instrumentation amp input with excellent common-mode rejection. This allows direct interface to a variety of transducers without preamplification.
3. No user trims are required for 8-bit accurate performance.
4. Operation from a single +5V supply allows the AD670 to run off of the microprocessor's supply.
5. Four convenient input ranges (two unipolar and two bipolar) are available through internal scaling resistors: 0 to 255mV (1mV/LSB) and 0 to 2.55V (10mV/LSB).
6. Software control of the output mode is provided. The user can easily select unipolar or bipolar inputs and binary or 2's complement output codes.

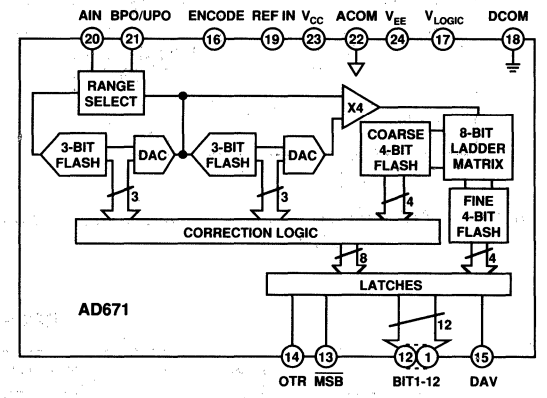
Monolithic 12-Bit 2 MHz A/D Converter

AD671

FEATURES

12-Bit Resolution
24-Pin "Skinny DIP" Package
Conversion Time: 500 ns max – AD671J/K/S-500
750 ns max – AD671J/K/S-750
Low Power: 475 mW
Unipolar (0 to +5 V, 0 to +10 V) and Bipolar Input Ranges (±5 V)
Twos Complement or Offset Binary Output Data
Out of Range Indicator
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD671 is a high speed monolithic 12-bit A/D converter offering conversion rates of up to 2 MHz (500 ns conversion time). The combination of a merged high speed bipolar/CMOS process and a novel architecture results in a combination of speed and power consumption far superior to previously available hybrid implementations. Additionally, the greater reliability of monolithic construction offers improved system reliability and lower costs than hybrid designs.

The AD671 uses a subranging flash conversion technique, with digital error correction for possible errors introduced in the first part of the conversion cycle. An on-chip timing generator provides strobe pulses for each of the four internal flash cycles and assures adequate settling time for the interflash residue amplifier. A single ENCODE pulse is used to control the converter.

The performance of the AD671 is made possible by using high speed, low noise bipolar circuitry in the linear sections and low power CMOS for the logic sections. Analog Devices' ABCMOS-1 process provides both high speed bipolar and 2-micron CMOS devices on a single chip. Laser trimmed thin-film resistors are used to provide accuracy and temperature stability.

The AD671 is available in two conversion speeds and performance grades. The AD671J and K grades are specified for operation over the 0 to +70°C temperature range. The AD671S grades are specified for operation over the −55°C to +125°C temperature range. All grades are available in a 0.300 inch wide 24-pin ceramic DIP. The J and K grades are also available in a 24-pin plastic DIP.

PRODUCT HIGHLIGHTS

1. The AD671 offers a single chip 2 MHz analog-to-digital conversion function in a space saving 24-pin DIP.
2. Input signal ranges are 0 to +5 V and 0 to +10 V unipolar, and −5 V to +5 V bipolar, selected by pin strapping. Input resistance is 1.5 kΩ. Power supplies are +5 V and −5 V, and typical power consumption is less than 500 mW.
3. The external +5 V reference can be chosen to suit the dc accuracy and temperature drift requirements of the application.
4. Output data is available in unipolar, bipolar offset or bipolar twos complement binary format.
5. An OUT OF RANGE output bit indicates when the input signal is beyond the AD671's input range.
6. The AD671 is available in versions compliant with the MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD671/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]For details on grade and package offerings screened in accordance with MIL-STD-883, refer to the Analog Devices Military Products Databook or current AD671/883 data sheet.
[2]D = Ceramic DIP. For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ANALOG DEVICES

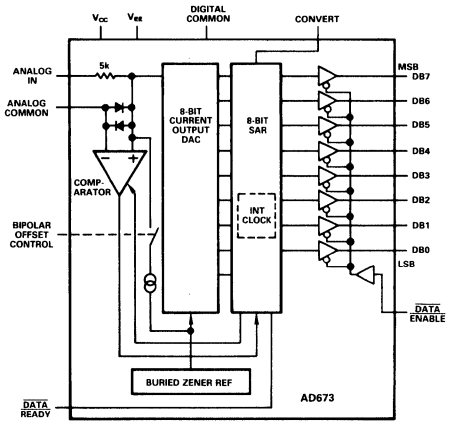
8-Bit A/D Converter

AD673*

FEATURES

Complete 8-Bit A/D Converter with Reference, Clock and Comparator
30μs Maximum Conversion Time
Full 8- or 16-Bit Microprocessor Bus Interface
Unipolar and Bipolar Inputs
No Missing Codes Over Temperature
Operates on +5V and −12V to −15V Supplies
MIL-STD-883 Compliant Version Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD673 is a complete 8-bit successive approximation analog-to-digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and 3 state output buffers–all fabricated on a single chip. No external components are required to perform a full accuracy 8-bit conversion in 20μs.

The AD673 incorporates advanced integrated circuit design and processing technologies. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the high stability SiCr thin film resistor ladder network insures high accuracy, which is maintained with a temperature compensated sub-surface Zener reference.

Operating on supplies of +5V and −12V to −15V, the AD673 will accept analog inputs of 0 to +10V or −5V to +5V. The trailing edge of a positive pulse on the CONVERT line initiates the 20μs conversion cycle. DATA READY indicates completion of the conversion.

The AD673 is available in two versions. The AD673J as specified over the 0 to +70°C temperature range and the AD673S guarantees ±½LSB relative accuracy and no missing codes from −55°C to +125°C.

Two package configurations are offered. All versions are also offered in a 20-pin hermetically sealed ceramic DIP. The AD673J is also available in a 20-pin plastic DIP.

***Protected by U.S. Patent Nos. 3,940,760; 4,213,806; 4,136,349; 4,400,689; and 4,400,690**

PRODUCT HIGHLIGHTS

1. The AD673 is a complete 8-bit A/D converter. No external components are required to perform a conversion.
2. The AD673 interfaces to many popular microprocessors without external buffers or peripheral interface adapters.
3. The device offers true 8-bit accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD673 adapts to either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.
6. The AD673 is available in a version compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD673/883B data sheet for detailed specifications.

NOTES

[1]Relative accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the zero to the full scale of the device.

[2]Full scale calibration is guaranteed trimmable to zero with an external 200Ω potentiometer in place of the 15Ω fixed resistor.
Full scale is defined as 10 volts minus 1LSB, or 9.961 volts.

[3]Defined as the resolution for which no missing codes will occur.

[4]The data output lines have active pull-ups to source 0.5mA. The $\overline{\text{DATA READY}}$ line is open collector with a nominal 6kΩ internal pull-up resistor.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

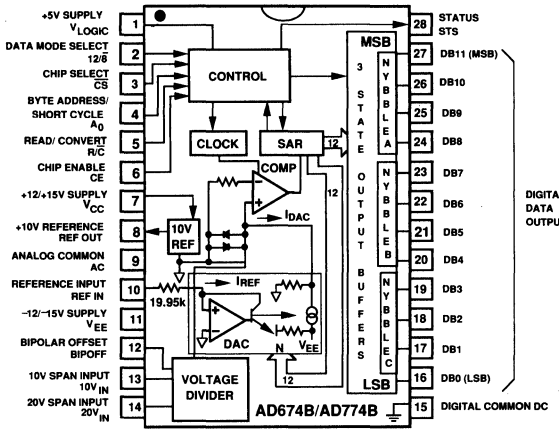
Commercial, Industrial and Military Temperature Range Grades
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD674B and AD774B are complete 12-bit successive-approximation analog-to-digital converters with three-state output buffer circuitry for direct interface to 8- and 16-bit microprocessor busses. A high precision voltage reference and clock are included on chip, and the circuit requires only power supplies and control signals for operation.

The AD674B and AD774B are pin compatible with the industry-standard AD574A, but offer faster conversion time and bus-access speed than the AD574A and lower power consumption. The AD674B converts in 15 μs (maximum) and the AD774B converts in 8 μs (maximum).

The monolithic design is implemented using Analog Devices' BiMOS II process allowing high performance bipolar analog circuitry to be combined on the same die with digital CMOS logic. Offset, linearity and scaling errors are minimized by active laser-trimming of thin-film resistors.

Five different grades are available. The J and K grades are specified for operation over the 0°C to +70°C temperature range. The A and B grades are specified from −40°C to +85°C, the T grade is specified from −55°C to +125°C. The J and K grades are available in a 28-pin plastic DIP or 28-lead SOIC. All other grades are available in a 28-pin hermetically sealed ceramic DIP.

***Protected by U.S. Patent Nos. 4,250,445; 4,808,908; RE30586.**

PRODUCT HIGHLIGHTS

1. Industry Standard Pinout: The AD674B and AD774B utilize the pinout established by the industry standard AD574A.
2. Analog Operation: The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 V and 0 to +20 V unipolar; −5 V to +5 V and −10 V to +10 V bipolar. The AD674B and AD774B operate on +5 V and ±12 V or ±15 V power supplies.
3. Flexible Digital Interface: On-chip multiple-mode three-state output buffers and interface logic allow direct connection to most microprocessors. The 12 bits of output data can be read either as one 12-bit word or as two 8-bit bytes (one with 8 data bits, the other with 4 data bits and 4 trailing zeros).
4. The internal reference is trimmed to 10.00 volts with 1% maximum error and 10 ppm/°C typical temperature coefficient. The reference is available externally and can drive up to 2.0 mA beyond the requirements of the converter and bipolar offset resistors.
5. The AD674B and AD774B are available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD674B/AD774B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

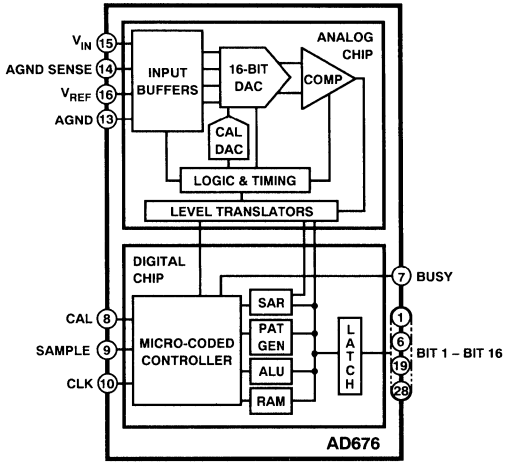
16 Bits No Missing Codes
±1 LSB INL
−97 dB THD
90 dB S/(N+D)
1 MHz Full Power Bandwidth

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD676 is a multipurpose 16-bit parallel output analog-to-digital converter which utilizes a switched-capacitor/charge redistribution architecture to achieve a 100 kSPS conversion rate (10 μs total conversion time). Overall performance is optimized by digitally correcting internal nonlinearities through on-chip autocalibration.

The AD676 circuitry is segmented onto two monolithic chips—a digital control chip fabricated on Analog Devices DSP CMOS process and an analog ADC chip fabricated on our BiMOS II process. Both chips are contained in a single package.

The AD676 is specified for ac (or "dynamic") parameters such as S/(N+D) Ratio, THD and IMD which are important in signal processing applications. In addition, dc parameters are specified which are important in measurement applications.

The AD676 operates from +5 V and ±12 V supplies and typically consumes 360 mW during conversion. The digital supply (V_{DD}) is separated from the analog supplies (V_{CC}, V_{EE}) for reduced digital crosstalk. An analog ground sense is provided for the analog input. Separate analog and digital grounds are also provided.

The AD676 is available in a 28-pin plastic DIP or 28-pin side-brazed ceramic package. A serial-output version, the AD677, is available in a 16-pin 300 mil wide ceramic or plastic package.

ABSOLUTE MAXIMUM RATINGS*

V_{CC} to V_{EE} . . . . . −0.3 V to +26.4 V
V_{DD} to DGND . . . . . −0.3 V to +7 V
V_{CC} to AGND . . . . . −0.3 V to +18 V
V_{EE} to AGND . . . . . −18 V to +0.3 V
AGND to DGND . . . . . ±0.3 V
Digital Inputs to DGND . . . . . 0 to +5.5 V
Analog Inputs, V_{REF} to AGND
. . . . . (V_{CC} + 0.3 V) to (V_{EE} − 0.3 V)
Soldering . . . . . +300°C, 10 sec
Storage Temperature . . . . . −65°C to +150°C

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

The AD676 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD676 has been classified as a Category 1 Device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment, and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam discharged to the destination socket before devices are removed. For further information on ESD precaution, refer to Analog Devices' *ESD Prevention Manual*.

PIN DESCRIPTION

Pin	Name	Type	Description
1–6	BIT 11–BIT 16	DO	BIT 11–BIT 16 represent the six LSBs of data.
7	BUSY	DO	Status Line for Converter. Active HIGH, indicating a conversion or calibration in progress. BUSY should be buffered when capacitively loaded.
8	CAL	DI	Calibration Control Pin (Asynchronous).
9	SAMPLE	DI	V_{IN} Acquisition Control Pin. Active HIGH. During conversion, SAMPLE controls the state of the internal sample-hold amplifier and the falling edge initiates conversion (see "Conversion Control" paragraph). During calibration, SAMPLE should be held LOW. If HIGH during calibration, diagnostic information will appear on the two LSBs (Pins 5 and 6).
10	CLK	DI	Master Clock Input. The AD676 requires 17 clock cycles to execute a conversion.
11	DGND	P	Digital Ground.
12	V_{CC}	P	+12 V Analog Supply Voltage.
13	AGND	P/AI	Analog Ground.
14	AGND SENSE	AI	Analog Ground Sense.
15	V_{IN}	AI	Analog Input Voltage.
16	V_{REF}	AI	External Voltage Reference Input.
17	V_{EE}	P	−12 V Analog Supply Voltage. Note: the lid of the ceramic package is internally connected to V_{EE}.
18	V_{DD}	P	+5 V Logic Supply Voltage.
19–28	BIT 1–BIT 10	DO	BIT 1–BIT 10 represent the ten MSB of data.

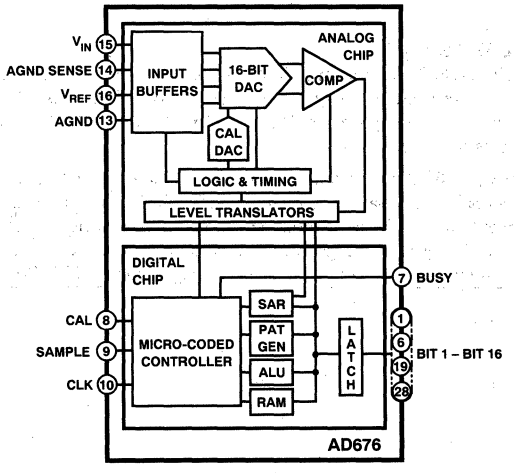
Package Pinout



Functional Block Diagram

NYQUIST FREQUENCY
An implication of the Nyquist sampling theorem, the "Nyquist frequency" of a converter is that input frequency which is one half the sampling frequency of the converter.

TOTAL HARMONIC DISTORTION
Total harmonic distortion (THD) is the ratio of the rms sum of the harmonic components to the rms value of a full-scale input signal and is expressed in percent (%) or decibels (dB). For input signals or harmonics that are above the Nyquist frequency, the aliased components are used.

SIGNAL-TO-NOISE PLUS DISTORTION RATIO
Signal-to-noise plus distortion is defined to be the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

GAIN ERROR
The last transition should occur at an analog value 1.5 LSB below the nominal full scale (4.99977 volts for a ±5 V range). The gain error is the deviation of the actual difference between the first and last code transition from the ideal difference between the first and last code transition.

BIPOLAR ZERO ERROR
Bipolar zero error is the difference between the ideal midscale input voltage (0 V) and the actual voltage producing the midscale output code.

DIFFERENTIAL NONLINEARITY (DNL)
In an ideal ADC, code transitions are one LSB apart. Differential nonlinearity is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

INTEGRAL NONLINEARITY (INL)
The ideal transfer function for an ADC is a straight line bisecting the center of each code drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the most negative code transition. "Full scale" is defined as a level 1.5 LSB beyond the most positive code transition. Integral nonlinearity is the worst-case deviation of a code center average from the straight line.

BANDWIDTH
The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb), and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude, and the peak value of their sum is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

APERTURE DELAY
Aperture delay is the time required after SAMPLE pin is taken LOW for the internal sample-hold of the AD676 to open, thus holding the value of V_{IN}.

APERTURE JITTER
Aperture jitter is the variation in the aperture delay from sample to sample.

POWER SUPPLY REJECTION
DC variations in the power supply voltage will affect the overall transfer function of the ADC, resulting in zero error and gain error changes. Power supply rejection is the maximum change in either the bipolar zero error or gain error value. Additionally, there is another power supply variation to consider. AC ripple on the power supplies can couple noise into the ADC, resulting in degradation of dynamic performance. This is displayed in Figure 16.

INPUT SETTLING TIME
Settling time is a function of the SHA's ability to track fast slewing signals. This is specified as the maximum time required in track mode after a full-scale step input to guarantee rated conversion accuracy.

FUNCTIONAL DESCRIPTION

The AD676 is a multipurpose 16-bit analog-to-digital converter and includes circuitry which performs an input sample/hold function, ground sense, and autocalibration. These functions are segmented onto two monolithic chips—an analog signal processor and a digital controller. Both chips are contained within the AD676 package.

The AD676 employs a successive-approximation technique to determine the value of the analog input voltage. However, instead of the traditional laser-trimmed resistor-ladder approach, this device uses a capacitor-array, charge redistribution technique. Binary-weighted capacitors subdivide the input sample to perform the actual analog-to-digital conversion. The capacitor array eliminates variation in the linearity of the device due to temperature-induced mismatches of resistor values. Since a capacitor array is used to perform the data conversions, the sample/hold function is included without the need for additional external circuitry.

Initial errors in capacitor matching are eliminated by an autocalibration circuit within the AD676. This circuit employs an on-chip microcontroller and a calibration DAC to measure and compensate capacitor mismatch errors. As each error is determined, its value is stored in on-chip memory (RAM). Subsequent conversions use these RAM values to improve conversion accuracy. The autocalibration routine may be invoked at any time. Autocalibration insures high performance while eliminating the need for any user adjustments and is described in detail below.

The microcontroller controls all of the various functions within the AD676. These include the actual successive approximation algorithm, the autocalibration routine, the sample/hold operation, and the internal output data latch.

AUTOCALIBRATION

The AD676 achieves rated performance without the need for user trims or adjustments. This is accomplished through the use of on-chip autocalibration.

In the autocalibration sequence, sample/hold offset is nulled by internally connecting the input circuit to the ground sense circuit. The resulting offset voltage is measured and stored in RAM for later use. Next, the capacitor representing the most significant bit (MSB) is charged to the reference voltage. This charge is then transferred to a capacitor of equal size (composed of the sum of the remaining lower weight bits). The difference in the voltage that results and the reference voltage represents the amount of capacitor mismatch. A calibration digital-to-analog converter (DAC) adds an appropriate value of error correction voltage to cancel this mismatch. This correction factor is also stored in RAM. This process is repeated for each of the capacitors representing the remaining top eight bits. The accumulated values in RAM are then used during subsequent conversions to adjust conversion results accordingly.

As shown in Figure 1, when CAL is taken HIGH the AD676 internal circuitry is reset, the BUSY pin is driven HIGH, and the ADC prepares for calibration. This is an asynchronous hardware reset and will interrupt any conversion or calibration currently in progress. Actual calibration begins when CAL is taken LOW and completes in 85,530 clock cycles, indicated by BUSY going LOW. During calibration, it is preferable for SAMPLE to be held LOW. If SAMPLE is HIGH, diagnostic data will appear on Pins 5 and 6. This data is of no value to the user.

The AD676 requires one clock cycle after BUSY goes LOW to complete the calibration cycle. If this clock cycle is not provided, it will be taken from the first conversion, likely resulting in first conversion error.

In most applications, it is sufficient to calibrate the AD676 only upon power-up, in which case care should be taken that the power supplies and voltage reference have stabilized first. If not calibrated, the AD676 accuracy may be as low as 10 bits.

CONVERSION CONTROL

The AD676 is controlled by two signals: SAMPLE and CLK, as shown in Figures 2a and 2b. It is assumed that the part has been calibrated and the digital I/O pins have the levels shown at the start of the timing diagram.

A conversion consists of an input acquisition followed by 17 clock pulses which execute the 16-bit internal successive approximation routine. The analog input is acquired by taking the SAMPLE line HIGH for a minimum sampling time of t_S. The actual sample taken is the voltage present on V_{IN} one aperture delay after the SAMPLE line is brought LOW, assuming the previous conversion has completed (signified by BUSY going LOW). Care should be taken to ensure that this negative edge is well defined and jitter free in ac applications to reduce the uncertainty (noise) in signal acquisition. With SAMPLE going LOW, the AD676 commits itself to the conversion—the input at V_{IN} is disconnected from the internal capacitor array, BUSY goes HIGH, and the SAMPLE input will be ignored until the conversion is completed (when BUSY goes LOW). SAMPLE must be held LOW for a minimum period of time t_{SL}. A period of time t_{SC} after bringing SAMPLE LOW, the 17 CLK cycles are applied; CLK pulses that start before this period of time are ignored. BUSY goes HIGH t_{SB} after SAMPLE goes LOW, signifying that a conversion is in process, and remains HIGH until the conversion is completed. BUSY goes LOW during the 17th CLK cycle at the point where the data outputs have changed and are valid. The AD676 will ignore CLK after BUSY has gone LOW and the output data will remain constant until a new conversion is completed. The data can, therefore, be read any time after BUSY goes LOW and before the 17th CLK of the next conversion (see Figures 2a and 2b). The section on Microprocessor Interfacing discusses how the AD676 can be interfaced to a 16-bit databus.

Typically BUSY would be used to latch the AD676 output data into buffers or to interrupt microprocessors or DSPs. It is recommended that the capacitive load on BUSY be minimized by driving no more than a single logic input. Higher capacitive loads such as cables or multiple gates may degrade conversion quality unless BUSY is buffered.

CONTINUOUS CONVERSION

For maximum throughput rate, the AD676 can be operated in a continuous convert mode (see Figure 2b). This is accomplished by utilizing the fact that SAMPLE will no longer be ignored after BUSY goes LOW, so an acquisition may be initiated even

during the HIGH time of the 17th CLK pulse for maximum throughput rate while enabling full settling of the sample/hold circuitry. If SAMPLE is already HIGH when BUSY goes LOW at the end of a conversion, then an acquisition is immediately initiated and t_S and t_C start from that time. Data from the previous conversion may be latched up to t_{SD} before BUSY goes LOW or t_{OD} after the rising edge of the 17th clock pulse. However, it is preferred that latching occur on or after the falling edge of BUSY.

Care must be taken to adhere to the minimum/maximum timing requirements in order to preserve conversion accuracy.

GENERAL CONVERSION GUIDELINES

During signal acquisition and conversion, care should be taken with the logic inputs to avoid digital feedthrough noise. It is possible to run CLK continuously, even during the sample period. However, CLK edges during the sampling period, and especially when SAMPLE goes LOW, may inject noise into the sampling process. The AD676 is tested with no CLK cycles during the sampling period. The BUSY signal can be used to prevent the clock from running during acquisition, as illustrated in Figure 3. In this circuit BUSY is used to reset the circuitry which divides the system clock down to provide the AD676 CLK. This serves to interrupt the clock until after the input signal has been acquired, which has occurred when BUSY goes HIGH. When the conversion is completed and BUSY goes LOW, the circuit in Figure 3 truncates the 17th CLK pulse width which is tolerable because only its rising edge is critical.

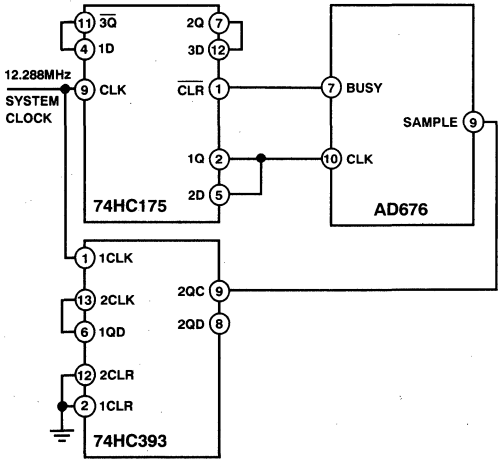


Figure 3.

Figure 3 also illustrates the use of a counter (74HC393) to derive the AD676 SAMPLE command from the system clock when a continuous convert mode is desirable. Pin 9 (2QC) provides a 96 kHz sample rate for the AD676 when used with a 12.288 MHz system clock. Alternately, Pin 8 (2QD) could be used for a 48 kHz rate.

If a continuous clock is used, then the user must avoid CLK edges at the instant of disconnecting V_{IN} which occurs at the falling edge of SAMPLE (see t_{SC} specification). The duty cycle of CLK may vary, but both the HIGH (t_{CH}) and LOW (t_{CL}) phases must conform to those shown in the timing specifications. The internal comparator makes its decisions on the rising edge of CLK. To avoid a negative edge transition disturbing the comparator's settling, t_{CL} should be at least half the value of t_{CLK}. To also avoid transitions disturbing the internal comparator's settling, it is not recommended that the SAMPLE pin change state toward the end of a CLK cycle.

During a conversion, internal dc error terms such as comparator voltage offset are sampled, stored on internal capacitors and used to correct for their corresponding errors when needed. Because these voltages are stored on capacitors, they are subject to leakage decay and so require refreshing. For this reason there is a maximum conversion time t_C (1000 μs). From the time SAMPLE goes HIGH to the completion of the 17th CLK pulse, no more than 1000 μs should elapse for specified performance. However, there is no restriction to the maximum time between conversions.

Output coding for the AD676 is twos complement, as shown in Table I. By inverting the MSB, the coding can be converted to offset binary. The AD676 is designed to limit output coding in the event of out-of-range inputs.

Table 1. Output Coding

−Full Scale	100 . . . 00
<−Full Scale	100 . . . 00

POWER SUPPLIES AND DECOUPLING

The AD676 has three power supply input pins. V_{CC} and V_{EE} provide the supply voltages to operate the analog portions of the AD676 including the ADC and sample-hold amplifier (SHA). V_{DD} provides the supply voltage which operates the digital portions of the AD676 including the data output buffers and the autocalibration controller.

As with most high performance linear circuits, changes in the power supplies can produce undesired changes in the performance of the circuit. Optimally, well regulated power supplies with less than 1% ripple should be selected. The ac output impedance of a power supply is a complex function of frequency, and in general will increase with frequency. In other words, high frequency switching such as that encountered with digital circuitry requires fast transient currents which most power supplies cannot adequately provide. This results in voltage spikes on the supplies. If these spikes exceed the ±5% tolerance of the ±12 V supplies or the ±10% limits of the +5 V supply, ADC performance will degrade. Additionally, spikes at frequencies higher than 100 kHz will also degrade performance. To compensate for the finite ac output impedance of the supplies, it is necessary to store "reserves" of charge in bypass capacitors. These capacitors can effectively lower the ac impedance presented to the AD676 power inputs which in turn will significantly reduce the magnitude of the voltage spikes. For

bypassing to be effective, certain guidelines should be followed. Decoupling capacitors, typically 0.1 μF, should be placed as closely as possible to each power supply pin of the AD676. It is essential that these capacitors be placed physically close to the IC to minimize the inductance of the PCB trace between the capacitor and the supply pin. The logic supply (V_{DD}) should be decoupled to digital common and the analog supplies (V_{CC} and V_{EE}) to analog common. The reference input is also considered as a power supply pin in this regard and the same decoupling procedures apply. These points are displayed in Figure 4.

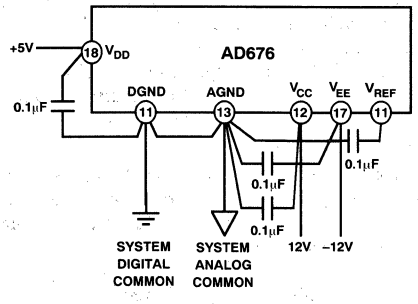

Figure 4. Grounding and Decoupling the AD676

Additionally, it is beneficial to have large capacitors (>47 μF) located at the point where the power connects to the PCB with 10 μF capacitors located in the vicinity of the ADC to further reduce low frequency ripple. In systems that will be subjected to particularly harsh environmental noise, additional decoupling may be necessary. RC-filtering on each power supply combined with dedicated voltage regulation can substantially decrease power supply ripple effects (this is further detailed in Figure 7).

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. A 1.22 mA current through a 0.5 Ω trace will develop a voltage drop of 0.6 mV, which is 4 LSBs at the 16-bit level for a 10 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals.

Analog and digital signals should not share a common return path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point at the AD676 to minimize interference between analog and digital circuitry. Analog signals should be routed as far as possible from digital signals and should cross them, if at all, only at right angles. A solid analog ground plane around the AD676 will isolate it from large switching ground currents. For these reasons, the use of wire wrap circuit construction will not provide adequate performance; careful printed circuit board construction is preferred.

GROUNDING

The AD676 has three grounding pins, designated ANALOG GROUND (AGND), DIGITAL GROUND (DGND) and ANALOG GROUND SENSE (AGND SENSE). The analog ground pin is the "high quality" ground reference point for the device, and should be connected to the analog common point in the system.

AGND SENSE is intended to be connected to the input signal ground reference point. This allows for slight differences in level between the analog ground point in the system and the input signal ground point. However no more than 100 mV is recommended between the AGND and the AGND SENSE pins for specified performance.

Using AGND SENSE to remotely sense the ground potential of the signal source can be useful if the signal has to be carried some distance to the A/D converter. Since all IC ground currents have to return to the power supply and no ground leads are free from resistance and inductance, there are always some voltage differences from one ground point in a system to another.

Over distance this voltage difference can easily amount to several LSBs (in a 10 V input span, 16-bit system each LSB is about 0.15 mV). This would directly corrupt the A/D input signal if the A/D measures its input with respect to power ground (AGND) as shown in Figure 5a. To solve this problem the AD676 offers an AGND SENSE pin. Figure 5b shows how the AGND SENSE can be used to eliminate the problem in Figure 5a. Figure 5b also shows how the signal wires should be shielded in a noisy environment to avoid capacitive coupling. If inductive (magnetic) coupling is expected to be dominant such as where motors are present, twisted-pair wires should be used instead.

The digital ground pin is the reference point for all of the digital signals that operate the AD676. This pin should be connected to the digital common point in the system. As Figure 4 illustrated, the analog and digital grounds should be connected together at one point in the system, preferably at the AD676.

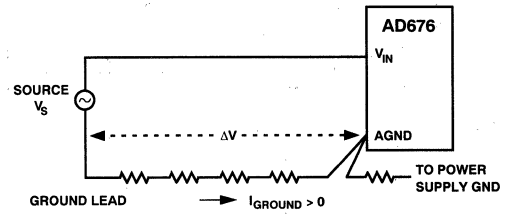

Figure 5a. Input to the A/D Is Corrupted by IR Drop in Ground Leads: $V_{IN} = V_S + \Delta V$.

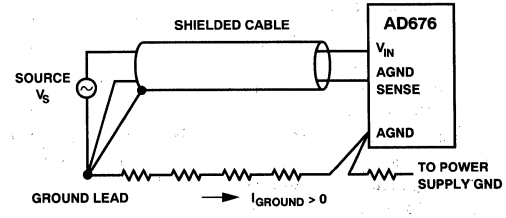

Figure 5b. AGND SENSE Eliminates the Problem in Figure 5a.

VOLTAGE REFERENCE

The AD676 requires the use of an external voltage reference. The input voltage range is determined by the value of the reference voltage; in general, a reference voltage of n volts allows an input range of ±n volts. The AD676 is specified for both 10 V and 5.0 V references. A 10 V reference will typically require support circuitry operated from ±15 V supplies; a 5.0 V reference may be used with ±12 V supplies. Signal-to-noise performance is increased proportionately with input signal range. In the presence of a fixed amount of system noise, increasing the LSB size (which results from increasing the reference voltage) will increase the effective S/(N+D) performance. Figure 12 illustrates S/(N+D) as a function of reference voltage. In contrast, INL will be optimal at lower reference voltage values (such as 5 V) due to capacitor nonlinearity at higher voltage values.

During a conversion, the switched capacitor array of the AD676 presents a dynamically changing current load at the voltage reference as the successive-approximation algorithm cycles through various choices of capacitor weighting. (See the following section "Analog Input" for a detailed discussion of the V_{REF} input characteristics.) The output impedance of the reference circuitry must be low so that the output voltage will remain sufficiently constant as the current drive changes. In some applications, this may require that the output of the voltage reference be buffered by an amplifier with low impedance at relatively high frequencies. In choosing a voltage reference, consideration should be made for selecting one with low noise. A capacitor connected between REF IN and AGND will reduce the demands on the reference by decreasing the magnitude of high frequency components required to be sourced by the reference.

Figures 6 and 7 represent typical design approaches.

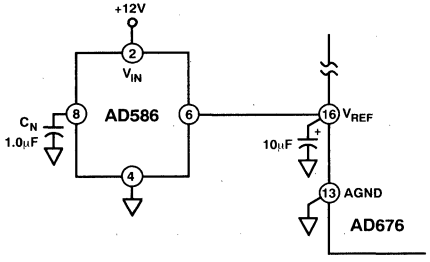

Figure 6.

Figure 6 shows a voltage reference circuit featuring the 5 V output AD586. The AD586 is a low cost reference which utilizes a buried Zener architecture to provide low noise and drift. Over the 0°C to +70°C range, the AD586L grade exhibits less than 2.25 mV output change from its initial value at +25°C. A noise-reduction capacitor, C_N, reduces the broadband noise of the AD586 output, thereby optimizing the overall performance of the AD676. It is recommended that a 10 µF to 47 µF high quality tantalum capacitor be tied between the V_{REF} input of the AD676 and ground to minimize the impedance on the reference.

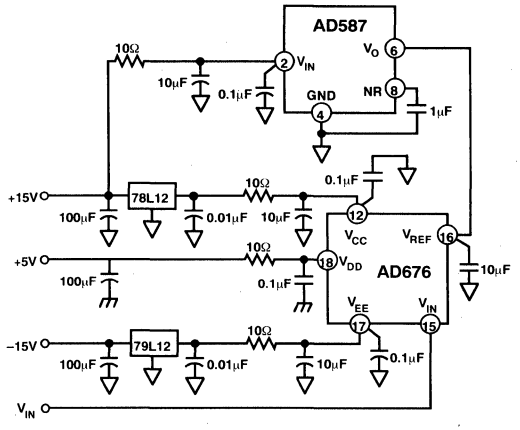

Figure 7.

Using the AD676 with ±10 V input range (V_{REF} = 10 V) typically requires ±15 V supplies to drive op amps and the voltage reference. If ±12 V is not available in the system, regulators such as 78L12 and 79L12 can be used to provide power for the AD676. This is also the recommended approach (for any input range) when the ADC system is subjected to harsh environments such as where the power supplies are noisy and where voltage spikes are present. Figure 7 shows an example of such a system based upon the 10 V AD587 reference, which provides a 300 µV LSB. Circuitry for additional protection against power supply disturbances has been shown. A 100 µF capacitor at each regulator prevents very large voltage spikes from entering the regulators. Any power line noise which the regulators cannot eliminate will be further filtered by an RC filter (10 Ω/10 µF) having a −3 dB point at 1.6 kHz. For best results the regulators should be within a few centimeters of the AD676.

ANALOG INPUT

As previously discussed, the analog input voltage range for the AD676 is $\pm V_{REF}$. For purposes of ground drop and common mode rejection, the V_{IN} and V_{REF} inputs each have their own ground. V_{REF} is referred to the local analog system ground (AGND), and V_{IN} is referred to the analog ground sense pin (AGND SENSE) which allows a remote ground sense for the input signal.

The AD676 analog inputs (V_{IN}, V_{REF} and AGND SENSE) exhibit dynamic characteristics. When a conversion cycle begins, each analog input is connected to an internal, discharged 50 pF capacitor which then charges to the voltage present at the corresponding pin. The capacitor is disconnected when SAMPLE is taken LOW, and the stored charge is used in the subsequent conversion. In order to limit the demands placed on the external source by this high initial charging current, an internal buffer amplifier is employed between the input and this capacitance for a few hundred nanoseconds. During this time the input pin exhibits typically 20 kΩ input resistance, 10 pF input capacitance and ±40 µA bias current. Next, the input is switched

directly to the now precharged capacitor and allowed to fully settle. During this time the input sees only a 50 pF capacitor. Once the sample is taken, the input is internally floated so that the external input source sees a very high input resistance and a parasitic input capacitance of typically only 2 pF. As a result, the only dominant input characteristic which must be considered is the high current steps which occur when the internal buffers are switched in and out.

In most cases, these characteristics require the use of an external op amp to drive the input of the AD676. Care should be taken with op amp selection; even with modest loading conditions, most available op amps do not meet the low distortion requirements necessary to match the performance capabilities of the AD676. Figure 8 represents a circuit, based upon the AD845, recommended for low noise, low distortion ac applications.

For applications optimized more for low bias and low offset than speed or bandwidth, the AD845 of Figure 8 may be replaced by the OP-27.

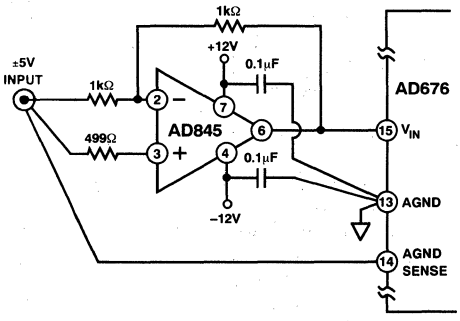

Figure 8.

AC PERFORMANCE

AC parameters, which include S/(N+D), THD, etc., reflect the AD676's effect on the spectral content of the analog input signal. Figures 12 through 16 provide information on the AD676's ac performance under a variety of conditions.

As a general rule, averaging the results from several conversions reduces the effects of noise, and therefore improves such parameters as S/(N+D). AD676 performance may be optimized by operating the device at its maximum sample rate of 100 kSPS and digitally filtering the resulting bit stream to the desired signal bandwidth. This succeeds in distributing noise over a wider frequency range, thus reducing the noise density in the frequency band of interest. This subject is discussed in the following section.

OVERSAMPLING AND NOISE FILTERING

The Nyquist rate for a converter is defined as one-half its sampling rate. This is established by the Nyquist theorem, which requires that a signal be sampled at a rate corresponding to at least twice its highest frequency component of interest in order to preserve the informational content. Oversampling is a conversion technique in which the sampling frequency is more than twice the frequency bandwidth of interest. In audio applications, the AD676 can operate at a 2 × F_S oversampling rate, where F_S = 48 kHz.

In quantized systems, the informational content of the analog input is represented in the frequency spectrum from dc to the Nyquist rate of the converter. Within this same spectrum are higher frequency noise and signal components. Antialias, or low pass, filters are used at the input to the ADC to reduce these noise and signal components so that their aliased components do not corrupt the baseband spectrum. However, wideband noise contributed by the AD676 will not be reduced by the antialias filter. The AD676 quantization noise is evenly distributed from dc to the Nyquist rate, and this fact can be used to minimize its overall affect.

The AD676 quantization noise effects can be reduced by oversampling—sampling at a rate higher than that defined by the Nyquist theorem. This spreads the noise energy over a bandwidth wider than the frequency band of interest. By judicious selection of a digital decimation filter, noise frequencies outside the bandwidth of interest may be eliminated.

The process of analog to digital conversion inherently produces noise, known as quantization noise. The magnitude of this noise is a function of the resolution of the converter, and manifests itself as a limit to the theoretical signal-to-noise ratio achievable. This limit is described by S/(N+D) = (6.02n + 1.76 + 10 log $F_S/2F_A$) dB, where n is the resolution of the converter in bits, F_S is the sampling frequency, and Fa is the signal bandwidth of interest. For audio bandwidth applications, the AD676 is capable of operating at a 2 × oversample rate (96 kSPS), which typically produces an improvement in S/(N+D) of 3 dB compared with operating at the Nyquist conversion rate of 48 kSPS. Oversampling has another advantage as well; the demands on the antialias filter are lessened. In summary, system performance is optimized by running the AD676 at or near its maximum sampling rate of 100 kHz and digitally filtering the resulting spectrum to eliminate undesired frequencies.

DC CODE UNCERTAINTY

Ideally, a fixed dc input should result in the same output code for repetitive conversions. However, as a consequence of system noise and circuit noise, for a given input voltage there is a range of output codes which may occur. Figure 9 is a histogram of the codes resulting from 1000 conversions of a typical input voltage by the AD676 used with a 10 V reference.

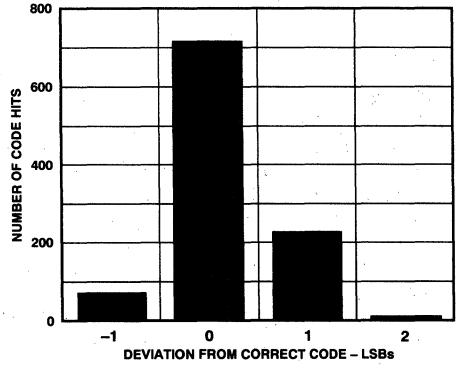

Figure 9. Distribution of Codes from 1000 Conversions, Relative to the Correct Code.

The standard deviation of this distribution is approximately 0.5 LSBs. If less uncertainty is desired, averaging multiple conversions will narrow this distribution by the inverse of the square root of the number of samples; i.e., the average of 4 conversions would have a standard deviation of 0.25 LSBs.

MICROPROCESSOR INTERFACE

The AD676 is ideally suited for use in both traditional dc measurement applications supporting a microprocessor, and in ac signal processing applications interfacing to a digital signal processor. The AD676 is designed to interface with a 16-bit data bus, providing all output data bits in a single read cycle. A variety of external buffers, such as 74HC541, can be used with the AD676 to provide 3-state outputs, high driving capability, and to prevent bus noise from coupling into the ADC. The following sections illustrate the use of the AD676 with a representative digital signal processor and microprocessor. These circuits provide general interface practices which are applicable to other processor choices.

ADSP-2101

Figure 10a shows the AD676 interfaced to the ADSP-2101 DSP processor. The AD676 buffers are mapped in the ADSP-2101's memory space, requiring one wait state when using a 12.5 MHz processor clock.

The falling edge of BUSY interrupts the processor, indicating that new data is ready. The ADSP-2101 automatically jumps to the appropriate service routine with minimal overhead. The interrupt routine then instructs the processor to read the new data using a memory read instruction.

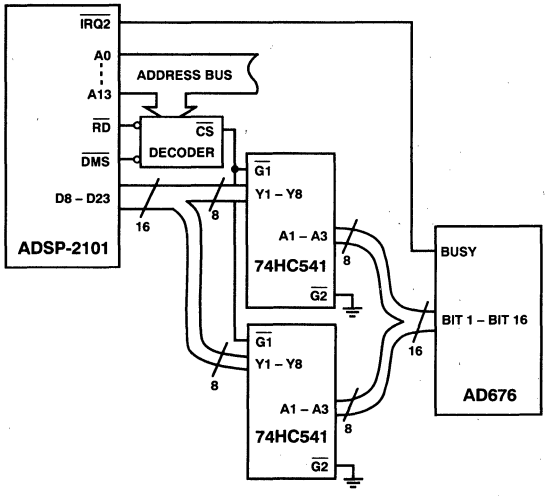

Figure 10a.

Figure 10b shows circuitry which would be included by a typical address decoder for the output buffers. In this case, a data memory access to any address in the range 3000H to 37FFH will result in the output buffers being enabled.

The AD676 CLK and SAMPLE can be generated by dividing down the system clock as described earlier (Figure 3), or if the ADSP-2101 serial port clocks are not being used, they can be programmed to generate CLK and SAMPLE.

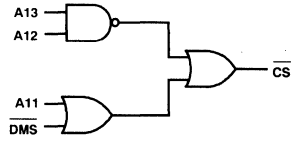

Figure 10b.

80286

The 80286 16-bit microprocessor can be interfaced to a buffered AD676 without any generation of wait states. As seen in Figure 11, BUSY can be used both to control the AD676 clock and to alert the processor when new data is ready. In the system shown, the 80286 should be configured in an edge triggered, direct interrupt mode (integrated controller provides the interrupt vector). Since the 80286 does not latch interrupt signals, the interrupt needs to be internally acknowledged before BUSY goes HIGH again during the next AD676 conversion (BUSY = 0). Depending on whether the AD676 buffers are mapped into memory or I/O space, the interrupt service routine will read the data by using either the MOV or the IN instruction. To be able to read all the 16 bits at once, and thereby increase the 80286's efficiency, the buffers should be located at an even address.

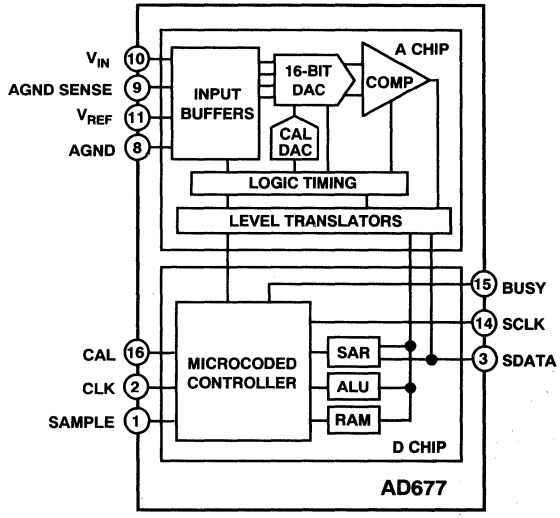
FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD677 is a multipurpose 16-bit serial output analog-to-digital converter which utilizes a switched-capacitor/charge redistribution architecture to achieve a 100 kSPS conversion rate (10 μs total conversion time). Overall performance is optimized by digitally correcting internal nonlinearities through on-chip autocalibration.

The AD677 circuitry is segmented onto two monolithic chips—a digital control chip fabricated on Analog Devices DSP CMOS process and an analog ADC chip fabricated on our BiMOS II process. Both chips are contained in a single package.

The AD677 is specified for ac (or "dynamic") parameters such as S/(N+D) Ratio, THD and IMD which are important in signal processing applications. In addition, dc parameters are specified which are important in measurement applications.

The AD677 operates from +5 V and ±12 V supplies and typically consumes 450 mW using a 10 V reference (360 mW with 5 V reference) during conversion. The digital supply (V_{DD}) is separated from the analog supplies (V_{CC}, V_{EE}) for reduced digital crosstalk. An analog ground sense is provided to remotely sense the ground potential of the signal source. This can be useful if the signal has to be carried some distance to the A/D converter. Separate analog and digital grounds are also provided.

The AD677 is available in a 16-pin narrow plastic DIP, 16-pin narrow side-brazed ceramic package, or 28-lead SOIC. A parallel output version, the AD676, is available in a 28-pin ceramic or plastic DIP. All models operate over a commercial temperature range of 0°C to +70°C or an industrial range of −40°C to +85°C.

PRODUCT HIGHLIGHTS

1. Autocalibration provides excellent dc performance while eliminating the need for user adjustments or additional external circuitry.
2. ±5 V to ±10 V input range ($\pm V_{REF}$).
3. Available in 16-pin 0.3″ skinny DIP or 28-lead SOIC.
4. Easy serial interface to standard ADI DSPs.
5. TTL compatible inputs/outputs.
6. Excellent ac performance: −99 dB THD, 92 dB S/(N+D), peak spurious −101 dB.
7. Industry leading dc performance: 1.0 LSB INL, ±1 LSB full scale and offset.

AD677—SPECIFICATIONS

AC SPECIFICATIONS (T_{MIN} to T_{MAX}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%)[1]

Parameter	AD677J/A Min	AD677J/A Typ	AD677J/A Max	AD677K/B Min	AD677K/B Typ	AD677K/B Max	Units

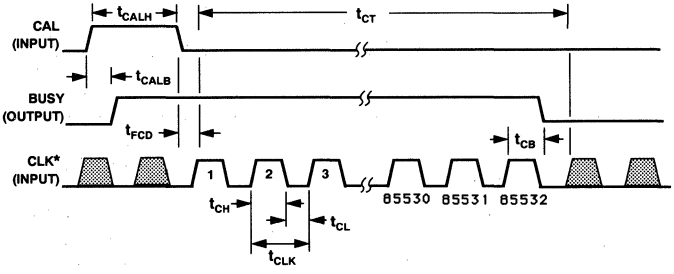
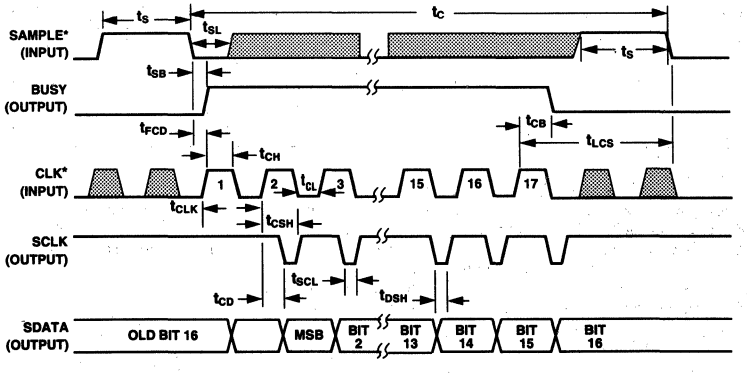
SDATA to SCLK High	t_{DSH}	50	80		ns
CAL High Time	t_{CALH}	50			ns
CAL to BUSY Delay	t_{CALB}		15	50	ns

NOTES
[1]See the "CONVERSION CONTROL" and "AUTOCALIBRATION" sections for detailed explanations of the above timing.
[2]Depends upon external clock frequency; includes acquisition time and conversion time. The maximum conversion period is specified to account for the droop of the internal sample/hold function. Operation at slower rates may degrade performance.
[3]$t_C = t_{FCD} + 16 \times t_{CLK} + t_{LCS}$
[4]580 ns is recommended for optimal accuracy over temperature (not necessary during calibration cycle).
[5]If SAMPLE goes high before the 17th CLK pulse, the device will start sampling approximately 100 ns after the rising edge of the 17th CLK pulse.
[6]$t_{CH} + t_{CL} = t_{CLK}$ and must be greater than 480 ns.



*SHADED PORTIONS OF INPUT SIGNALS ARE OPTIONAL. FOR BEST PERFORMANCE, WE RECOMMEND THAT THESE SIGNALS BE HELD LOW EXCEPT WHEN EXPLICITY SHOWN HIGH.

Figure 1. Calibration Timing



*SHADED PORTIONS OF INPUT SIGNALS ARE OPTIONAL. FOR BEST PERFORMANCE, WE RECOMMEND THAT THESE SIGNALS BE HELD LOW EXCEPT WHEN EXPLICITY SHOWN HIGH.

Soldering . . . . . +300°C, 10 sec
Storage Temperature . . . . . −65°C to +150°C

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD677 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN DESCRIPTION

DIP Pin	SOIC Pin	Type	Name	Description
1	1	SAMPLE	DI	V_{IN} Acquisition Control Pin. Active HIGH. During conversion, SAMPLE controls the state of the internal sample-hold amplifier and the falling edge initiates conversion. During calibration, SAMPLE should be held LOW. If HIGH during calibration, diagnostic information will appear on SDATA.
2	2	CLK	DI	Master Clock Input. The AD677 requires 17 clock pulses to execute a conversion. CLK is also used to derive SCLK.
3	3	SDATA	DO	Serial Output Data Controlled by SCLK.
4	6, 7	DGND	P	Digital Ground.
5	8	V_{CC}	P	+12 V Analog Supply Voltage.
8	12	AGND	P	Analog Ground.
9	15	AGND SENSE	AI	Analog Ground Sense.
10	16	V_{IN}	AI	Analog Input Voltage.
11	17	V_{REF}	A1	External Voltage Reference Input.
12	21	V_{EE}	P	−12 V Analog Supply Voltage.
13	22, 23	V_{DD}	P	+5 V Logic Supply Voltage.
14	26	SCLK	DO	Clock Output for Data Read, derived from CLK.
15	27	BUSY	DO	Status Line for Converter. Active HIGH, indicating a conversion or calibration in progress.
16	28	CAL	DI	Calibration Control Pin.
6, 7	4, 5, 9, 10, 11, 13, 14, 18, 19, 20, 24, 25	NC	–	No Connection. No connections should be made to these pins.

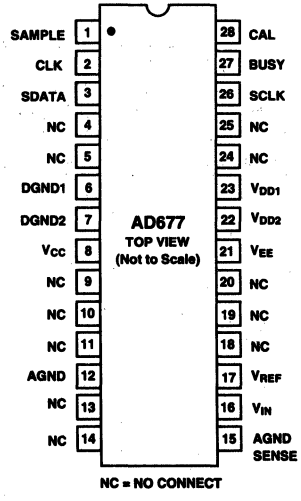
DIP Pinout



SOIC Pinout

NYQUIST FREQUENCY
An implication of the Nyquist sampling theorem, the "Nyquist frequency" of a converter is that input frequency which is one half the sampling frequency of the converter.

TOTAL HARMONIC DISTORTION
Total harmonic distortion (THD) is the ratio of the rms sum of the harmonic components to the rms value of a full-scale input signal and is expressed in percent (%) or decibels (dB). For input signals or harmonics that are above the Nyquist frequency, the aliased components are used.

SIGNAL-TO-NOISE PLUS DISTORTION RATIO
Signal-to-noise plus distortion is defined to be the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

+/– FULL-SCALE ERROR
The last + transition (from 011 . . . 10 to 011 . . . 11) should occur for an analog voltage 1.5 LSB below the nominal full scale (4.99977 volts for a ±5 V range). The full-scale error is the deviation of the actual level of the last transition from the ideal level.

BIPOLAR ZERO ERROR
Bipolar zero error is the difference between the ideal midscale input voltage (0 V) and the actual voltage producing the midscale output code.

DIFFERENTIAL NONLINEARITY (DNL)
In an ideal ADC, code transitions are one LSB apart. Differential nonlinearity is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

INTEGRAL NONLINEARITY (INL)
The ideal transfer function for an ADC is a straight line bisecting the center of each code drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the most negative code transition. "Full scale" is defined as a level 1.5 LSB beyond the most positive code transition. Integral nonlinearity is the worst-case deviation of a code center average from the straight line.

BANDWIDTH
The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb), and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude, and the peak value of their sum is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

APERTURE DELAY
Aperture delay is the time required after SAMPLE pin is taken LOW for the internal sample-hold of the AD677 to open, thus holding the value of V_{IN}.

APERTURE JITTER
Aperture jitter is the variation in the aperture delay from sample to sample.

POWER SUPPLY REJECTION
DC variations in the power supply voltage will affect the overall transfer function of the ADC, resulting in zero error and full-scale error changes. Power supply rejection is the maximum change in either the bipolar zero error or full-scale error value. Additionally, there is another power supply variation to consider. AC ripple on the power supplies can couple noise into the ADC, resulting in degradation of dynamic performance. This is displayed in Figure 15.

INPUT SETTLING TIME
Settling time is a function of the SHA's ability to track fast slewing signals. This is specified as the maximum time required in track mode after a full-scale step input to guarantee rated conversion accuracy.

NOISE/DC CODE UNCERTAINTY
Ideally, a fixed dc input should result in the same output code for repetitive conversions. However, as a consequence of unavoidable circuit noise within the wideband circuits in the ADC, there is a range of output codes which may occur for a given input voltage. If you apply a dc signal to the ADC and record a large number of conversions, the result will be a distribution of codes. If you fit a Gaussian probability distribution to the histogram, the standard deviation is approximately equivalent to the rms input noise of the ADC.

FUNCTIONAL DESCRIPTION

The AD677 is a multipurpose 16-bit analog-to-digital converter and includes circuitry which performs an input sample/hold function, ground sense, and autocalibration. These functions are segmented onto two monolithic chips—an analog signal processor and a digital controller. Both chips are contained within the AD677 package.

The AD677 employs a successive-approximation technique to determine the value of the analog input voltage. However, instead of the traditional laser-trimmed resistor-ladder approach, this device uses a capacitor-array, charge redistribution technique. Binary-weighted capacitors subdivide the input sample to perform the actual analog-to-digital conversion. The capacitor array eliminates variation in the linearity of the device due to temperature-induced mismatches of resistor values. Since a capacitor array is used to perform the data conversions, the sample/hold function is included without the need for additional external circuitry.

Initial errors in capacitor matching are eliminated by an autocalibration circuit within the AD677. This circuit employs an on-chip microcontroller and a calibration DAC to measure and compensate capacitor mismatch errors. As each error is determined, its value is stored in on-chip memory (RAM). Subsequent conversions use these RAM values to improve conversion accuracy. The autocalibration routine may be invoked at any time. Autocalibration insures high performance while eliminating the need for any user adjustments and is described in detail below.

The microcontroller controls all of the various functions within the AD677. These include the actual successive approximation algorithm, the autocalibration routine, the sample/hold operation, and the internal output data latch.

AUTOCALIBRATION

The AD677 achieves rated performance without the need for user trims or adjustments. This is accomplished through the use of on-chip autocalibration.

In the autocalibration sequence, sample/hold offset is nulled by internally connecting the input circuit to the ground sense circuit. The resulting offset voltage is measured and stored in RAM for later use. Next, the capacitor representing the most significant bit (MSB) is charged to the reference voltage. This charge is then transferred to a capacitor of equal size (composed of the sum of the remaining lower weight bits). The voltage that results represents the amount of capacitor mismatch. A calibration digital-to-analog converter (DAC) adds an appropriate value of error correction voltage to cancel this mismatch. This correction factor is also stored in RAM. This process is repeated for each of the eight remaining capacitors representing the top nine bits. The accumulated values in RAM are then used during subsequent conversions to adjust conversion results accordingly.

As shown in Figure 1, when CAL is taken HIGH the AD677 internal circuitry is reset, the BUSY pin is driven HIGH, and the ADC prepares for calibration. This is an asynchronous hardware reset and will interrupt any conversion or calibration currently in progress. Actual calibration begins when CAL is taken LOW and completes in 85,532 clock cycles, indicated by BUSY going LOW. During calibration, it is preferable for SAMPLE to be held LOW. If SAMPLE is HIGH, diagnostic data will appear on SDATA. This data is of no value to the user.

In most applications, it is sufficient to calibrate the AD677 only upon power-up, in which case care should be taken that the power supplies and voltage reference have stabilized first. If calibration is not performed, the AD677 may come up in an unknown state, or performance could degrade to as low as 10 bits.

CONVERSION CONTROL

The AD677 is controlled by two signals: SAMPLE and CLK, as shown in Figure 2. It is assumed that the part has been calibrated and the digital I/O pins have the levels shown at the start of the timing diagram.

A conversion consists of an input acquisition followed by 17 clock pulses which execute the 16-bit internal successive approximation routine. The analog input is acquired by taking the SAMPLE line HIGH for a minimum sampling time of t_S. The actual sample taken is the voltage present on V_{IN} one aperture delay after the SAMPLE line is brought LOW, assuming the previous conversion has completed (signified by BUSY going LOW). Care should be taken to ensure that this negative edge is well defined and jitter free in ac applications to reduce the uncertainty (noise) in signal acquisition. With SAMPLE going LOW, the AD677 commits itself to the conversion—the input at V_{IN} is disconnected from the internal capacitor array, BUSY goes HIGH, and the SAMPLE input will be ignored until the conversion is completed (when BUSY goes LOW). SAMPLE must be held LOW for a minimum period of time t_{SL}. A period of time t_{FCD} after bringing SAMPLE LOW, the 17 CLK cycles are applied; CLK pulses that start before this period of time are ignored. BUSY goes HIGH t_{SB} after SAMPLE goes LOW, signifying that a conversion is in process, and remains HIGH until the conversion is completed. As indicated in Figure 2, the twos complement output data is presented MSB first. This data may be captured with the rising edge of SCLK or the falling edge of CLK, beginning with pulse #2. The AD677 will ignore CLK after BUSY has gone LOW and SDATA or SCLK will not change until a new sample is acquired.

CONTINUOUS CONVERSION

For maximum throughput rate, the AD677 can be operated in a continuous convert mode. This is accomplished by utilizing the fact that SAMPLE will no longer be ignored after BUSY goes LOW, so an acquisition may be initiated even during the HIGH time of the 17th CLK pulse for maximum throughput rate while enabling full settling of the sample/hold circuitry. If SAMPLE is already HIGH during the rising edge of the 17th CLK, then an acquisition is immediately initiated approximately 100 ns after the rising edge of the 17th clock pulse.

Care must be taken to adhere to the minimum/maximum timing requirements in order to preserve conversion accuracy.

GENERAL CONVERSION GUIDELINES

During signal acquisition and conversion, care should be taken with the logic inputs to avoid digital feedthrough noise. It is possible to run CLK continuously, even during the sample period. However, CLK edges during the sampling period, and especially when SAMPLE goes LOW, may inject noise into the sampling process. The AD677 is tested with no CLK cycles during the sampling period. The BUSY signal can be used to prevent the clock from running during acquisition, as illustrated

in Figure 3. In this circuit BUSY is used to reset the circuitry which divides the system clock down to provide the AD677 CLK. This serves to interrupt the clock until after the input signal has been acquired, which has occurred when BUSY goes HIGH. When the conversion is completed and BUSY goes LOW, the circuit in Figure 3 truncates the 17th CLK pulse width which is tolerable because only its rising edge is critical.

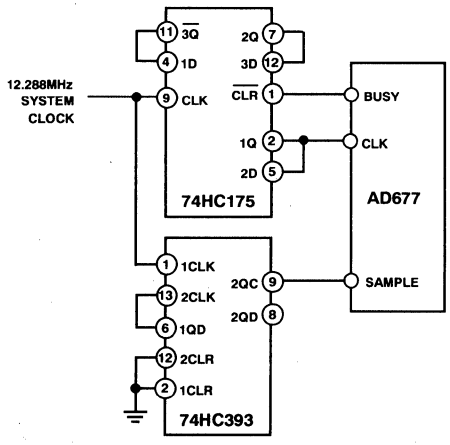


Figure 3.

Figure 3 also illustrates the use of a counter (74HC393) to derive the AD677 SAMPLE command from the system clock when a continuous convert mode is desirable. Pin 9 (2QC) provides a 96 kHz sample rate for the AD677 when used with a 12.288 MHz system clock. Alternately, Pin 8 (2QD) could be used for a 48 kHz rate.

If a continuous clock is used, then the user must avoid CLK edges at the instant of disconnecting V_{IN} which occurs at the falling edge of SAMPLE (see t_{FCD} specification). The duty cycle of CLK may vary, but both the HIGH (t_{CH}) and LOW (t_{CL}) phases must conform to those shown in the timing specifications. The internal comparator makes its decisions on the rising edge of CLK. To avoid a negative edge transition disturbing the comparator's settling, t_{CL} should be at least half the value of t_{CLK}. It is not recommended that the SAMPLE pin change state toward the end of a CLK cycle, in order to avoid transitions disturbing the internal comparator's settling.

During a conversion, internal dc error terms such as comparator voltage offset are sampled, stored on internal capacitors and used to correct for their corresponding errors when needed. Because these voltages are stored on capacitors, they are subject to leakage decay and so require refreshing. For this reason there is a maximum conversion time t_C (1000 μs). From the time SAMPLE goes HIGH to the completion of the 17th CLK pulse, no more than 1000 μs should elapse for specified performance. However, there is no restriction to the maximum time between individual conversions.

Output coding for the AD677 is twos complement as shown in Table I. The AD677 is designed to limit output coding in the event of out-of-range input.

Table I. Serial Output Coding Format (Twos Complement)

V_{IN}	Output Code

POWER SUPPLIES AND DECOUPLING

The AD677 has three power supply input pins. V_{CC} and V_{EE} provide the supply voltages to operate the analog portions of the AD677 including the capacitor DAC, input buffers and comparator. V_{DD} provides the supply voltage which operates the digital portions of the AD677 including the data output buffers and the autocalibration controller.

As with most high performance linear circuits, changes in the power supplies can produce undesired changes in the performance of the circuit. Optimally, well regulated power supplies with less than 1% ripple should be selected. The ac output impedance of a power supply is a complex function of frequency, and in general will increase with frequency. In other words, high frequency switching such as that encountered with digital circuitry requires fast transient currents which most power supplies cannot adequately provide. This results in voltage spikes on the supplies. If these spikes exceed the ±5% tolerance of the ±12 V supplies or the ±10% limits of the +5 V supply, ADC performance will degrade. Additionally, spikes at frequencies higher than 100 kHz will also degrade performance. To compensate for the finite ac output impedance of the supplies, it is necessary to store "reserves" of charge in bypass capacitors. These capacitors can effectively lower the ac impedance presented to the AD677 power inputs which in turn will significantly reduce the magnitude of the voltage spikes. For bypassing to be effective, certain guidelines should be followed. Decoupling capacitors, typically 0.1 μF, should be placed as closely as possible to each power supply pin of the AD677. It is essential that these capacitors be placed physically close to the IC to minimize the inductance of the PCB trace between the capacitor and the supply pin. The logic supply (V_{DD}) should be decoupled to digital common and the analog supplies (V_{CC} and V_{EE}) to analog common. The reference input is also considered as a power supply pin in this regard and the same decoupling procedures apply. These points are displayed in Figure 4.

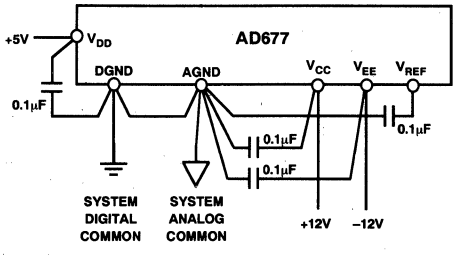

Figure 4. Grounding and Decoupling the AD677

Additionally, it is beneficial to have large capacitors (>47 μF) located at the point where the power connects to the PCB with 10 μF capacitors located in the vicinity of the ADC to further reduce low frequency ripple. In systems that will be subjected to particularly harsh environmental noise, additional decoupling may be necessary. RC-filtering on each power supply combined with dedicated voltage regulation can substantially decrease power supply ripple effects (this is further detailed in Figure 7).

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. A 1.22 mA current through a 0.5 Ω trace will develop a voltage drop of 0.6 mV, which is 4 LSBs at the 16-bit level for a 10 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals.

Analog and digital signals should not share a common return path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point at the AD677 to minimize interference between analog and digital circuitry. Analog signals should be routed as far as possible from digital signals and should cross them, if at all, only at right angles. A solid analog ground plane around the AD677 will isolate it from large switching ground currents. For these reasons, the use of wire wrap circuit construction will not provide adequate performance; careful printed circuit board construction is preferred.

GROUNDING

The AD677 has three grounding pins, designated ANALOG GROUND (AGND), DIGITAL GROUND (DGND) and ANALOG GROUND SENSE (AGND SENSE). The analog ground pin is the "high quality" ground reference point for the device, and should be connected to the analog common point in the system.

AGND SENSE is intended to be connected to the input signal ground reference point. This allows for slight differences in level between the analog ground point in the system and the input signal ground point. However no more than 100 mV is recommended between the AGND and the AGND SENSE pins for specified performance.

Using AGND SENSE to remotely sense the ground potential of the signal source can be useful if the signal has to be carried some distance to the A/D converter. Since all IC ground currents have to return to the power supply and no ground leads are free from resistance and inductance, there are always some voltage differences from one ground point in a system to another.

Over distance this voltage difference can easily amount to several LSBs (in a 10 V input span, 16-bit system each LSB is about 0.15 mV). This would directly corrupt the A/D input signal if the A/D measures its input with respect to power ground (AGND) as shown in Figure 5a. To solve this problem the AD677 offers an AGND SENSE pin. Figure 5b shows how the AGND SENSE can be used to eliminate the problem in Figure 5a. Figure 5b also shows how the signal wires should be

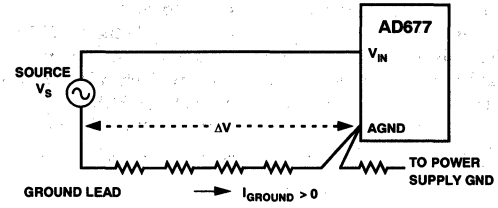

Figure 5a. Input to the A/D Is Corrupted by IR Drop in Ground Leads: $V_{IN} = V_S + \Delta V$.

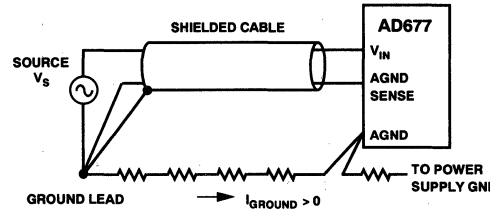

Figure 5b. AGND SENSE Eliminates the Problem in Figure 5a.

shielded in a noisy environment to avoid capacitive coupling. If inductive (magnetic) coupling is expected to be dominant such as where motors are present, twisted-pair wires should be used instead.

The digital ground pin is the reference point for all of the digital signals that operate the AD677. This pin should be connected to the digital common point in the system. As Figure 4 illustrated, the analog and digital grounds should be connected together at one point in the system, preferably at the AD677.

VOLTAGE REFERENCE

The AD677 requires the use of an external voltage reference. The input voltage range is determined by the value of the reference voltage; in general, a reference voltage of n volts allows an input range of ±n volts. The AD677 is specified for a voltage reference between +5 V and +10 V. A 10 V reference will typically require support circuitry operated from ±15 V supplies; a 5.0 V reference may be used with ±12 V supplies. Signal-to-noise performance is increased proportionately with input signal range (see Figure 12). In the presence of a fixed amount of system noise, increasing the LSB size (which results from increasing the reference voltage) will increase the effective S/(N+D) performance. Figure 11 illustrates S/(N+D) as a function of reference voltage. In contrast, dc accuracy will be optimal at lower reference voltage values (such as 5 V) due to capacitor nonlinearity at higher voltage values.

During a conversion, the switched capacitor array of the AD677 presents a dynamically changing current load at the voltage reference as the successive-approximation algorithm cycles through various choices of capacitor weighting. (See the following section "Analog Input" for a detailed discussion of the V_{REF} input characteristics.) The output impedance of the reference circuitry must be low so that the output voltage will remain sufficiently constant as the current drive changes. In some applications, this may require that the output of the voltage reference be buffered by an amplifier with low impedance at relatively high frequencies. In choosing a voltage reference, consideration should be

made for selecting one with low noise. A capacitor connected between REF IN and AGND will reduce the demands on the reference by decreasing the magnitude of high frequency components required to be sourced by the reference.

Figures 6 and 7 represent typical design approaches.

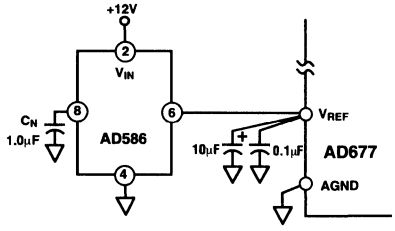

Figure 6.

Figure 6 shows a voltage reference circuit featuring the 5 V output AD586. The AD586 is a low cost reference which utilizes a buried Zener architecture to provide low noise and drift. Over the 0°C to +70°C range, the AD586M grade exhibits less than 1.0 mV output change from its initial value at +25°C. A noise-reduction capacitor, C_N, reduces the broadband noise of the AD586 output, thereby optimizing the overall performance of the AD677. It is recommended that a 10 µF to 47 µF high quality tantalum capacitor and a 0.1 µF capacitor be tied between the V_{REF} input of the AD677 and ground to minimize the impedance on the reference.

Using the AD677 with ±10 V input range (V_{REF} = 10 V) typically requires ±15 V supplies to drive op amps and the voltage reference. If ±12 V is not available in the system, regulators such as 78L12 and 79L12 can be used to provide power for the AD677. This is also the recommended approach (for any input range) when the ADC system is subjected to harsh environments such as where the power supplies are noisy and where voltage spikes are present. Figure 7 shows an example of such a system based upon the 10 V AD587 reference, which provides a 300 µV LSB. Circuitry for additional protection against power supply disturbances has been shown. A 100 µF capacitor at each

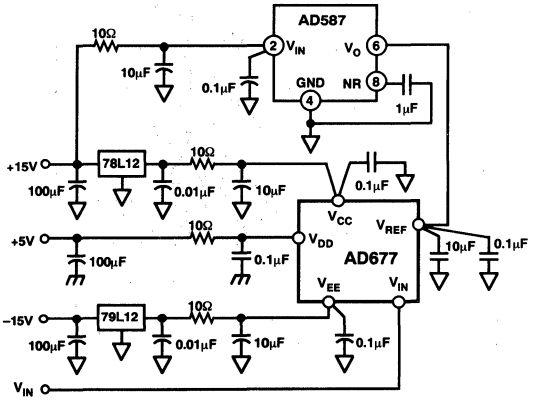

Figure 7.

regulator prevents very large voltage spikes from entering the regulators. Any power line noise which the regulators cannot eliminate will be further filtered by an RC filter (10 Ω/10 µF) having a −3 dB point at 1.6 kHz. For best results the regulators should be within a few centimeters of the AD677.

ANALOG INPUT

As previously discussed, the analog input voltage range for the AD677 is $\pm V_{REF}$. For purposes of ground drop and common mode rejection, the V_{IN} and V_{REF} inputs each have their own ground. V_{REF} is referred to the local analog system ground (AGND), and V_{IN} is referred to the analog ground sense pin (AGND SENSE) which allows a remote ground sense for the input signal.

The AD677 analog inputs (V_{IN}, V_{REF} and AGND SENSE) exhibit dynamic characteristics. When a conversion cycle begins, each analog input is connected to an internal, discharged 50 pF capacitor which then charges to the voltage present at the corresponding pin. The capacitor is disconnected when SAMPLE is taken LOW, and the stored charge is used in the subsequent conversion. In order to limit the demands placed on the external source by this high initial charging current, an internal buffer amplifier is employed between the input and this capacitance for a few hundred nanoseconds. During this time the input pin exhibits typically 20 kΩ input resistance, 10 pF input capacitance and ±40 µA bias current. Next, the input is switched directly to the now precharged capacitor and allowed to fully settle. During this time the input sees only a 50 pF capacitor. Once the sample is taken, the input is internally floated so that the external input source sees a very high input resistance and a parasitic input capacitance of typically only 2 pF. As a result, the only dominant input characteristic which must be considered is the high current steps which occur when the internal buffers are switched in and out.

In most cases, these characteristics require the use of an external op amp to drive the input of the AD677. Care should be taken with op amp selection; even with modest loading conditions, most available op amps do not meet the low distortion requirements necessary to match the performance capabilities of the AD677. Figure 8 represents a circuit, based upon the AD845, which will provide excellent overall performance.

For applications optimized more for low distortion and low noise, the AD845 of Figure 8 may be replaced by the AD743.

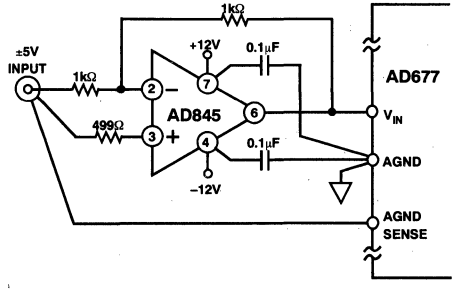

Figure 8.

AC PERFORMANCE

AC parameters, which include S/(N+D), THD, etc., reflect the AD677's effect on the spectral content of the analog input signal. Figures 11 through 18 provide information on the AD677's ac performance under a variety of conditions.

A perfect n-bit ADC with no errors will yield a theoretical quantization noise of $q/\sqrt{12}$, where q is the weight of the LSB. This relationship leads to the well-known equation for theoretical full-scale rms sine wave signal-to-noise plus distortion level of $S/(N + D) = 6.02\ n + 1.76$ dB, here n is the bit resolution. An actual ADC, however, will yield a measured S/(N + D) less than the theoretical value. Solving this equation for n using the measured S/(N + D) value yields the equation for effective number of bits (ENOB):

$$ENOB = \frac{[S/(N + D)]_{ACTUAL} - 1.76\ dB}{6.02}$$

As a general rule, averaging the results from several conversions reduces the effects of noise, and therefore improves such parameters as S/(N+D). AD677 performance may be optimized by operating the device at its maximum sample rate of 100 kSPS and digitally filtering the resulting bit stream to the desired signal bandwidth. This succeeds in distributing noise over a wider frequency range, thus reducing the noise density in the frequency band of interest. This subject is discussed in the following section.

OVERSAMPLING AND NOISE FILTERING

The Nyquist rate for a converter is defined as one-half its sampling rate. This is established by the Nyquist theorem, which requires that a signal be sampled at a rate corresponding to at least twice its highest frequency component of interest in order to preserve the informational content. Oversampling is a conversion technique in which the sampling frequency is more than twice the frequency bandwidth of interest. In audio applications, the AD677 can operate at a $2 \times F_S$ oversampling rate, where $F_S = 48$ kHz.

In quantized systems, the informational content of the analog input is represented in the frequency spectrum from dc to the Nyquist rate of the converter. Within this same spectrum are higher frequency noise and signal components. Antialias, or low pass, filters are used at the input to the ADC to reduce these noise and signal components so that their aliased components do not corrupt the baseband spectrum. However, wideband noise contributed by the AD677 will not be reduced by the antialias filter. The AD677 quantization noise is evenly distributed from dc to the Nyquist rate, and this fact can be used to minimize its overall affect.

The AD677 quantization noise effects can be reduced by oversampling—sampling at a rate higher than that defined by the Nyquist theorem. This spreads the noise energy over a bandwidth wider than the frequency band of interest. By judicious selection of a digital decimation filter, noise frequencies outside the bandwidth of interest may be eliminated.

The process of analog to digital conversion inherently produces noise, known as quantization noise. The magnitude of this noise is a function of the resolution of the converter, and manifests itself as a limit to the theoretical signal-to-noise ratio achievable. This limit is described by $S/(N+D) = (6.02n + 1.76 + 10 \log F_S/2F_A)$ dB, where n is the resolution of the converter in bits, F_S is the sampling frequency, and Fa is the signal bandwidth of interest. For audio bandwidth applications, the AD677 is capable of operating at a $2 \times$ oversample rate (96 kSPS), which typically produces an improvement in S/(N+D) of 3 dB compared with operating at the Nyquist conversion rate of 48 kSPS. Oversampling has another advantage as well; the demands on the antialias filter are lessened. In summary, system performance is optimized by running the AD677 at or near its maximum sampling rate of 100 kHz and digitally filtering the resulting spectrum to eliminate undesired frequencies.

DC PERFORMANCE

The self-calibration scheme used in the AD677 compensates for bit weight errors that may exist in the capacitor array. This mismatch in capacitor values is adjusted (using the calibration coefficients) during conversion and provides for excellent dc linearity performance. Figure 19 illustrates the DNL plot of a typical AD677 at +25°C. A histogram test is a statistical method for deriving an A/D converter's differential nonlinearity. A ramp input is sampled by the ADC and a large number of conversions are taken and stored. Theoretically the codes would all be the same size and, therefore, have an equal number of occurrences. A code with an average number of occurrences would have a DNL of "0". A code with more or less than average will have a DNL of greater than or less than zero LSB. A DNL of −1 LSB indicates missing code (zero occurrences).

Figure 20 illustrates the code width distribution of the DNL plots of Figure 19.

DC CODE UNCERTAINTY

Ideally, a fixed dc input should result in the same output code for repetitive conversions. However, as a consequence of unavoidable circuit noise within the wideband circuits in the ADC, there is range of output codes which may occur for a given input voltage. If you apply a dc signal to the AD677 and record 10,000 conversions, the result will be a distribution of codes as shown in Figure 9 (using a 10 V reference). If you fit a Gaussian probability distribution to the histogram, the standard deviation is approximately equivalent to the rms input noise of ADC.

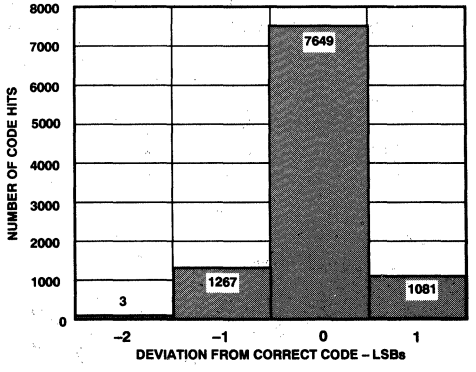

Figure 9. Distribution of Codes from 10,000 Conversions, Relative to the Correct Code

The standard deviation of this distribution is approximately 0.5 LSBs. If less uncertainty is desired, averaging multiple conversions will narrow this distribution by the inverse of the square root of the number of samples; i.e., the average of 4 conversions would have a standard deviation of 0.25 LSBs.

DSP INTERFACE

Figure 10 illustrates the use of the Analog Devices ADSP-2101 digital signal processor with the AD677. The ADSP-2101 FO (flag out) pin of Serial Port 1 (SPORT 1) is connected to the SAMPLE line and is used to control acquisition of data. The ADSP-2101 timer is used to provide precise timing of the FO pin.

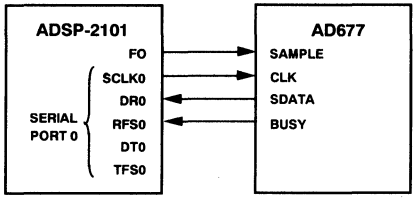

Figure 10. ADSP-2101 Interface

The SCLK pin of the ADSP-2101 SPORT0 provides the CLK input for the AD677. The clock should be programmed to be approximately 2 MHz to comply with AD677 specifications. To minimize digital feedthrough, the clock should be disabled (by setting Bit 14 in SPORT0 control register to 0) during data acquisition. Since the clock floats when disabled, a pull-down resistor of 12 kΩ–15 kΩ should be connected to SCLK to ensure it will be LOW at the falling edge of SAMPLE. To maximize the conversion rate, the serial clock should be enabled immediately after SAMPLE is brought LOW (hold mode).

The AD677 BUSY signal is connected to RF0 to notify SPORT0 when a new data word is coming. SPORT0 should be configured in normal, external, noninverting framing mode and can be programmed to generate an interrupt after the last data bit is received. To maximize the conversion rate, SAMPLE should be brought HIGH immediately after the last data bit is received.

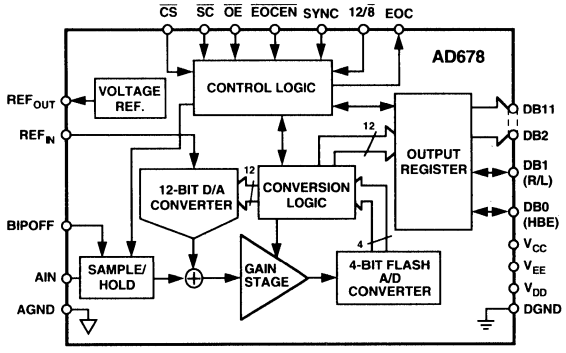
12-Bit 200 kSPS Complete Sampling ADC

AD678*

FEATURES

AC and DC Characterized and Specified (K, B and T Grades)
200k Conversions per Second
1 MHz Full Power Bandwidth
500 kHz Full Linear Bandwidth
72 dB S/N+D (K, B, T Grades)
Twos Complement Data Format (Bipolar Mode)
Straight Binary Data Format (Unipolar Mode)
10 MΩ Input Impedance
8-Bit or 16-Bit Bus Interface
On-Board Reference and Clock
10 V Unipolar or Bipolar Input Range
Commercial, Industrial and Military Temperature Range Grades
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD678 is a complete, multipurpose 12-bit monolithic analog-to-digital converter, consisting of a sample-hold amplifier (SHA), a microprocessor compatible bus interface, a voltage reference and clock generation circuitry.

The AD678 is specified for ac (or "dynamic") parameters such as S/N+D ratio, THD and IMD which are important in signal processing applications. In addition, the AD678K, B and T grades are fully specified for dc parameters which are important in measurement applications.

The AD678 offers a choice of digital interface formats; the 12 data bits can be accessed by a 16-bit bus in a single read operation or by an 8-bit bus in two read operations (8+4), with right or left justification. Data format is straight binary for unipolar mode and twos complement binary for bipolar mode. The input has a full-scale range of 10 V with a full power bandwidth of 1 MHz and a full linear bandwidth of 500 kHz. High input impedance (10 MΩ) allows direct connection to unbuffered sources without signal degradation.

This product is fabricated on Analog Devices' BiMOS process, combining low power CMOS logic with high precision, low noise bipolar circuits; laser-trimmed thin-film resistors provide high accuracy. The converter utilizes a recursive subranging algorithm which includes error correction and flash converter circuitry to achieve high speed and resolution.

The AD678 operates from +5 V and ±12 V supplies and dissipates 560 mW (typ). The AD678 is available in 28-pin plastic DIP, ceramic DIP, and 44 J-leaded ceramic surface mount packages.

Screening to MIL-STD-883C Class B is also available.

PRODUCT HIGHLIGHTS

1. COMPLETE INTEGRATION: The AD678 minimizes external component requirements by combining a high speed sample-hold amplifier (SHA), ADC, 5 V reference, clock and digital interface on a single chip. This provides a fully specified sampling A/D function unattainable with discrete designs.
2. SPECIFICATIONS: The AD678K, B and T grades provide fully specified and tested ac and dc parameters. The AD678J, A and S grades are specified and tested for ac parameters; dc accuracy specifications are shown as typicals. DC specifications (such as INL, gain and offset) are important in control and measurement applications. AC specifications (such as S/N+D ratio, THD and IMD) are of value in signal processing applications.
3. EASE OF USE: The pinout is designed for easy board layout, and the choice of single or two read cycle output provides compatibility with 16- or 8-bit buses. Factory trimming eliminates the need for calibration modes or external trimming to achieve rated performance.
4. RELIABILITY: The AD678 utilizes Analog Devices' monolithic BiMOS technology. This ensures long term reliability compared to multichip and hybrid designs.
5. UPGRADE PATH: The AD678 provides the same pinout as the 14-bit, 128 kSPS AD679 ADC.
6. The AD678 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD678/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD678—SPECIFICATIONS

AC SPECIFICATIONS (T_{min} to T_{max}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%, f_{SAMPLE} = 200 kSPS, f_{IN} = 10.06 kHz unless otherwise noted)[1]

Parameter	AD678J/A/S Min	AD678J/A/S Typ	AD678J/A/S Max	AD678K/B/T Min	AD678K/B/T Typ	AD678K/B/T Max	Units

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

ESD SENSITIVITY

The AD678 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD678 has been classified as a Category 1 device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual.*

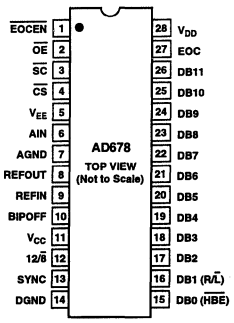
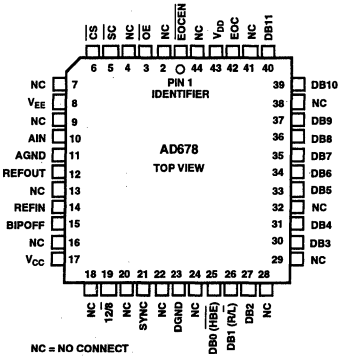
PIN CONFIGURATIONS

DIP Package



JLCC Package



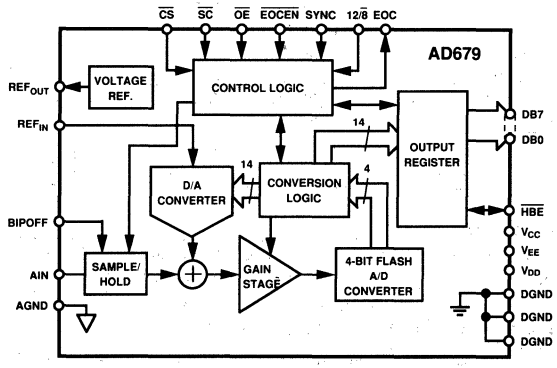
14-Bit 128 kSPS Complete Sampling ADC

AD679*

FEATURES

AC and DC Characterized and Specified (K, B, T Grades)
128k Conversions per Second
1 MHz Full Power Bandwidth
500 kHz Full Linear Bandwidth
80 dB S/N+D (K, B, T Grades)
Twos Complement Data Format (Bipolar Mode)
Straight Binary Data Format (Unipolar Mode)
10 MΩ Input Impedance
8-Bit Bus Interface (See AD779 for 16-Bit Interface)
On-Board Reference and Clock
10 V Unipolar or Bipolar Input Range
Pin Compatible with AD678 12-Bit, 200 kSPS ADC
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD679 is a complete, multipurpose 14-bit monolithic analog-to-digital converter, consisting of a sample-hold amplifier (SHA), a microprocessor compatible bus interface, a voltage reference and clock generation circuitry.

The AD679 is specified for ac (or "dynamic") parameters such as S/N+D ratio, THD and IMD which are important in signal processing applications. In addition, the AD679K, B and T grades are fully specified for dc parameters which are important in measurement applications.

The 14 data bits are accessed in two read operations (8+6), with left justification. Data format is straight binary for unipolar mode and twos complement binary for bipolar mode. The input has a full-scale range of 10 V with a full power bandwidth of 1 MHz and a full linear bandwidth of 500 kHz. High input impedance (10 MΩ) allows direct connection to unbuffered sources without signal degradation. Conversions can be initiated either under microprocessor control or by an external clock asynchronous to the system clock.

This product is fabricated on Analog Devices' BiMOS process, combining low power CMOS logic with high precision, low noise bipolar circuits; laser-trimmed thin-film resistors provide high accuracy. The converter utilizes a recursive subranging algorithm which includes error correction and flash converter circuitry to achieve high speed and resolution.

The AD679 operates from +5 V and ±12 V supplies and dissipates 560 mW (typ.). 28-pin plastic DIP, ceramic DIP and 44 J-leaded ceramic surface mount packages are available.

PRODUCT HIGHLIGHTS

1. COMPLETE INTEGRATION: The AD679 minimizes external component requirements by combining a high speed sample-hold amplifier (SHA), ADC, 5 V reference, clock and digital interface on a single chip. This provides a fully specified sampling A/D function unattainable with discrete designs.
2. SPECIFICATIONS: The AD679K, B and T grades provide fully specified and tested ac and dc parameters. The AD679J, A and S grades are specified and tested for ac parameters; dc accuracy specifications are shown as typicals. DC specifications (such as INL, gain and offset) are important in control and measurement applications. AC specifications (such as S/N+D ratio, THD and IMD) are of value in signal processing applications.
3. EASE OF USE: The pinout is designed for easy board layout, and the two read output provides compatibility with 8-bit buses. Factory trimming eliminates the need for calibration modes or external trimming to achieve rated performance.
4. RELIABILITY: The AD679 utilizes Analog Devices' monolithic BiMOS technology. This ensures long term reliability compared to multichip and hybrid designs.
5. UPGRADE PATH: The AD679 provides the same pinout as the 12-bit, 200 kSPS AD678 ADC.
6. The AD679 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD679/883B data sheet for detailed specifications.

NOTES

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[1]The AD679 is not designed to operate from ±15 V supplies.

ESD SENSITIVITY

The AD679 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD679 has been classified as a Category 1 device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual*.

ANALOG DEVICES

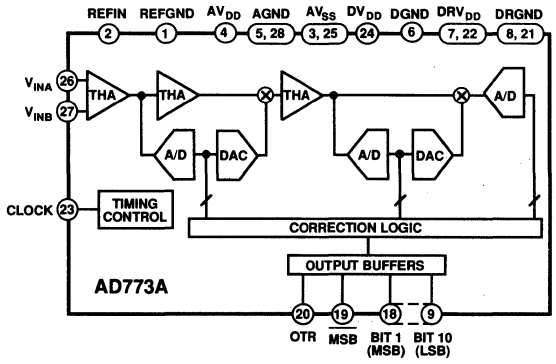
10-Bit 20 MSPS Monolithic A/D Converter

AD773A

FEATURES

- Monolithic 10-Bit 20 MSPS A/D Converter
- Low Power Dissipation: 1.0 W
- Signal-to-Noise Plus Distortion Ratio
  - f_{IN} = 1 MHz: 56 dB
  - f_{IN} = 10 MHz: 54 dB
- Guaranteed No Missing Codes
- On-Chip Track-and-Hold Amplifier
- 100 MHz Full Power Bandwidth
- High Impedance Reference Input
- Out of Range Output
- Twos Complement and Binary Output Data
- Available in Commercial and Military Temperature Ranges (See Military/Aerospace Reference Manual for Specifications)

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD773A is a monolithic 10-bit, 20 Msps analog-to-digital converter incorporating an on-board, high performance track-and-hold amplifier (THA). The AD773A converts video bandwidth signals without the use of an external THA. The AD773A implements a multistage differential pipelined architecture with output error correction logic. The AD773A offers accurate performance and guarantees no missing codes over the full operating temperature range.

Output data is presented in binary and twos complement format. An out of range (OTR) signal indicates the analog input voltage is beyond the specified input range. OTR can be decoded with the MSB/$\overline{\text{MSB}}$ pins to signal an underflow or overflow condition. The high impedance reference input allows multiple AD773As to be driven in parallel from a single reference.

The combined dc precision and dynamic performance of the AD773A is useful in a variety of applications. Typical applications include: video enhancement, HDTV, ghost cancellation, ultrasound imaging, radar and high speed data acquisition.

The AD773A was designed using Analog Devices' ABCMOS-1 process which utilizes high speed bipolar and 2-micron CMOS transistors on a single chip. High speed, precision analog circuits are now combined with high density logic circuits. Laser trimmed thin film resistors are used to optimize accuracy and temperature stability.

The AD773A is packaged in a 28-pin ceramic DIP and is available in commercial (0°C to +70°C) and military (−55°C to +125°C) grades.

PRODUCT HIGHLIGHTS

1. On-board THA
   The high impedance differential input THA eliminates the need for external buffering or sample and hold amplifiers. The THA offers the choice of differential or single-ended inputs. Input current is typically 5 μA.
2. High Impedance Reference Input
   The high impedance reference input (200 kΩ) allows direct connection with standard +2.5 V references, such as the AD680, AD580 and REF43.
3. Output Data Flexibility
   Output data is available in bipolar offset and bipolar twos complement binary format.
4. Out of Range (OTR)
   The OTR output bit indicates when the input signal is beyond the AD773A's input range.
5. Military Temperature Range

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD773A features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN DESCRIPTION

Symbol	Pin No.	Type	Name and Function
AGND	5, 28	P	Analog Ground.
AV_{DD}	4	P	+5 V Analog Supply.
AV_{SS}	3, 25	P	−5 V Analog Supply.
$\overline{MSB}$	19	DO	Inverted Most Significant Bit. Provides twos complement output data format.
OTR	20	DO	Out of Range is Active HIGH on the leading edge of Code 0 or the trailing edge of Code 1023. See Output Data Format Table II.
BIT 1 (MSB)	18	DO	Most Significant Bit.
BIT 2–BIT 9	17–10	DO	Data Bit 2 through Data Bit 9.
BIT 10 (LSB)	9	DO	Least Significant Bit.
CLK	23	DI	Clock Input. The AD773A will initiate a conversion on the falling edge of the clock input. See the Timing Diagram for details.
DV_{DD}	24	P	+5 V Digital Supply.
DRV_{DD}	7, 22	P	+5 V Digital Supply for the output drivers.
DGND	6	P	Digital Ground.
DRGND	8, 21	P	Digital Ground for the output drivers.
REFGND	1	AI	REFGND is connected to the ground of the external reference.
REFIN	2	AI	REFIN is the external 2.5 V reference input, taken with respect to REFGND.
V_{INA}	26	AI	(+) Analog input signal to the differential input THA.
V_{INB}	27	AI	(−) Analog input signal to the differential input THA.

Type: AI = Analog Input; DI = Digital Input; DO = Digital Output; P = Power.

INTEGRAL NONLINEARITY (INL)
Linearity error refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. The deviation is measured from the center of each particular code to the true straight line.

DIFFERENTIAL LINEARITY ERROR (DNL, NO MISSING CODES)
An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value.

ZERO EROR
The major carry transition should occur for an analog value 1/2 LSB below analog common. Zero error is defined as the deviation of the actual transition from that point.

GAIN ERROR
The first code transition should occur for an analog value 1/2 LSB above nominal negative full scale. The last transition should occur 1 1/2 LSB below the nominal positive full scale. Gain error is the deviation of the actual difference between first and last code transitions and the ideal difference between first and last code transitions.

POWER SUPPLY REJECTION
One of the effects of power supply variation on the performance of the device will be a change in gain error. The specification shows the maximum gain error deviation as the supplies are varied from their nominal values to their specified limits.

SIGNAL-TO-NOISE PLUS DISTORTION (S/N+D) RATIO
S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

EFFECTIVE NUMBER OF BITS (ENOB)
ENOB is calculated from the following expression:

S/N+D = 6.02N + 1.76, where N is equal to the effective number of bits.

TOTAL HARMONIC DISTORTION (THD)
THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

SPURIOUS FREE DYNAMIC RANGE
The peak spurious or peak harmonic component is the largest spectral component excluding the input signal and dc. This value is expressed in decibels relative to the rms value of a full-scale input signal.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa±nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa+fb) and (fa−fb) and the third order terms are (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

DIFFERENTIAL GAIN
The percentage difference between the output amplitudes of a small high frequency sine wave at two stated levels of a low frequency signal on which it is superimposed.

DIFFERENTIAL PHASE
The difference in the output phase of a small high frequency sine wave at two stated levels of a low frequency signal on which it is superimposed.

TRANSIENT RESPONSE
The time required for the AD773A to achieve its rated accuracy after a full-scale step function is applied to its input.

OVERVOLTAGE RECOVERY TIME
The time required for the ADC to recover to full accuracy after an analog input signal 150% of full scale is reduced to 50% of the full-scale value.

APERTURE DELAY
The difference between the switch delay and the analog delay of the THA. This effective delay represents the point in time, relative to the falling edge of the CLOCK input, that the analog input is sampled.

APERTURE JITTER
The variations in aperture delay for successive samples.

PIPELINE DELAY (LATENCY)
The number of clock cycles between conversion initiation and the associated output data being made available. New output data is provided every clock cycle.

FULL POWER BANDWIDTH
The input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

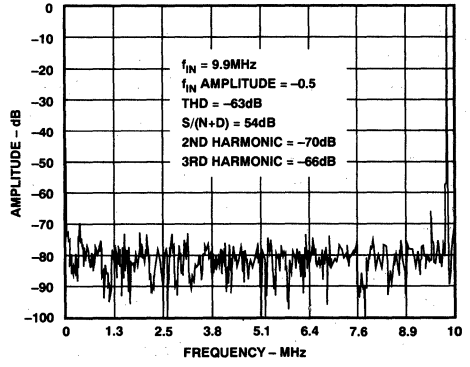

Figure 7. Typical FFT Plot of AD773A, f_{CLK} = 20 MSPS, f_{IN} = 9.9 MHz at 1 V p–p

Theory of Operation

The AD773A uses a pipelined multistage architecture with a differential input, fast settling track-and-hold amplifier (THA). Traditionally, high speed ADCs have used parallel, or flash architectures. When compared to flash converters, multistage architectures reduce the power dissipation and die size by reducing the number of comparators. For example, the AD773A uses 48 comparators compared to 1023 comparators for a 10-bit flash architecture.

The AD773A's main signal path transmits differential current mode signals. Low impedance current summing techniques are employed, increasing speed by reducing sensitivity to parasitic capacitances. Pipelining allows the stages to operate concurrently and maximizes system throughput.

The input THA is followed by three 4-bit conversion stages. At any given time, the first stage operates on the most recent sample, while the second stage operates on a signal dependent on the previous sample. This process continues throughout all three stages. The twelve digital bits provided by the three 4-bit stages are combined in the correction logic to produce a 10-bit representation of the sampled analog input.

Pipeline delay, or latency, is four clock cycles. New output data is provided every clock cycle and is provided in both binary and twos complement format. The AD773A will flag an out-of-range condition when the analog input exceeds the specified analog input range.

Applying the AD773A

DRIVING THE AD773A INPUT

The AD773A may be driven in a single-ended or differential fashion. V_{INA} is the positive input, and V_{INB} is the negative input. In the single-ended configuration either V_{INA} or V_{INB} is connected to Analog Ground (AGND) while the other input is driven with a full-scale input of ±500 mV p–p. An inverted mode of operation can be achieved by simply interchanging the input connections.

Both inputs of the AD773A, V_{INA} and V_{INB}, are high impedance and do not need to be driven by a low impedance source. Note, however, that as the source impedance increases, the input node becomes more susceptible to noise. The increased noise at the input will degrade performance. A 10 pF capacitor across V_{INA} and V_{INB} as shown in Figure 8 is recommended to bypass high frequency noise.

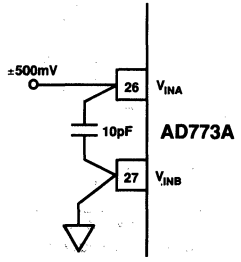

Figure 8. AD773A Single-Ended Input Connection

INPUT CONDITIONING

In some cases, it may be appropriate to buffer the input source, add dc offset, or otherwise condition the input signal of the AD773A. Choosing an appropriate op amp will vary with system requirements and the desired level of performance. Some suggested op amps are the AD9617, AD842, and AD827.

Figure 9 shows a typical application where a unipolar signal is level shifted to the bipolar input range of the AD773A. Note that the reference used with the AD773A can also provide a noise-free voltage source to generate the dc offset.

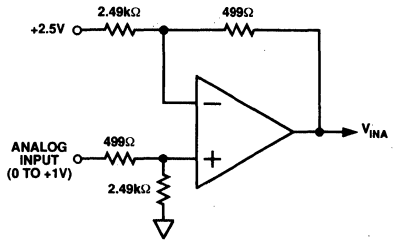

Figure 9. Unipolar to Bipolar Input Connection

DIFFERENTIAL INPUT CONNECTIONS

Operating the AD773A with fully differential inputs offers the advantage of rejecting common-mode signals present on both V_{INA} and V_{INB}. The full-scale input range of V_{INA} and V_{INB} when driven differentially is ±250 mV p–p as shown in Table I.

Table I. AD773A's Maximum Differential Input Voltage

V_{INA}	V_{INB}	V_{INA}–V_{INB}
+250 mV	−250 mV	+500 mV
−250 mV	+250 mV	−500 mV

In some applications it may be desirable to convert a single-ended signal to a differential signal before being applied to the AD773A. Figure 10 shows a single-ended to differential video line driver capable of driving doubly terminated cables.

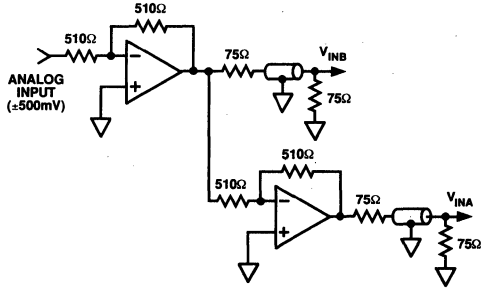

Figure 10. Single-Ended to Differential Connection

REFERENCE INPUT

The AD773A's high impedance reference input allows direct connection with standard voltage references. Unlike the resistor ladder requirements of a flash converter the AD773A's single pin, high impedance input can be driven from one low cost, low power reference. The high impedance input allows multiple AD773A's to be driven from one reference thus minimizing drift errors.

Figure 11 shows the AD773A connected to the AD680. The AD680 is a single supply, low power, low cost 2.5 V reference with performance specifications ideally suited for the AD773A. The low pass filter minimizes the AD680's wideband noise. Other recommended 2.5 V references are the AD580 and REF43.

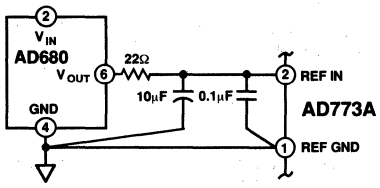

Figure 11. Recommended AD773A to AD680 Connection

CLOCK INPUT

The AD773A's pipelined architecture operates on both the rising and falling edges of the clock input. A low jitter, symmetrical clock will provide the highest level of performance. The recommended logic family to drive the clock input is HC. The AD773A's minimum clock half cycle may necessitate the use of an external divide-by-two circuit as shown in Figure 12. Power dissipation will vary with input clock frequency as shown in Figure 13.

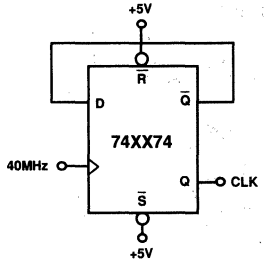

Figure 12. Divide-by-Two Clock Circuit

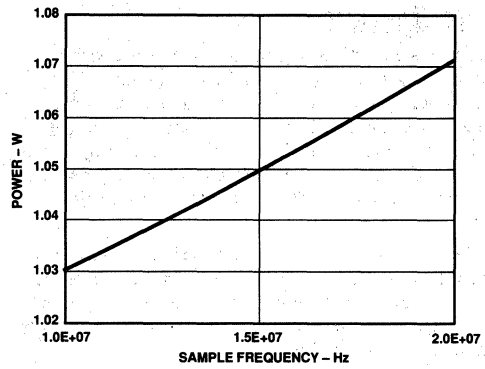

Figure 13. Power Dissipation vs. Sample Frequency

EQUIVALENT ANALOG INPUT CIRCUIT

The AD773A equivalent analog input circuit is shown in Figure 14. The typical input bias current is 5 μA, while input capacitance is typically 5 pF. In the single-ended input configuration one input is connected to AGND while the second input is driven to full scale (±500 mV). Under nominal conditions the collector of the input transistor is at +1.15 V. This allows signals to be offset by up to +0.65 V without significantly degrading performance. In the negative direction, the emitter of the input transistor should not drop below −1.25 V. Therefore, signals can be offset by −0.65 V without significant performance degradation. Figure 15 shows signal-to-noise ratio vs. common-mode input voltage.

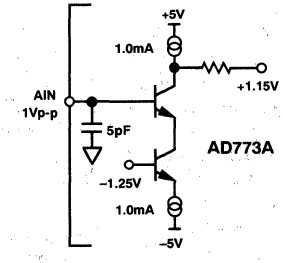

Figure 14. Equivalent Analog Input Circuit

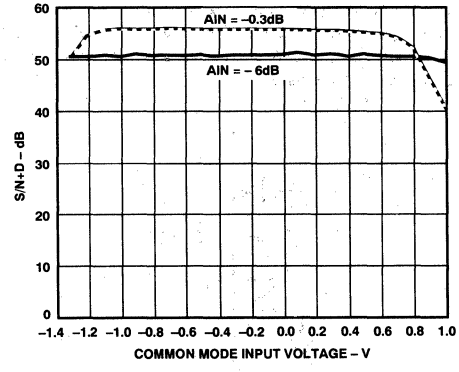

Figure 15. S/N+D vs. Common-Mode Input Voltage, f_{CLK} = 20 MSPS

EQUIVALENT REFERENCE INPUT CIRCUIT

The AD773A is designed to have a reference to analog input voltage ratio of 2.5:1. When the AD773A is configured for single-ended operation a 2.5 volt reference input establishes a full-scale analog input voltage of 1 V p–p (±500 mV with respect to V_{INB}). Although the AD773A is specified and tested with V_{REF} equal to 2.5 V and V_{IN} equal to ±500 mV the reference input voltage and analog input voltages can be changed. To optimize the AD773A's performance the 2.5:1 ratio should be maintained. The simplified model of the AD773A's reference input circuit is shown in Figure 16.

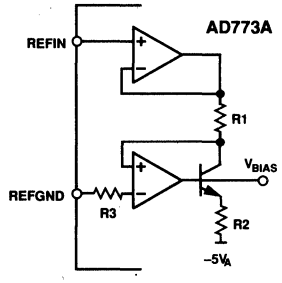

Figure 16. Typical Reference Input Circuit

The 2.5 V external reference is applied across resistor R1 producing a current which in turn generates a voltage V_{BIAS}. Multiple reference currents are generated from V_{BIAS} and are used throughout the converter. R3 is used to cancel errors induced by the input bias current of the REFGND buffer. Figure 17 shows the SNR performance as the reference voltage is varied from its nominal value of 2.5 V. The input full-scale voltage is defined by the following equation,

$$\textit{Input Full-Scale Voltage} = \frac{\textit{Reference Voltage}}{2.5}$$

The power dissipation is modulated by variations in the reference voltage. Figure 18 shows the variation in power dissipation versus reference voltage.

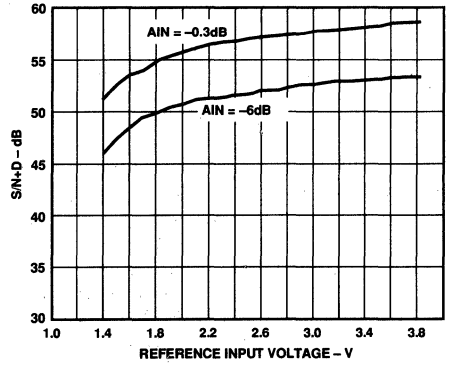

Figure 17. S/N+D vs. Reference Input Voltage, f_{CLK} = 20 MSPS, f_{IN} = 1 MHz

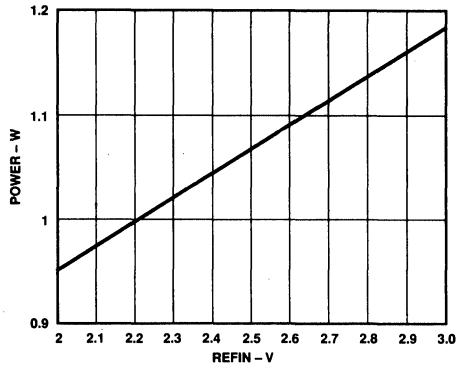

Figure 18. Power Dissipation vs. Reference Input Voltage, f_{CLOCK} = 20 MSPS

TRANSIENT RESPONSE

The fast settling input THA accurately converts full-scale input voltage swings in under one clock cycle. The THA's high impedance, fast slewing performance is critical in multiplexed or dc stepped (charge coupled devices, infrared detectors) systems. Figure 19 show the AD773A's settling performance with an input signal stepped from −500 mV to 0 V. As can be seen, the output code settles to its final value in under one clock cycle.

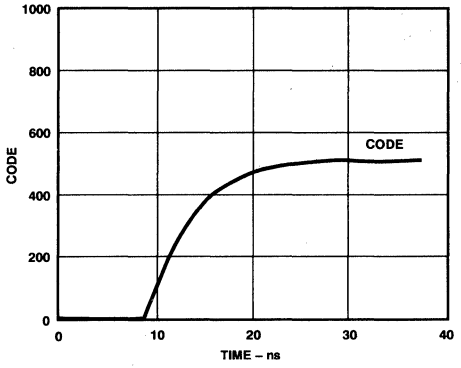

Figure 19. Typical AD773A Settling Time

OUTPUT DATA FORMAT

The AD773A provides both MSB and $\overline{MSB}$ outputs, delivering positive true offset binary and twos complement output data. Table II shows the AD773A's output data format.

Table II. Output Data Format

Analog Input	Digital Output		
V_{INA}–V_{INB}	Offset Binary	Twos Complement	OTR
≥499.5 mV	11 1111 1111	01 1111 1111	1
499 mV	11 1111 1111	01 1111 1111	0
0 mV	10 0000 0000	00 0000 0000	0
−500 mV	00 0000 0000	10 0000 0000	0
≤−500.5 mV	00 0000 0000	10 0000 0000	1

OUT OF RANGE

An out-of-range condition exists when the analog input voltage is beyond the input range (±500 mV) of the converter. [Note the AD773A has a 4 clock cycle latency.] OTR (Pin 20) is set low when the analog input voltage is within the analog input range. OTR is set HIGH and will remain HIGH when the analog input voltage exceeds the input range by 1/2 LSB from the center of the ± full-scale output codes. OTR will remain HIGH until the analog input is within the input range. Note that if the input is driven beyond +1.5 V, the digital outputs may not stay at +FS, but may actually fold back to midscale. By logical ANDing OTR with the MSB and its complement, overrange high or underrange low conditions can be detected. Table III is a truth table for the over/under range circuit in Figure 20. Systems requiring programmable gain conditioning prior to the AD773A can immediately detect an out of range condition, thus eliminating gain selection iterations.

1	1	Overrange

GROUNDING AND LAYOUT RULES

As is the case for any high performance device, proper grounding and layout techniques are essential in achieving optimal performance. (Note—Figures 22–26 are not to scale.) The analog and digital grounds on the AD773A have been separated to optimize the management of return currents in a system. It is recommended that a 4-layer printed circuit board (PCB) which employs ground planes and power planes be used with the AD773A. The use of ground and power planes offers distinct advantages:

1. The minimization of the loop area encompassed by a signal and its return path.
2. The minimization of the impedance associated with ground and power paths.
3. The inherent distributed capacitor formed by the power plane, PCB insulation, and ground plane.

These characteristics result in both a reduction of electromagnetic interference (EMI) and an overall improvement in performance.

It is important to design a layout which prevents noise from coupling onto the input signal. The wide input bandwidth of the AD773A permits noise outside the desired Nyquist bandwidth to be sampled along with the desired signal. This can result in a higher overall level of spurious noise in the digitized output. Digital signals should not be run in parallel with the circuitry. It is also suggested that the traces associated with V_{INA} and V_{INB} be the same length.

Separate analog and digital grounds should be joined together directly under the AD773A (see Figure 24). A solid ground plane under the AD773A is also acceptable if care is taken in the management of the power and ground return currents. A general "rule-of-thumb" for mixed signal layouts dictates that the return currents from digital circuitry should not pass through critical analog circuitry.

POWER SUPPLY DECOUPLING

The analog and digital supplies of the AD773A have been separated to prevent the typically large transients associated with digital circuitry from coupling into the analog supplies (AV_{DD}, AV_{SS}). Each analog power supply pin should be decoupled with a 0.1 μF capacitor located as close to the pin as possible. Additionally, 0.22 μF capacitors for the DRV_{DD} and DV_{DD} supplies are required to adequately suppress high frequency noise. For optimal performance, surface-mount capacitors are recommended. The inductance associated with the leads of through-hole ceramic capacitors typically render them ineffective at higher frequencies. A *complete* system will also incorporate tantalum capacitors in the 10–100 μF range to decouple low frequency noise and ferrite beads to limit high frequency noise.

The digital supplies have also been separated into DRV_{DD} and DV_{DD}. The DRV_{DD} pins provide power for the digital output drivers of the AD773A and are likely to contain high energy transients. Pin 22 should be decoupled directly to Pin 21 (DRGND) and Pin 7 should be decoupled directly to Pin 8 (DRGND) to minimize the length of the return path for these transients. A single +5 V supply is all that is required for DRV_{DD} and DV_{DD}, but decoupling DV_{DD} with an RC filter network is suggested (see Figure 21).

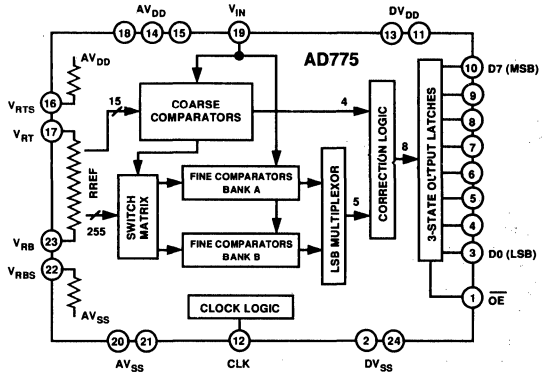
8-Bit 20 MSPS, 60 mW Sampling A/D Converter

AD775

FEATURES

CMOS 8-Bit 20 MSPS Sampling A/D Converter
Low Power Dissipation: 60 mW
+5 V Single Supply Operation
Differential Nonlinearity: 0.3 LSB
Differential Gain: 1%
Differential Phase: 0.5 Degrees
Three-State Outputs
On-Chip Reference Bias Resistors
Adjustable Reference Input
Video Industry Standard Pinout
Small Packages:
24-Pin, 300 Mil SOIC Surface Mount
24-Pin, 400 Mil Plastic DIP

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD775 is a CMOS, low power, 8-bit, 20 Msps sampling analog-to-digital converter (ADC). The AD775 features a built-in sampling function and on-chip reference bias resistors to provide a complete 8-bit ADC solution. The AD775 utilizes a pipelined/ping pong two-step flash architecture to provide high sampling rates (up to 35 MHz) while maintaining very low power consumption (60 mW).

Its combination of excellent DNL, fast sampling rate, low differential gain and phase errors, extremely low power dissipation, and single +5 V supply operation make it ideally suited for a variety of video and image acquisition applications, including portable equipment. The AD775's reference ladder may be connected in a variety of configurations to accommodate different input ranges. The low input capacitance (11 pF typical) provides an easy-to-drive input load compared to conventional flash converters.

The AD775 is offered in both 300 mil SOIC and 400 mil DIP plastic packages, and is designed to operate over an extended commercial temperature range (−20°C to +75°C).

PRODUCT HIGHLIGHTS

Low Power: The AD775 has a typical supply current of 12 mA, for a power consumption of 60 mW. Reference ladder current is also low: 6.6 mA typical, minimizing the reference power consumption.

Complete Solution: The AD775's switched capacitor design features an inherent sample/hold function: no external SHA is required. On-chip reference bias resistors are included to allow a supply-based reference to be generated without any external resistors.

Excellent Differential Nonlinearity: The AD775 features a typical DNL of 0.3 LSBs, with a maximum limit of 0.5 LSBs. No missing codes is guaranteed.

Single +5 V Supply Operation: The AD775 is designed to operate on a single +5 V supply, and the reference ladder may be configured to accommodate analog inputs inclusive of ground.

Low Input Capacitance: The 11 pF input capacitance of the AD775 can significantly decrease the cost and complexity of input driving circuitry, compared with conventional 8-bit flash ADCs.

*For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD775 features ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

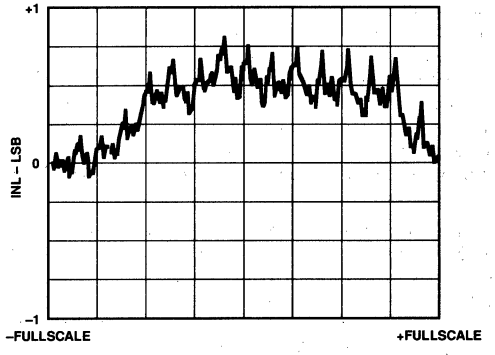

Figure 7. Typical Integral Nonlinearity (INL)

DEFINITIONS OF SPECIFICATIONS

Integral Nonlinearity (INL)

Integral nonlinearity refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. The deviation is measured from the center of each particular code to the true straight line.

Differential Nonlinearity (DNL, No Missing Codes)

An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. It is often specified in terms of the resolution for which no missing codes (NMC) is guaranteed.

Offset Error

The first code transition should occur at a level 1/2 LSB above nominal negative full scale. Offset referred to the Bottom of Ladder V_{RB} is defined as the deviation from this ideal. The last code transition should occur 1 1/2 LSB below the nominal positive full scale. Offset referred to the Top of Ladder V_{RT} is defined as the deviation from this ideal.

Differential Gain

The percentage difference between the output amplitudes of a small high frequency sine wave at two stated levels of a low frequency signal on which it is superimposed.

Differential Phase

The difference in the output phase of a small high frequency sine wave at two stated levels of a low frequency signal on which it is superimposed.

Pipeline Delay (Latency)

The number of clock cycles between conversion initiation and the associated output data being made available. New output data is provided every clock cycle.

Signal-to-Noise Plus Distortion Ratio (S/N+D)

S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

THEORY OF OPERATION

The AD775 uses a pipelined two-step (subranging) flash architecture to achieve significantly lower power and lower input capacitance than conventional full flash converters while still maintaining high throughput. The analog input is sampled by the switched capacitor comparators on the falling edge of the input clock: no external sample and hold is required. The coarse comparators determine the top four bits (MSBs), and select the appropriate reference ladder taps for the fine comparators. With the next falling edge of the clock, the fine comparators determine the bottom four bits (LSBs). Since the LSB comparators require a full clock cycle between their sampling instant and their decision, the converter alternates between two sets of fine comparators in a "ping-pong" fashion. This multiplexing allows a new input sample to be taken on every falling clock edge, thereby providing 20 Msps operation. The data is accumulated in the correction logic and output through a three-state output latch on the rising edge of the clock. The latency between input sampling and the corresponding converted output is 2.5 clock cycles.

All three comparator banks utilize the same resistive ladder for their reference input. The analog input range is determined by the voltages applied to the bottom and top of the ladder, and the AD775 can digitize inputs down to 0 V using a single supply. On-chip application resistors are provided to allow the ladder to be conveniently biased by the supply voltage.

The AD775 uses switched capacitor auto-zeroing techniques to cancel the comparators' offsets and achieve excellent differential nonlinearity performance: typically ±0.3 LSB. The integral nonlinearity is determined by the linearity of the reference ladder and is typically +0.5 LSB.

APPLYING THE AD775

REFERENCE INPUT

The AD775 features a resistive reference ladder similar to that found in most conventional flash converters. The analog input range of the converter falls between the top (V_{RT}) and bottom (V_{RB}) voltages of this ladder. The nominal resistance of the ladder is 300 ohms, though this may vary from 230 ohms to 450 ohms. The minimum recommended voltage for V_{RB} is 0 V; the linearity performance of the converter may deteriorate for input spans (V_{RB}–V_{RB}) below 1.8 V. While 2.8 V is the recommended maximum ladder top voltage (V_{RT}), the top of the ladder may be as high as the positive supply voltage (AV_{DD}) with minimal linearity degradation.

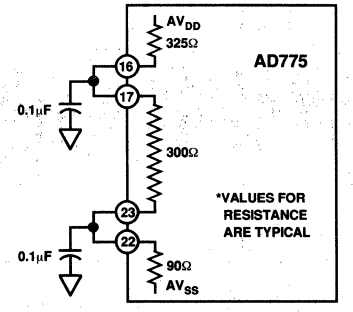

Figure 8. Reference Configuration: 0.64 V to 2.73 V

To simplify biasing of the AD775, on-chip reference bias resistors are provided on Pins 16 and 22. The two recommended configurations for these resistors are shown in Figures 8 and 9.

In the topology shown in Figure 8, the top of the ladder (V_{RT}) is shorted to the top bias resistor (V_{RTS}) (Pin 17 shorted to Pin 16), while the bottom of the ladder (V_{RB}) is shorted to the bottom bias resistor (V_{RBS}) (Pin 23 shorted to Pin 22). This creates a resistive path (nominally 725 ohms) between AV_{DD} and AV_{SS}. For nominal supply voltages (5 V and 0 V respectively), this creates an input range of 0.64 V to 2.73 V.

Both top and bottom of the reference ladder should be decoupled, preferably with a chip capacitor to ground to minimize reference noise.

The topology shown in Figure 9 provides a ground-inclusive input range. The bottom of the ladder (V_{RB}) is shorted to AV_{SS}. (0 V), while the top of the ladder (V_{RT}) is connected to the on-board bias resistor (V_{RTS}). This provides a nominal input range of 0 V to +2.4 V for AV_{DD} of 5 V. The V_{RBS} pin may be left floating, or shorted to AV_{SS}.

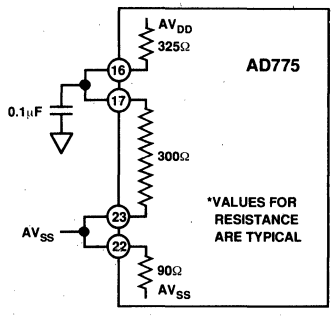

Figure 9. Reference Configuration: 0 V to +2.4 V

More elaborate topologies can be used for those wishing to provide an input span based on an external reference voltage. The circuit in Figure 10 uses the AD780 2.5 V reference to drive the top of the ladder (V_{RT}), with the bottom (V_{RB}) of the ladder grounded to provide an input span of 0 V to +2.5 V. This is modified in Figure 11 to shift the 2.5 V span up 700 mV.

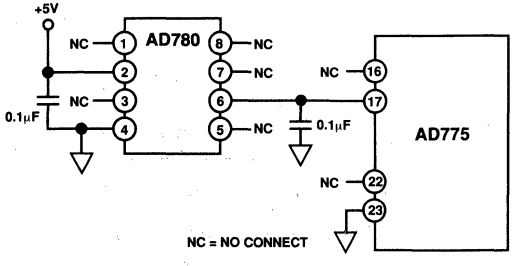

Figure 10. Reference Configuration: 0 V to 2.5V

The AD775 can accommodate dynamic changes in the reference voltage for gain or offset adjustment. However, conversions that are in progress, including those in the converter pipeline, while the reference voltages are changing will be invalid.

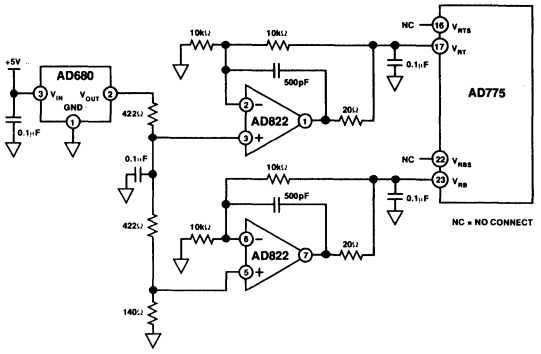

Figure 11. Reference Configuration: 0.7 V to 3.2 V

ANALOG INPUT

The impedance looking into the analog input is essentially capacitive, as shown in the equivalent circuit of Figure 12, typically totalling around 11 pF. A portion of this capacitance is parasitic; the remainder is part of the switched capacitor structure of the comparator arrays. The switches close on the rising edge of the clock, acquire the input voltage, and open on the clock's falling edge (the sampling instant). The charge that must be moved onto the capacitors during acquisition will be a function of the converter's previous two samples, but there should be no sample-to-sample crosstalk so long as ample driving impedance and acquisition time are provided.

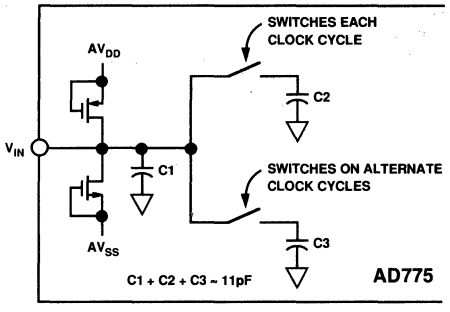

Figure 12. Equivalent Analog Input Circuit (V_{IN})

For example, to ensure accurate acquisition (to 1/4 bit accuracy) of a full-scale input step in less than 20 ns, a source impedance of less than 100 ohms is recommended. Figure 13 shows one option of input buffer circuitry using the AD817. The AD817 acts as both an inverting buffer and level shifting circuit. In order to level shift the ground-based input signal to the dc level required by the input of the AD775, the supply voltage is resistively divided to produce the appropriate voltage at the noninverting input of the AD817. For most applications, the AD817 provides a low cost, high performance level shifter. The AD811 is recommended for systems which require faster settling times.

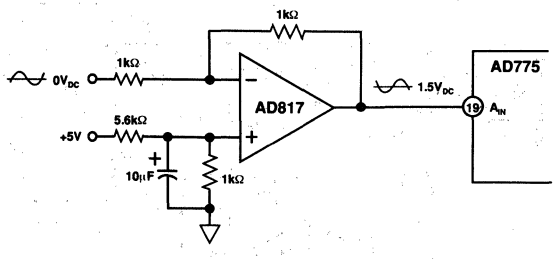

Figure 13. Level Shifting Input Buffer

The analog input range is set by the voltage at the top and bottom of the reference ladder. In general, the larger the span (V_{RT}–V_{RB}), the better the differential nonlinearity (DNL) of the converter; a 1.8 V span is suggested as a minimum to realize good linearity performance. As the input voltage exceeds 2.8 V (for AV_{DD} = 4.75 V), the input circuitry may start to slightly degrade the acquisition performance.

CLOCK INPUT

The AD775's internal control circuitry makes use of both clock edges to generate on-chip timing signals. To ensure proper settling and linearity performance, both t_{CH} and t_{CL} times should be 25 ns or greater. For sampling frequencies at or near 20 Msps, a 50% duty cycle clock is recommended. For slower sampling applications, the AD775 can accommodate a wider range of duty cycles, provided each clock phase is as least 25 ns.

Under certain conditions, the AD775 can be operated at sampling rates above 20 Msps. Figure 14 shows the signal-to-noise plus distortion (S/(N+D)) performance of a typical AD775 versus clock frequency. It is extremely important to note that *the maximum clock rate will be a strong function of both temperature and supply voltage*. In general, the part slows down with increasing temperature and decreasing supply voltage.

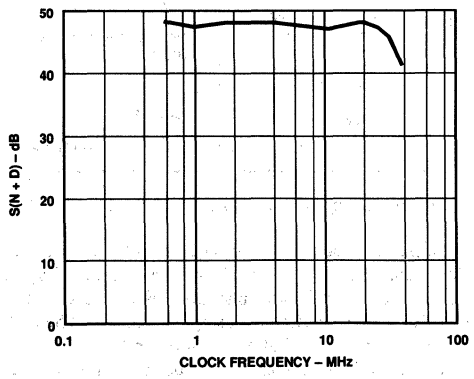

Figure 14. S(N+D) vs. Clock Frequency (Temperature = +25°C)

A significant portion of the AD775's power dissipation is proportional to the clock frequency: Figure 15 illustrates this tradeoff for a typical part.

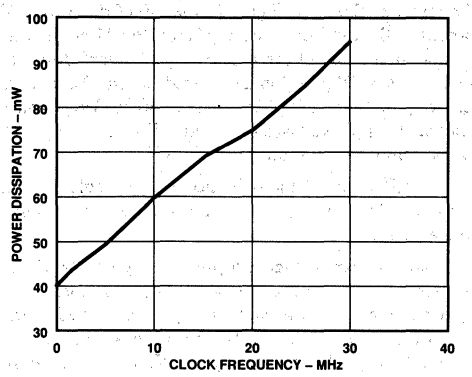

Figure 15. Power Dissipation vs. Clock Frequency

In applications sensitive to aperture jitter, the clock signal should have a fall time of less than 3 ns. High speed CMOS logic families (HC/HCT) are recommended for their symmetrical swing and fast rise/fall times. Care should be taken to minimize the fanout and capacitive loading of the clock input line.

DIGITAL INPUTS AND OUTPUTS

The AD775's digital interface uses standard CMOS, with logic thresholds roughly midway between the supplies (DV_{SS}, DV_{DD}). The digital output is presented in straight binary format, with full scale (1111 1111) corresponding to V_{IN} = V_{RT}, and zero (0000 0000) corresponding to V_{IN} = V_{RB}. Excessive capacitive loading of the digital output lines will increase the dynamic power dissipation as well as the on-chip digital noise. Logic fanout and parasitic capacitance on these lines should be minimized for optimum noise performance.

The data output lines may be placed in a high output impedance state by bringing $\overline{OE}$ (Pin 1) to a logic high. Figure 16 indicates typical timing for access and float delay times (t_{HL} and t_{DD} respectively). Note that even when the outputs are in a high impedance state, activity on the digital bus can couple back to the sensitive analog portions of the AD775 and corrupt conversions in progress.

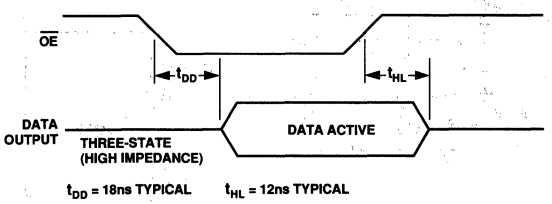

Figure 16. High Impedance Output Timing

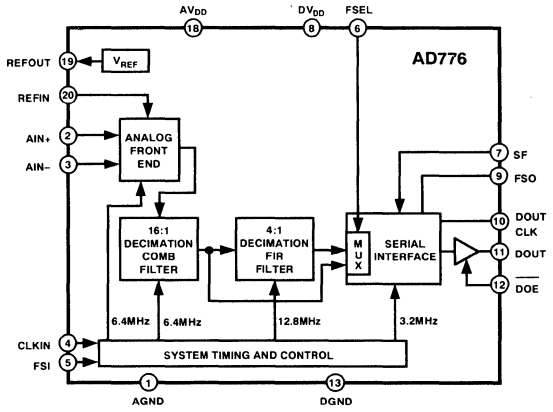
16-Bit 100 kSPS Oversampling ADC

AD776

FEATURES
Monolithic 16-Bit Sigma-Delta ADC
Third-Order Noise Shaping
96 dB Dynamic Range
90 dB SNR
16-Bit 100 kHz Output from FIR Filter
12-Bit 400 kHz Output from Comb Filter
No Missing Codes
<0.001 dB In-Band Ripple

APPLICATIONS
Digital Audio Disk/Tape
Voice Bandwidth Communications
ADC Support for ADSP-21XX
High Accuracy Measurement Systems

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD776 is a 16-bit sigma-delta oversampled ADC, incorporating a 1-bit third-order modulator and digital decimation filter. An on-chip voltage reference circuit is also included.

The AD776 does not generally require the use of sample-hold circuits or complex antialiasing filters as a result of its sigma-delta architecture. The output is available both before and after the final Finite Impulse Response (FIR) decimation filter. This provides the flexibility of optimizing conversion speed or dynamic range: 12-bit/400 kHz (from the comb filter) or 16-bit/100 kHz (from the FIR filter). The serial port provides easy interface with a variety of standard processors including the ADSP-21XX.

The AD776 is specified for ac (or "dynamic") parameters such as SNR, THD and IMD which are important in signal processing and audio applications. Third order noise shaping is employed using 64 times oversampling to provide 90 dB SNR and −100 dB peak spurious component for signal bandwidths up to 45 kHz.

The AD776 operates from a single +5 V supply and typically consumes 350 mW during conversion. The device is packaged in 20-pin ceramic DIP (cerdip) and is offered in an industrial temperature grade (−40°C to +85°C).

PRODUCT HIGHLIGHTS

1. Analog Front End. The analog input is differential providing increased signal swing, increased power supply rejection ratio, and reduced sensitivity to clock jitter. Since the input signal is oversampled by a factor of 64, a complex antialiasing filter is not needed.
2. Flexible Digital Interface. The AD776 has three output pins for the serial interface: 1) serial data out (DOUT), 2) frame sync out (FSO), and 3) serial clock out (DOUT CLOCK). The serial port can interface with general purpose DSPs such as the ADSP-21XX, TMS320XX, and DSP56001/2 without additional "glue" logic.
3. Inherently Self-Sampling. The AD776 needs no external sample-and-hold amplifier to capture and freeze the analog input while the conversion takes place.
4. Speed/Performance Options. In addition to the standard 16-bit resolution at 100 kHz, the output of the comb filter can be accessed to provide 12-bit resolution at 400 kHz.

NOTES
[1]At +25°C.
[2]Analog Input = 1.2 V rms @ 10 kHz, $V_{COMMON\ MODE}$ = 2.5 V, CLKIN = 6.4 MHz.
[3]THD performance can be improved, depending upon the application, by making slight adjustments to the dc common mode voltage at the analog inputs.
[4]IMD measured at f_s = 48 kHz and using 61.6 Hz and 986.4 Hz as the input tones (sum of the two peaks added to be −3 dB FS).
[5]Applied differentially between AIN+ and AIN−.
[6]The input signal may be centered at any choice of dc offset voltage as long as peak values are bounded by the Maximum Analog Input Range value. Performance may be improved by reducing the maximum input signal by 3 dB. For nominal operation, 2.5 V dc offset is recommended.
[7]The AD776 may be operated from a single +5 V supply.
[8]AV_{DD}, DV_{DD} = 5.5 V; f = 12.8 MHz; T_A = +85°C.
[9]With external voltage reference.

Specifications subject to change without notice.

TIMING CHARACTERISTICS (AV_{DD}, DV_{DD} = +5 V ± 10%, T_{MIN} to T_{MAX}) — see Figures 14 through 18.

ABSOLUTE MAXIMUM RATINGS*

AV_{DD} to AGND . . . . . −0.3 V to +7.0 V
DV_{DD} to DGND . . . . . −0.3 V to +7.0 V
AGND to DGND . . . . . ±0.3 V
Digital Inputs to DGND . . . . . −0.3 V to DV_{DD}
Analog Inputs to AGND . . . . . −0.3 V to AV_{DD}
REFIN to AGND . . . . . −0.3 V to +2.5 V
Soldering (10 sec) . . . . . +300°C
Storage Temperature . . . . . −55°C to +150°C

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

The AD776 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD776 has been classified as a Category 1 Device.

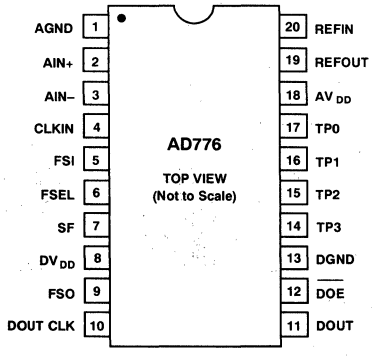
Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment, and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam discharged to the destination socket before devices are removed. For further information on ESD precaution, refer to Analog Devices' *ESD Prevention Manual.*

AD776 PIN DESCRIPTION

Symbol	Pin Number	Type	Name and Function
AGND	1		Analog Ground. Return current for analog front end. No internal connection to DGND.
AIN+	2	I	Analog Signal Input. Noninverting terminal.
AIN−	3	I	Analog Signal Input. Inverting terminal.
CLKIN	4	I	Clock In. This TTL compatible input accepts clock frequencies in the range of 1.0 MHz—12.8 MHz, with the output sample rate of the AD776 equal to CLKIN divided by 128 in FIR filter mode and 32 in comb filter mode.
FSI	5	I	Frame Sync Input. FSI is an optional control pin used to synchronize internal circuits and to start or reset the serial output data. If FSI is grounded, frame syncs will be automatically generated internally. When FSI is brought HIGH, serial data is presented at the output (DOUT—Pin 11). The purpose of FSI is to control externally the phasing of the A/D conversion process. FSI should be a periodic signal occurring every 16 DOUT CLK clock cycles in the 12-bit/400 kHz mode and every 32 DOUT CLK clock cycles in the 16-bit/ 100 kHz mode. When utilized, FSI must be synchronized to CLKIN as defined in the timing specification (see Figure 17). FSI allows multiple AD776s to be synchronized using a common frame sync source, requiring a common CLKIN signal.
FSEL	6	I	Filter Select. FSEL = "0" selects FIR output. FSEL = "1" selects comb filter output.
SF	7	I	Serial Format. Selects output format of DOUT and FSO when FSEL = "0." See Figures 14b and 15b.
DV_{DD}	8		+5 V ±10%. Digital Power Supply.
FSO	9	O	Frame Sync Output. Indicates beginning of serial data transmission on DOUT. See Timing Diagrams.
DOUT CLK	10	O	Serial Data Clock. See Figures 14a and 14b. In the FIR filter output mode (FSEL = 0), DOUT CLK is CLKIN divided by four; in the comb filter output mode (FSEL = 1), DOUT CLK is CLKIN divided by two.
DOUT	11	O	Data Output. Serial data is transmitted MSB first, twos complement format, once per FSO cycle with the data synchronous with DOUT CLK.
$\overline{DOE}$	12	I	Data Output Enable. Serial data (Pin 11) is an active output when $\overline{DOE}$ = "0." Serial data is three stated when $\overline{DOE}$ = "1."
DGND	13		Digital Ground. Return current for digital circuitry and pad drivers.
TP3, TP2, TP1, TP0	14, 15, 16, 17		Test Points. These pins must be connected to DGND.
AV_{DD}	18		+5 V ±10%. Analog Power Supply.
REFOUT	19	O	Internal Reference Output. Nominally +2 V with AV_{DD} = +5.0 V.
REFIN	20	I	Reference Input. +2 V maximum.

I = Input
O = Output

PIN CONFIGURATION



ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option*
AD776AQ	−40°C to +85°C	20-Pin Cerdip	Q-20

*For outline information see Package Information section.

TOTAL HARMONIC DISTORTION
Total Harmonic Distortion (THD) is the ratio of the rms sum of the harmonic components to the rms value of a full-scale input signal and is expressed in percent (%) or decibels (dB).

SIGNAL-TO-NOISE RATIO (SNR)
Signal-to-Noise Ratio (SNR) is defined to be the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the passband.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa± nfb, where m, n = 0, 1, 2, 3. . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa+fb) and (fa−fb), and the third order terms are (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude and the IMD products are normalized to a 0 dB input signal.

DIFFERENTIAL NONLINEARITY (DNL)
In an ideal ADC, code transitions are one LSB apart. Differential nonlinearity is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

INTEGRAL NONLINEARITY (INL)
The ideal transfer function for an ADC is a straight line drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the most negative code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the most positive code transition. INL is the worst-case deviation of a code center average from the straight line.

GAIN ERROR
The last transition should ideally occur at an analog value 1.5 LSB below the nominal full scale. The gain error is the deviation of the actual difference between the first and last code transition from the ideal difference between the first and last code transition.

MIDSCALE ERROR
Midscale error is the difference between the ideal midscale analog input voltage and the actual voltage producing the midscale output code.

PASSBAND
The passband is the region of the frequency spectrum unaffected by the attenuation of the decimation filter. In the case of the AD776, the passband is a function of the CLKIN frequency (see Table I).

PASSBAND RIPPLE
Passband ripple is defined as the variation in the amplitude response of the converter for input signal frequencies within the passband.

STOPBAND
The stopband is the region of the frequency spectrum in which the amplitude response is fully attenuated by the digital filter. In the case of the AD776, the stopband is a function of the CLKIN frequency (see Table I).

STOPBAND ATTENUATION
Stopband attenuation is defined to be the amount by which spectral components in the stopband are attenuated by the digital filter relative to the full-scale input range of the converter.

POWER SUPPLY REJECTION
DC variations in the power supply voltage will affect the midscale transition point, resulting in offset error. Power supply rejection is the maximum change in the midscale transition point due to a change in power-supply voltage from the nominal value. Additionally, there is another power supply variation to consider. AC ripple on the power supplies can couple noise into the ADC, resulting in degradation of dynamic performance.

GENERAL OVERVIEW
The AD776 is a single supply (+5 V) ADC providing simple analog and digital interface requirements. A minimal number of external connections are required to achieve the specified performance:

1. POWER
2. GROUNDS
3. CLOCKING
4. INPUT BUFFER CIRCUIT

These points will be further explored in the Application Information section.

THEORY OF OPERATION
The AD776 differs from traditional multi-bit ADCs through its use of sigma-delta conversion architecture. A 1-bit analog-to-digital conversion is performed at a very high rate, which redistributes quantization noise to beyond the frequency band of interest (see Figure 1). The frequency band of interest is denoted by f_C, and f_S is the sample frequency; $f_S/2$ is the expanded noise spectrum resulting from oversampling. The total noise energy remains constant, but by spreading it over a wider spectrum, the amount in the frequency band of interest is reduced. Noise shaping, performed by the modulator, attenuates noise in the signal passband and pushes out the noise energy into the higher frequency range (Figure 2). The oversampled signal is presented to the digital filter circuitry for:
- sophisticated averaging (filtering).
- removing high frequency noise (quantization noise removal).
- reducing sampling rate (decimation).

The resulting output data stream is presented in a format equivalent to a traditional ADC at a much reduced output sample rate.

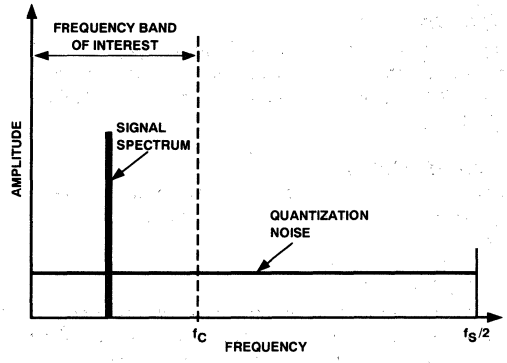


Figure 1. Noise Spectrum from Oversampling

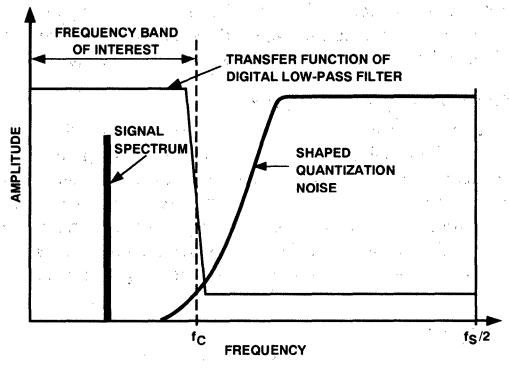

Figure 2. Noise Shaping

Figure 3 provides a block diagram of the various sections of the AD776. The Analog Front End is comprised of three differential switched-capacitor linear integrators which perform the noise-shaping function. Digital filter complexity of the AD776 is reduced by performing the filtering and decimation in two stages. The first section contains a 16:1 decimating comb filter stage with the output presented to a 4:1 decimating low-pass/compensation FIR filter, resulting in a final decimation ratio of 64:1. The decimation function is described in detail in the DECIMATION paragraph. The output data is presented in twos complement, MSB first serial data format, providing serial communication to a host processor.

This interface uses three dedicated pins: serial data output (DOUT), frame sync output (FSO), and serial clock output (DOUT CLK). The serial interface format of operation is pin selectable. The timing diagrams for the serial interface are described in the **DIGITAL TIMING** section.

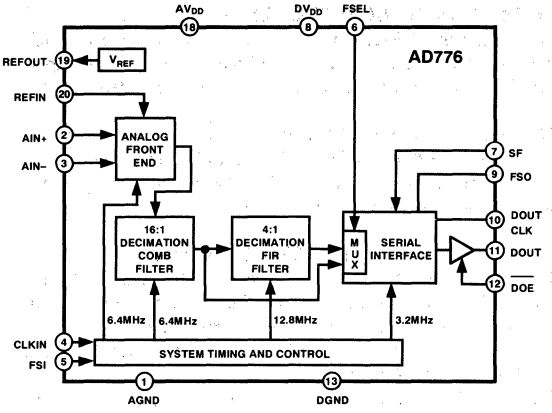

Figure 3. Block Diagram

ANALOG FRONT-END

The integrators of the third-order modulator front-end form a differential switched-capacitor network which results in increased signal swing, increased power supply rejection, and reduced sensitivity to clock jitter. Due to the nature of switched-capacitor circuits, the input impedance of AIN+, AIN−, and REFIN will vary with clock frequency. More information about these inputs is given in Table II and Table III.

The AD776 modulator is a third-order noise shaper which reduces quantization noise in the passband to the 16-bit level. The input signal is sampled at the rate of CLKIN/4. Since the input signal is oversampled by a factor of 64, a complex anti-aliasing filter is not needed; a single-pole RC filter will generally be sufficient. High quality polystyrene or NPO ceramic capacitors should be used for this filter.

DIGITAL FILTER OVERVIEW

The digital filters of the AD776 have two functions: high performance low-pass filtering and digital decimation. The shaped quantization noise from the output of the modulator is low-pass filtered to reduce the out-of-band noise components to a level which will not alias into the passband during the decimation process. Decimation then reduces the data rate to a manageable level.

DECIMATION

The comb filter performs the first-stage filtering of the analog front-end's quantized and noise-shaped output and decimates the input sample rate by a factor of 16:1. The z-domain transfer function for the comb filter is expressed by

$$H(z) = \frac{(1 - z^{-16})^4}{(1 - z^{-1})^4}$$

The frequency domain equivalent transfer function is

$$H(f) = \left[\frac{1}{16}\,\frac{sin\,(16\,\pi\,fT)}{sin\,(\pi\,fT)}\right]^4$$

where $T = 1/f_S$

f_S = the input sample rate for the Analog Front End (maximum 6.4 MHz).

The attenuation characteristics of the comb filter are shown in Figure 4. As illustrated, the frequency response in the passband region exhibits a nonflat behavior. In the 400 kHz mode, the output of the comb filter provides conversion data. The dynamic range is equivalent to approximately 72 dB, or 12 bits, in this mode. In the 16-bit/100 kHz mode, the comb filter serves as the input to the FIR filter. The FIR filter compensates for the passband roll-off of the comb filter and provides the final sharp cutoff required for stopband attenuation, removing the out-of-band noise components while partially serving as the system antialiasing filter.

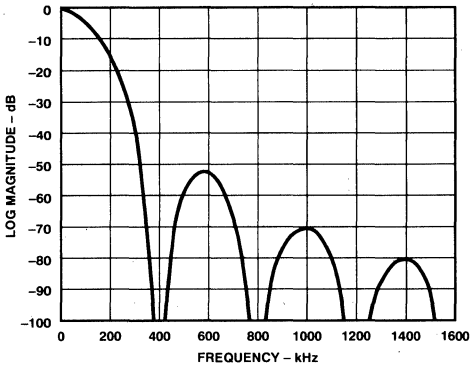

Figure 4. Comb Filter Response

Figure 5 illustrates the low-pass response of the FIR filter and Figure 6 shows the compensation function of the filter. The 255-tap FIR filter is low-pass with 9% transition-band, and with a CLKIN frequency of 12.8 MHz has a 45.5 kHz passband cutoff frequency, 50 kHz stopband frequency, 0.001 dB passband ripple, and a stopband ripple of −96 dB.

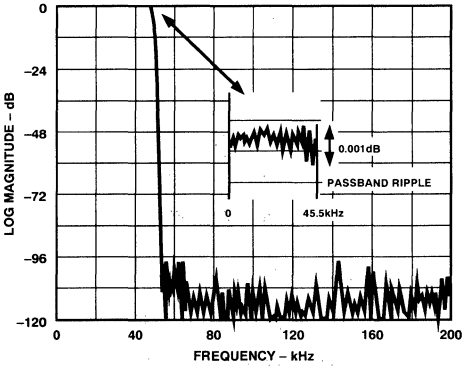

Figure 5. FIR Filter, Low-Pass Response

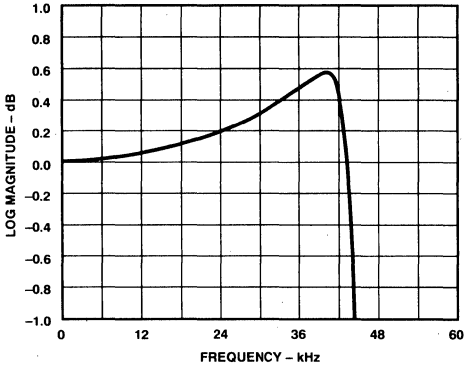

Figure 6. FIR Filter, Compensation Function

The passband and stopband frequencies of both the comb and FIR filters scale linearly with the CLKIN frequency, as shown in Table I.

Table I. FIR and Comb Filter Characteristics

CLKIN (MHz)	Passband (kHz)	Stopband (kHz)
12.8	45.5	50
12.288	43.7	48
11.2896	40.1	44.1
10.0	35.5	39.1
6.4	24.6	27.1

ANALOG INPUT

The input to the AD776, as previously described in the discussion of the analog front end, uses a switched-capacitor structure. As a result, the input impedance of AIN+ and AIN− will vary with clock frequency. Table II gives the typical analog input impedance for some common CLKIN frequencies. The input impedance is equal to $\approx 10^{12}/3f_{CLKIN}$, where f_{CLKIN} is the input clock rate.

Table II. Analog Input Impedance

Input Clock Rate (MHz)	Output Sample Rate (kHz) (FIR Filter Mode)	Analog Input Impedance (kΩ)
12.8	100	26
6.4	50	52
6.144	48	54.3
5.6448	44.1	59

The AD776 is designed to accept input signals of $(2 \times V_{REF}) - 0.5$ V which can be centered at various dc offsets (common-mode inputs) as long as the signal peaks are bounded by +4.0 V and 0 V. Signal peaks outside this range will result in signal clipping and increased distortion products.

Capacitive coupling between the CLKIN and AIN pins can cause degradation to dynamic performance. Special care should be taken with respect to the layout of the clock and analog inputs.

In consideration of the dynamic characteristics of the analog input, an external op amp is generally required to provide a low impedance drive. Care should be taken with op amp selection; even with modest loading conditions, most available op amps do not meet the low distortion requirements necessary to match the performance capabilities of the AD776. The AD712 op amp is a good choice for low noise and low distortion.

SINGLE-ENDED INPUT CONFIGURATIONS

The differential input of the AD776 provides a choice of several different input connections. Figure 7 shows a simple configuration for a single-ended input. AIN− is nominally biased at +2.5 V by resistively dividing the +5 V power supply (AV_{DD}). Since the analog input impedance is a function of the input clock rate, determination of bias resistor values to achieve a particular bias voltage will vary with clock rate and AV_{DD}.

The circuit shown in Figure 7 is a low cost, minimal component solution, but may suffer from poor power supply rejection as noise present on the power supply could be coupled directly into the AIN− pin. An improved input circuit is shown in Figure 8, where the offset voltage is derived from the AD680 voltage reference. The AD680 has 40 μV/V line regulation which results in only a 20 μV error due to 10% supply fluctuation. This improves power supply rejection of AIN− input to approximately 88 dB.

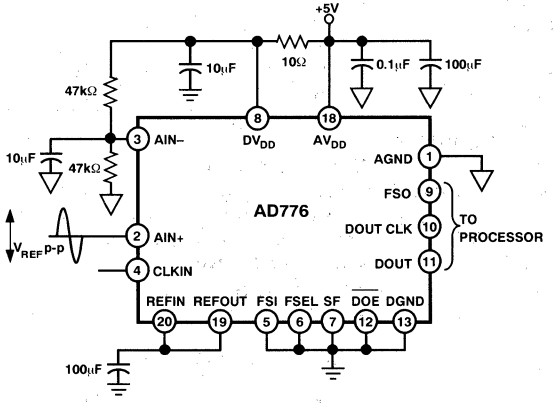

Figure 7. Simple Single-Ended Input Circuit

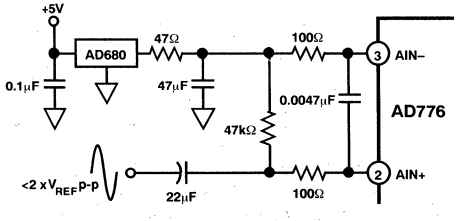

Figure 8. Single-Ended Input Circuit for Improved PSRR

For optimal performance in single-ended input applications, the circuit in Figure 9 may be used to convert the input to a differential signal.

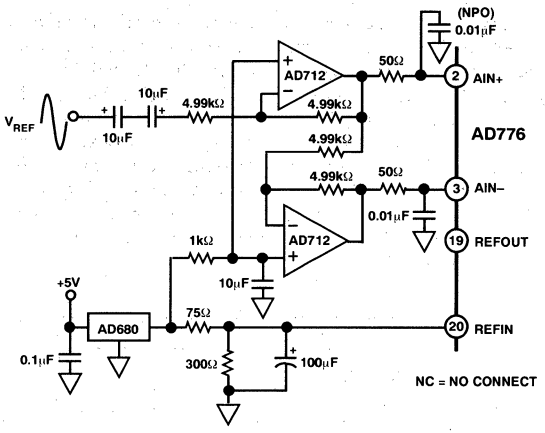

Figure 9. Single-Ended Input to Differential Circuit

REFERENCE INPUT

The AD776 has an on-chip 0.4 V_{DD} reference voltage circuit which can be used to drive REFIN, as shown in Figure 10. Alternately, an external voltage reference may be used to supply the required 2 V. REFIN exhibits characteristics similar to the Analog Input in that the input impedance is a function of the clock rate. This is illustrated in Table III. The minimum reference impedance is equal to $10^{12}/2.5\ f_{CLK}$, where f_{CLK} is the input clock rate.

Table III. Reference Input Impedance

Input Clock Rate (MHz)	Output Sample Rate (kHz)	Reference Input Impedance (kΩ min)
12.8	100	31.3
6.4	50	62.5
6.144	48	65.1
5.6448	44.1	70.9

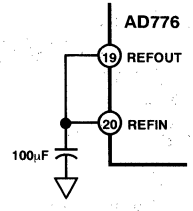

Figure 10. Simple Reference Voltage Circuit

While the internal reference will be adequate for most applications, power supply rejection and overall regulation may be improved through the use of an external reference. The process of selecting an external voltage reference should include consideration of drive capability, initial error, noise, and drift characteristics. A suitable choice would be the AD680 as shown in Figure 11.

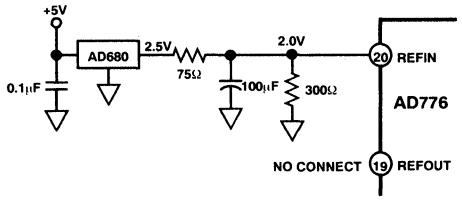

Figure 11. External Voltage Reference Circuit

MULTIPLEXING

The AD776 can also be used with an input multiplexer when the comb filter output is selected by setting FSEL = 1. If f_{CLK} = 12.8 MHz, the minimum multiplex intervals are (including the time to shift the data out from the serial interface):

15 μs (if the FSI and mux are perfectly synchronized)
17.5 μs (if the FSI and mux are not synchronized).

CLOCK GENERATION

With sigma-delta converters, it is critical that clock jitter be minimized in order to achieve optimal performance. Figure 12 illustrates a simple circuit used to derive a clock source for the AD776. An alternative would be to use an oscillator such as the CK1100 series from Cardinal Components (Montclair, NJ) or the F1100 from Fox Electronics. Compared with performance obtained with a typical crystal, use of an oscillator improves SNR by approximately 4 dB.

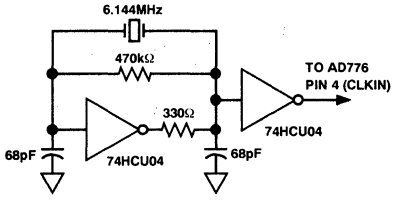

Figure 12. Basic Clock Circuit

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. A 1.22 mA current through a 0.5 Ω trace will develop a voltage drop of 0.6 mV, which is 20 LSBs at the 16 bit level for a 2 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals.

Analog and digital signals should not share a common return path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point at (or under) the part to minimize ground loops. This is preferred to interconnecting the grounds at the supplies.

Analog signals should be routed as far as possible from digital signals and should cross them, if at all, only at right angles. The AD776 may be treated as an analog component, with both AGND and DGND connected to a single analog ground plane. This helps to isolate the AD776 from large digital ground currents. For these reasons, the use of wire wrap circuit construction will not provide adequate performance; careful printed circuit board construction is preferred.

POWER SUPPLIES AND DECOUPLING

With high performance linear circuits, changes in the power supplies can produce undesired changes in the performance of the circuit. Optimally, well regulated power supplies with less than 1% ripple should be selected. The ac output impedance of a power supply is a complex function of frequency, but in general will increase with frequency. High frequency switching such as that encountered with digital circuitry requires fast transient currents which most power supplies cannot adequately provide. This results in voltage spikes on the supplies. To compensate for the finite ac output impedance of the supplies, it is necessary to store "reserves" of charge in bypass capacitors. These capacitors can effectively lower the ac impedance presented to the AD776 power inputs which in turn will significantly reduce the magnitude of the voltage spikes. Decoupling capacitors, typically 0.1 μF, should be placed as close as possible to each power supply pin of the AD776. It is essential that these capacitors be placed physically close to the AD776 to minimize the inductance of the PCB trace between the capacitor and the supply pin.

Additionally, it is beneficial to have large capacitors (>47 μF) located at the point where the power connects to the PCB with 10 μF capacitors located in the vicinity of the ADC to further reduce low frequency ripple.

The AD776 may be operated from a single +5 V supply. However, performance is optimized by using separate analog (AV_{DD}) and digital (DV_{DD}) supplies. Separate supplies enable isolation of digital noise from the analog circuitry. When separate supplies are used, AV_{DD} should be decoupled to analog ground (AGND) and DV_{DD} should be decoupled to digital ground (DGND) with decoupling capacitors.

When a single +5 V supply is used, the circuit shown in Figure 13 provides adequate decoupling.

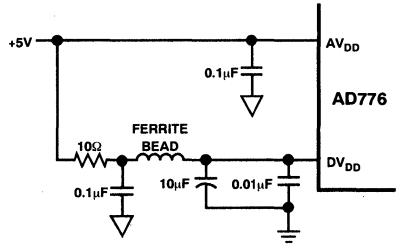

Figure 13. Single Supply Decoupling

DIGITAL TIMING

The CLKIN frequency and the choice of output filter mode (FIR or Comb) determine the output sample rate of the AD776. With FSEL LOW, the FIR filter output is selected and the output rate is equal to CLKIN divided by 128. When FSEL is HIGH, the Comb filter is selected and the output sample rate is equal to CLKIN divided by 32. The input sample rate (or modulator frequency) is always the CLKIN frequency divided by 2.

The flexible serial data output interface of the AD776 may be configured in one of three modes. MODE A and MODE B are used when the FIR filter output is desired. MODE C should be selected when output from the comb filter is used. Output data is always transmitted as 16-bit, twos complement, MSB first, serial words. In all modes, the FSI pin may be asserted to reset the serial data output and synchronize internal circuits. A $\overline{DOE}$ pin is available to place the DOUT pin in a high impedance state.

Configuring the appropriate timing mode is controlled by the FSEL and SF pins. The truth table is shown in Table IV.

Table IV. Timing Mode Truth Table

FSEL	SF	Output Mode
0	0	A
0	1	B
1	0	C

MODE A

The timing diagrams for MODE A are shown in Figures 14a and 14b. If MODE A is selected, an internal multiplexer routes serial data from the output of the FIR filter to the DOUT pin. The output sample rate is a function of the clock present at the CLKIN pin where:

$$Output\ Sample\ Rate = CLKIN/128$$

A continuous serial output clock, DOUT CLK, is available with the bit rate determined by:

$$DOUT\ CLK = CLKIN/4.$$

Serial data from the DOUT pin is valid on the falling edges of DOUT CLK. A framing signal, FSO, occurs with a period equal to the output sample rate (Figure 14b). The FSO signal is HIGH during the falling edge of DOUT CLK prior to the beginning of a new output data word.

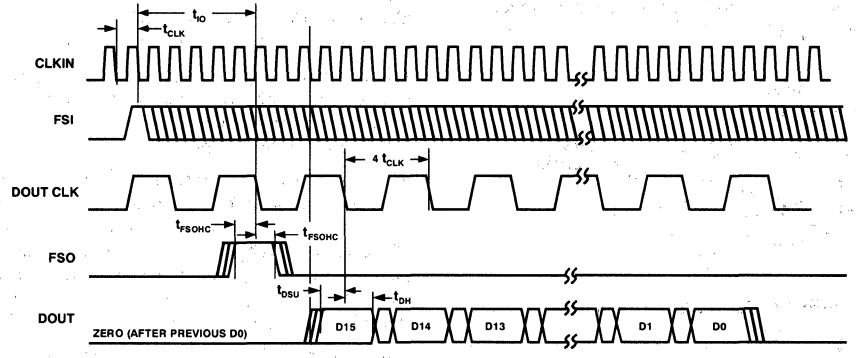

Figure 14a. Mode A Timing

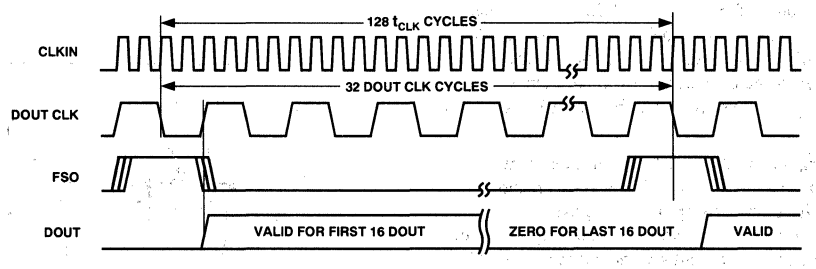

Figure 14b. Mode A Timing

MODE B

The timing diagrams for MODE B are shown in Figures 15a and 15b. If Mode B is selected, the internal multiplexer routes serial data from the output of the FIR filter to the DOUT pin similar to MODE A. The output sample rate is a function of the clock present at the CLKIN pin where:

Output Sample Rate = *CLKIN*/128.

A continuous serial output clock, DOUT CLK, is available with the bit rate determined by:

DOUT CLK = *CLKIN*/4.

Note that serial data present at the DOUT pin is valid on the rising edges of DOUT CLK. The framing signal, FSO, occurs with a period equal to the output sample rate. In MODE B, the FSO signal goes LOW at the beginning of the output data word and remains LOW until the entire word is transmitted.

2

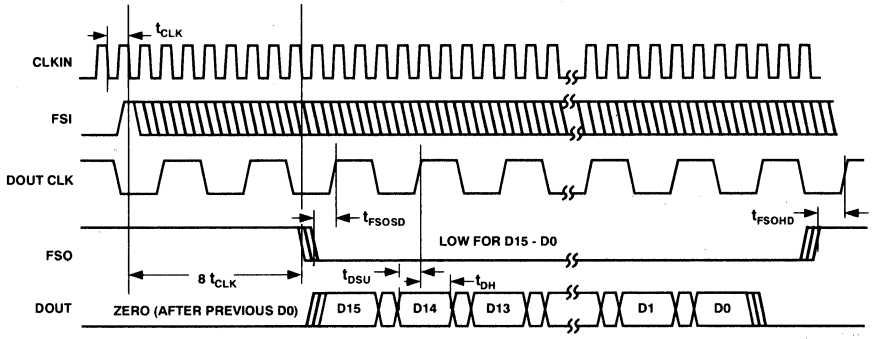

Figure 15a. Mode B Timing

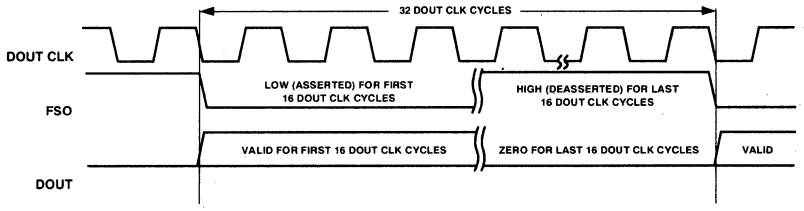

Figure 15b. Mode B Timing

MODE C

The timing diagrams for MODE C are shown in Figure 16. If Mode C is selected, the internal multiplexer routes serial data from the output of the COMB filter to the DOUT pin, bypassing the FIR filter. The output sample rate is a function of the clock present at the CLKIN pin where:

Output Sample Rate = *CLKIN*/32.

A continuous serial output clock, DOUT CLK, is available with the bit rate determined by:

DOUT CLK = *CLKIN*/2.

Serial output data is valid on the falling edges of DOUT CLK. The framing signal, FSO, occurs with a period equal to the output sample rate. The FSO signal is HIGH during the falling edge of DOUT CLK prior to transmission of the next output data word. Note that in MODE C, this is also when the LSB, (D0), of the previous data word is valid.

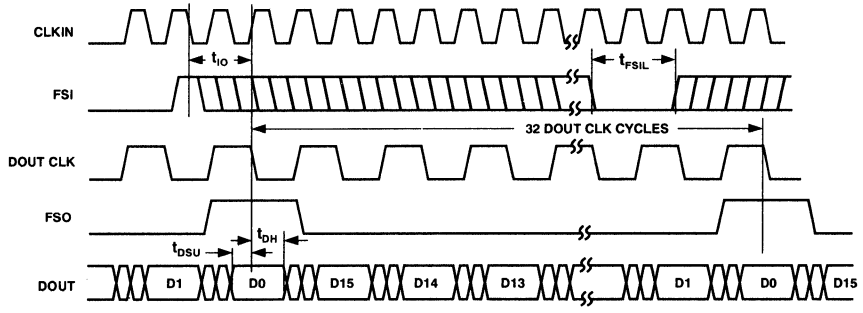

Figure 16. Mode C Timing

FSI Operation

A frame sync input is available to the user on the FSI pin to reset the serial data output and synchronize internal circuits.

Referring to Figure 17, the FSI pin is sampled on the falling edge of CLKIN. The FSI pin must adhere to several conditions depending on which mode is being used as follows:

FSI in MODE A, MODE B

1. FSI should be a periodic signal occurring every 32 DOUT CLK periods.
2. FSI must be deasserted for at least 2 CLKIN periods prior to being asserted.
3. FSI must be synchronized to CLKIN to meet the timing requirements outlined in Figure 17.

FSI in MODE C

1. FSI should be a periodic signal occurring every 16 DOUT CLK periods.
2. FSI must be deasserted for at least 2 CLKIN periods prior to being asserted.
3. FSI must be synchronized to CLKIN to meet the timing requirements outlined in Figure 17.

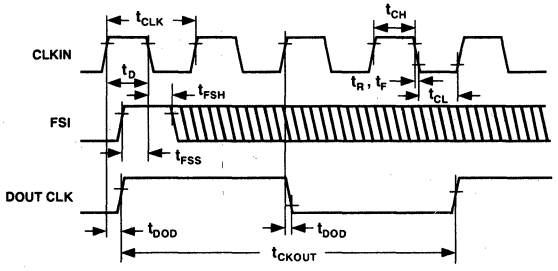

Figure 17. Frame Sync Input (FSI) Timing (FIR Filter Output Mode)

Synchronizing Two Channels

The FSI pin is useful when multiple AD776s are used together and must be synchronized. In such a case, a single pulse may be applied to FSI inputs of the converters. This causes the internal "state-machine" of the AD776 to be reset. Thus, the internal clocking for both the analog and digital circuitry of each individual converter is synchronized and in-phase. In the case of a single FSI pulse, it must still adhere to the timing outlined in Figure 17.

Three-Stating the DOUT Pin ($\overline{DOE}$)

In all modes DOUT may be three-stated using the $\overline{DOE}$ pin. Operation of the $\overline{DOE}$ input is shown in Figure 18. When the $\overline{DOE}$ input is HIGH, serial data will be present and active at the DOUT pin. When $\overline{DOE}$ is brought LOW, the DOUT pin is placed in a high-impedance state. $\overline{DOE}$ is completely asynchronous and independent of input and output clocks. DOUT loading will affect actual performance.

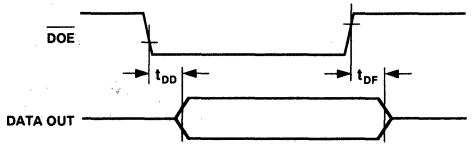

Figure 18. Data Output Timing

INTERFACING THE AD776

The AD776 is designed for ease of interface with a variety of popular processors. The following diagrams illustrate typical configurations:

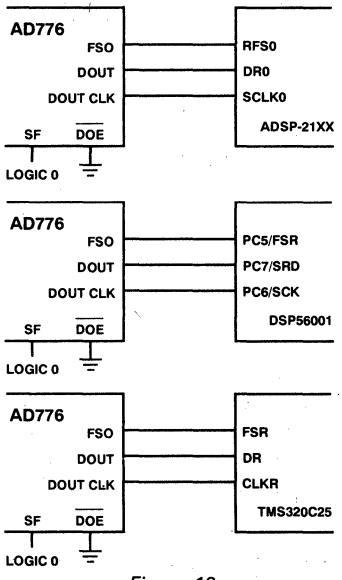

Figure 19.

ANALOG DEVICES

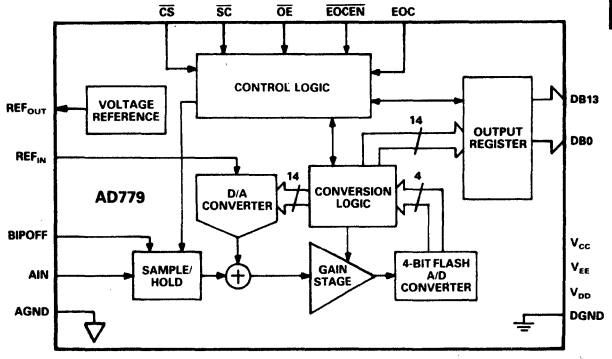
14-Bit 128 kSPS Complete Sampling ADC

AD779*

FEATURES

AC and DC Characterized and Specified (K, B, T Grades)
128k Conversions per Second
1 MHz Full Power Bandwidth
500 kHz Full Linear Bandwidth
80 dB S/N+D (K, B, T Grades)
Twos Complement Data Format (Bipolar Mode)
Straight Binary Data Format (Unipolar Mode)
10 MΩ Input Impedance
16-Bit Bus Interface (See AD679 for 8-Bit Interface)
On-Board Reference and Clock
10 V Unipolar or Bipolar Input Range
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD779 is a complete, multipurpose 14-bit monolithic analog-to-digital converter, consisting of a sample-hold amplifier (SHA), a microprocessor compatible bus interface, a voltage reference and clock generation circuitry.

The AD779 is specified for ac (or "dynamic") parameters such as S/N+D ratio, THD and IMD which are important in signal processing applications. In addition, the AD779K, B and T grades are fully specified for dc parameters which are important in measurement applications.

The 14 data bits are accessed by a 16-bit bus in a single read operation. Data format is straight binary for unipolar mode and twos complement binary for bipolar mode. The input has a full-scale range of 10 V with a full power bandwidth of 1 MHz and a full linear bandwidth of 500 kHz. High input impedance (10 MΩ) allows direct connection to unbuffered sources without signal degradation.

This product is fabricated on Analog Devices' BiMOS process, combining low power CMOS logic with high precision, low noise bipolar circuits; laser-trimmed thin-film resistors provide high accuracy. The converter utilizes a recursive subranging algorithm which includes error correction and flash converter circuitry to achieve high speed and resolution.

The AD779 operates from +5 V and ±12 V supplies and dissipates 560 mW (typ). Twenty-eight-pin plastic DIP and ceramic DIP packages are available.

PRODUCT HIGHLIGHTS

1. COMPLETE INTEGRATION: The AD779 minimizes external component requirements by combining a high speed sample-hold amplifier (SHA), ADC, 5 V reference, clock and digital interface on a single chip. This provides a fully specified sampling A/D function unattainable with discrete designs.
2. SPECIFICATIONS: The AD779K, B and T grades provide fully specified and tested ac and dc parameters. The AD779J, A and S grades are specified and tested for ac parameters; dc accuracy specifications are shown as typicals. DC specifications (such as INL, gain and offset) are important in control and measurement applications. AC specifications (such as S/N+D ratio, THD and IMD) are of value in signal processing applications.
3. EASE OF USE: The pinout is designed for easy board layout, and the single cycle read output provides compatibility with 16-bit buses. Factory trimming eliminates the need for calibration modes or external trimming to achieve rated performance.
4. RELIABILITY: The AD779 utilizes Analog Devices' monolithic BiMOS technology. This ensures long term reliability compared to multichip and hybrid designs.
5. The AD779 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD779/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]The AD779 is not designed to operate from ±15 V supplies.

ESD SENSITIVITY

The AD779 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD779 has been classified as a Category 1 device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual.*

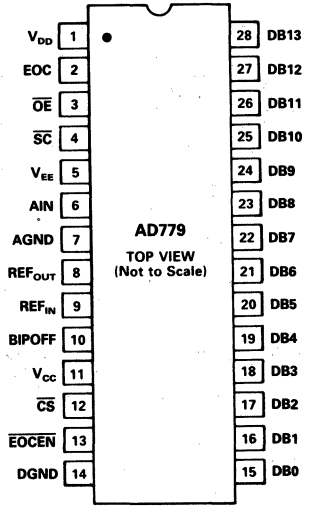
AD779 PIN DESCRIPTION

Symbol	28-Pin DIP Pin No.	44-Lead JLCC Pin No.	Type	Name and Function
AGND	7	11	P	Analog Ground. This is the ground return for AIN only.
AIN	6	10	AI	Analog Signal Input.
BIPOFF	10	15	AI	Bipolar Offset. Connect to AGND for +10 V input unipolar mode and straight binary output coding. Connect to REF_{OUT} for ±5 V input bipolar mode and twos-complement binary output coding.
$\overline{CS}$	12	19	DI	Chip Select. Active LOW.
DGND	14	23	P	Digital Ground
DB13–DB0	28–15	43, 42, 40, 39, 37, 36, 35, 34, 33, 31, 30, 27, 26, 25	DO	Data Bits. These pins provide all 14 bits in one 14 bit parallel output. Active HIGH
EOC	2	3	DO	End-of-Convert. EOC goes LOW when a conversion starts and goes HIGH when the conversion is finished. EOC is a three-state output. See $\overline{EOCEN}$ pin for information on EOC gating.
$\overline{EOCEN}$	13	21	DI	End-of-Convert Enable. Enables EOC pin. Active LOW.
$\overline{OE}$	3	5	DI	Output Enable. A down-going transition on $\overline{OE}$ enables data bits. Active LOW.
REF_{IN}	9	14	AI	Reference Input. +5 V input gives 10 V full scale range.
REF_{OUT}	8	12	AO	+5 V Reference Output. Tied to REF_{IN} for normal operation.
$\overline{SC}$	4	6	DI	Start Convert. Active LOW.
V_{CC}	11	17	P	+12 V Analog Power.
V_{EE}	5	8	P	−12 V Analog Power.
V_{DD}	1	1	P	+5 V Digital Power.

Type: AI = Analog Input.
AO = Analog Output.
DI = Digital Input.
DO = Digital Output. All DO pins are three-state drivers.
P = Power.

PIN CONFIGURATION

DIP Package



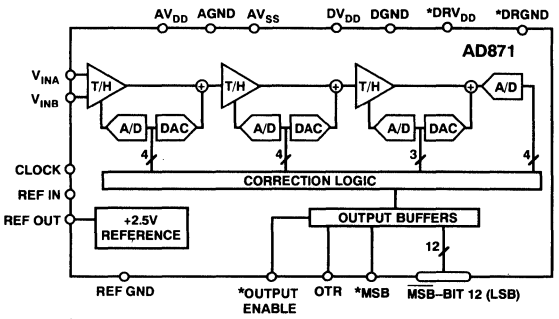
Complete 12-Bit 5 MSPS Monolithic A/D Converter

AD871

FEATURES

Monolithic 12-Bit 5 MSPS A/D Converter
Low Noise: 0.17 LSB RMS Referred to Input
No Missing Codes Guaranteed
Differential Nonlinearity Error: 0.5 LSB
Signal-to-Noise and Distortion Ratio: 68 dB
Spurious-Free Dynamic Range: 73 dB
Power Dissipation: 1.03 W
Complete: On-Chip Track-and-Hold Amplifier and Voltage Reference
Pin Compatible with the AD872
Twos Complement Binary Output Data
Out of Range Indicator
28-Pin Ceramic DIP or 44-Pin Surface Mount Package

FUNCTIONAL BLOCK DIAGRAM



*ONLY AVAILABLE ON 44-PIN SURFACE MOUNT PACKAGE.

PRODUCT DESCRIPTION

The AD871 is a monolithic 12-bit, 5 Msps analog to digital converter with an on-chip, high performance track-and-hold amplifier and voltage reference. The AD871 uses a multistage differential pipelined architecture with error correction logic to provide 12-bit accuracy at 5 Msps data rates and guarantees no missing codes over the full operating temperature range. The AD871 is a redesigned variation of the AD872 12-bit, 10 Msps ADC, optimized for lower noise in applications requiring sampling rates of 5 Msps or less. The AD871 is pin compatible with the AD872, allowing the parts to be used interchangeably as system requirements change.

The low-noise input track-and-hold (T/H) of the AD871 is ideally suited for high-end imaging applications. In addition, the T/H's high input impedance and fast settling characteristics allow the AD871 to easily interface with multiplexed systems that switch multiple signals through a single A/D converter. The dynamic performance of the input T/H also renders the AD871 suitable for sampling single channel inputs at frequencies up to and beyond the Nyquist rate. The AD871 provides both reference output and reference input pins, allowing the on-board reference to serve as a system reference. An external reference can also be chosen to suit the dc accuracy and temperature drift requirements of the application. A single clock input is used to control all internal conversion cycles. The digital output data is presented in twos complement binary output format. An out-of-range signal indicates an overflow condition, and can be used with the most significant bit to determine low or high overflow.

The AD871 is fabricated on Analog Devices ABCMOS-1 process which utilizes high speed bipolar and CMOS transistors on a single chip. High speed, precision analog circuits are now combined with high density logic circuits.

The AD871 is packaged in a 28-pin ceramic DIP and a 44-pin leadless ceramic surface mount package and is specified for operation from 0°C to +70°C and −55°C to +125°C.

PRODUCT HIGHLIGHTS

The AD871 offers a complete single-chip sampling 12-bit, 5 Msps analog-to-digital conversion function in a 28-pin DIP or 44-pin leadless ceramic surface mount package (LCC).

Low Noise—The AD871 features 0.17 LSB referred-to-input noise, producing essentially a "1 code wide" histogram for a code-centered dc input.

Low Power—The AD871 at 1.03 W consumes a fraction of the power of presently available hybrids.

On-Chip Track-and-Hold (T/H)—The low noise, high impedance T/H input eliminates the need for external buffers and can be configured for single ended or differential inputs.

Ease of Use—The AD871 is complete with T/H and voltage reference and is pin-compatible with the AD872 (12-bit, 10 Msps monolithic ADC).

Out of Range (OTR)—The OTR output bit indicates when the input signal is beyond the AD871's input range.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.
[2]LCC Package Only.

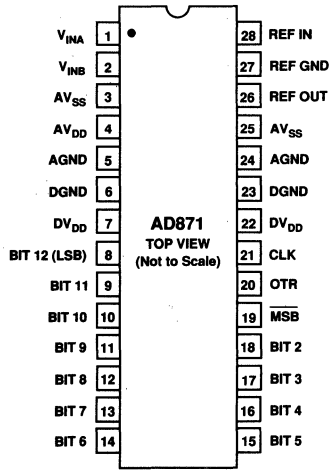
PIN DESCRIPTION

Symbol	DIP Pin No.	LCC Pin No.	Type	Name and Function
AGND	5, 24	9, 36	P	Analog Ground.
AV_{DD}	4	6, 38	P	+5 V Analog Supply.
AV_{SS}	3, 25	5, 40	P	−5 V Analog Supply.
$\overline{MSB}$	19	29	DO	Inverted Most Significant Bit. Provides twos complement output data format.
MSB	N/A	27	DO	Most Significant Bit.
BIT 2–BIT 11	18–9	26–17	DO	Data Bits 2 through 11.
BIT 12 (LSB)	8	16	DO	Least Significant Bit.
CLK	21	31	DI	Clock Input. The AD871 will initiate a conversion on the rising edge of the clock input. See the Timing Diagram for details.
DV_{DD}	7, 22	33	P	+5 V Digital Supply.
DGND	6, 23	10	P	Digital Ground.
DRV_{DD}	N/A	12, 32	P	+5 V Digital Supply for the output drivers.
DRGND	N/A	11, 34	P	Digital Ground for the output drivers. (See section on Power Supply Decoupling for details on DRV_{DD} and DRGND.)
OTR	20	30	DO	Out of Range is Active HIGH on the leading edge of code 0 or the trailing edge of code 4096. See Output Data Format Table III.
OEN	N/A	13	DI	Output Enable. See the Three State Output Timing Diagram for details.
REF GND	27	42	AI	Reference Ground.
REF IN	28	43	AI	Reference Input. +2.5 V input gives ±1 V full-scale range.
REF OUT	26	41	AO	+2.5 V Reference Output. Tie to REF IN for normal operation.
V_{INA}	1	1	AI	(+) Analog Input Signal on the differential input amplifier.
V_{INB}	2	2	AI	(−) Analog Input Signal on the differential input amplifier.
NC	N/A	3, 4, 7, 8, 14, 15, 28, 35, 37, 39, 44		No Connect.

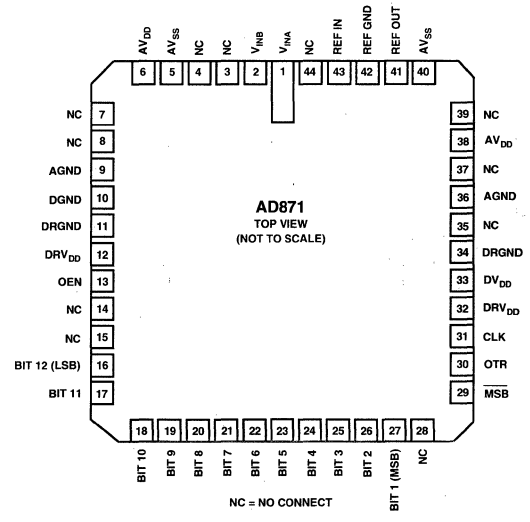
TYPE: AI = Analog Input; AO = Analog Output; DI = Digital Input; DO = Digital Output; P = Power; N/A = Not Available on 28-pin DIP. Only available on 44-pin surface mount package.

PIN CONFIGURATIONS

28-Pin Ceramic DIP



44-Pin LCC



DEFINITIONS OF SPECIFICATIONS

LINEARITY ERROR

Linearity error refers to the deviation of each individual code from a line drawn from "negative full scale" through "positive full scale." The point used as "negative full scale" occurs 1/2 LSB before the first code transition. "Positive full scale" is defined as a level 1 1/2 LSB beyond the last code transition. The deviation is measured from the middle of each particular code to the true straight line.

DIFFERENTIAL LINEARITY ERROR (DNL, NO MISSING CODES)

An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. Guaranteed no missing codes to 12-bit resolution indicates that all 4096 codes must be present over all operating ranges.

ZERO ERROR

The major carry transition should occur for an analog value 1/2 LSB below analog common. Zero error is defined as the deviation of the actual transition from that point. The zero error and temperature drift specify the initial deviation and maximum change in the zero error over temperature.

GAIN ERROR

The first code transition should occur for an analog value 1/2 LSB above nominal negative full scale. The last transition should occur for an analog value 1 1/2 LSB below the nominal positive full scale. Gain error is the deviation of the actual difference between first and last code transitions and the ideal difference between first and last code transitions.

TEMPERATURE DRIFT

The temperature drift for zero error and gain error specifies the maximum change from the initial (25°C) value to the value at T_{MIN} or T_{MAX}.

POWER SUPPLY REJECTION

The specifications show the maximum change in the converter's full-scale as the supplies are varied from nominal to min/max values.

APERTURE JITTER

Aperture jitter is the variation in aperture delay for successive samples and is manifested as noise on the input to the A/D.

APERTURE DELAY

Aperture delay is a measure of the Track-and-Hold Amplifier (THA) performance and is measured from the rising edge of the clock input to when the input signal is held for conversion.

OVERVOLTAGE RECOVERY TIME

Overvoltage recovery time is defined as that amount of time required for the ADC to achieve a specified accuracy after an overvoltage (50% greater than full-scale range), measured from the time the overvoltage signal reenters the converter's range.

DYNAMIC SPECIFICATIONS

SIGNAL-TO-NOISE AND DISTORTION (S/N+D) RATIO

S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

TOTAL HARMONIC DISTORTION (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

INTERMODULATION DISTORTION (IMD)

With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb), and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (2 fb − fa). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

FULL-POWER BANDWIDTH

The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

SPURIOUS FREE DYNAMIC RANGE

The difference, in dB, between the rms amplitude of the input signal and the peak spurious signal.

ORDERING GUIDE

Model	Temperature Range	Package Option[1, 2]
AD871JD	0°C to +70°C	D-28
AD871JE	0°C to +70°C	E-44A
AD871SD[3]	−55°C to +125°C	D-28
AD871SE[3]	−55°C to +125°C	E-44A

THEORY OF OPERATION

The AD871 is implemented using a 4-stage pipelined multiple flash architecture. A differential input track-and-hold amplifier (THA) acquires the input and converts the input voltage into a differential current. A 4-bit approximation of the input is made by the first flash converter, and an accurate analog representation of this 4-bit guess is generated by a digital-to-analog converter. This approximation is subtracted from the THA output to produce a remainder, or residue. This residue is then sampled and held by the second THA, and a 4-bit approximation is generated and subtracted by the second stage. Once the second THA goes into hold, the first stage goes back into track to acquire a new input signal. The third stage provides a 3-bit approximation/subtraction operation, and produces the final residue, which is passed to a final 4-bit flash converter. The 15 output bits from the 4 flash converters are accumulated in the correction logic block, which adds the bits together using the appropriate correction algorithm, to produce the 12-bit output word. The digital output, together with overrange indicator, is latched into an output buffer to drive the output pins.

The additional THA inserted in each stage of the AD871 architecture allows pipelining of the conversion. In essence, the converter is converting multiple inputs simultaneously, processing them through the converter chain serially. This means that while the converter is capable of capturing a new input sample every clock cycle, it actually takes three clock cycles for the conversion to be fully processed and appear at the output. This "pipeline delay" is often referred to as latency, and is not a concern in most applications, however there are some cases where it may be a consideration. For example, some applications call for the A/D converter to be placed in a high speed feedback loop, where its input is servoed to provide a desired result at the digital output (e.g., offset calibration or zero restoration in video applications). In these cases the 3 clock cycle delay through the pipeline must be accounted for in the loop stability calculations. Also, because the converter is working on three conversions simultaneously, major disruptions to the part (such as a large glitch on the supplies or reference) may corrupt three data samples. Finally, there will be a minimum clock rate below which the THA droop corrupts the signal in the pipeline. In the case of the AD871, this minimum clock rate is 10 kHz.

The high impedance differential inputs of the AD871 allow a variety of input configurations (see APPLYING THE AD871). The AD871 converts the voltage difference between the V_{INA} and V_{INB} pins. For single-ended applications, one input pin (V_{INA} or V_{INB}) may be grounded, but even in this case the differential input can provide a performance boost: for example, for an input coming from a coaxial cable, V_{INB} can be tied to the shield ground, allowing the AD871 to reject shield noise as common mode. The high input impedance of the device minimizes external driving requirements and allows the user to externally select the appropriate termination impedance for the application.

The AD871 clock circuitry uses both edges of the clock in its internal timing circuitry (see spec page for exact timing requirements.) The AD871 samples the analog input on the rising edge of the clock input. During the clock low time (between the falling edge and rising edge of the clock) the input THA is in track mode; during the clock high time it is in hold. System disturbances just prior to the rising edge of the clock may cause the part to acquire the wrong value, and should be minimized.

While the part uses both clock edges for its timing, jitter is only a significant issue for the rising edge of the clock (see CLOCK INPUT section).

APPLYING THE AD871

ANALOG INPUTS

The AD871 features a high impedance differential input that can readily operate on either single-ended or differential input signals. Table I summarizes the nominal input voltage span for both single-ended and differential modes, assuming a 2.5 V reference input.

Table I. Input Voltage Span

	V_{INA}	V_{INB}	V_{INA}–V_{INB}
Single-Ended	+1 V	GND	+1 V (Positive Full Scale)
	−1 V	GND	−1 V (Negative Full Scale)
Differential	+0.5 V	−0.5 V	+1 V (Positive Full Scale)
	−0.5 V	+0.5 V	−1 V (Negative Full Scale)

Figure 10 shows an approximate model for the analog input circuit. As this model indicates, when the input exceeds 1.6 V (with respect to AGND), the input device may saturate, causing the input impedance to drop substantially and significantly reducing the performance of the part. Input compliance in the negative direction is somewhat larger, showing virtually no degradation in performance for inputs as low as −1.9 V.

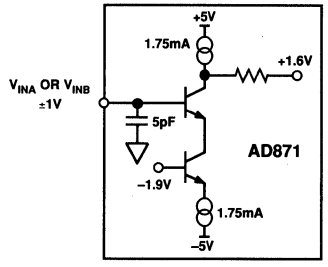

Figure 10. AD871 Equivalent Analog Input Circuit

Figure 11 illustrates the effect of varying the common-mode voltage of a −0.5 dB input signal on total harmonic distortion.

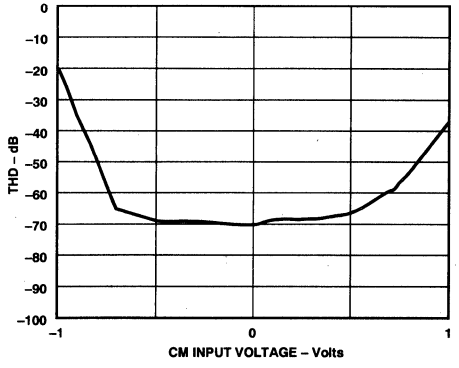

Figure 11. AD871 Total Harmonic Distortion vs. CM Input Voltage, f_{IN} = 1 MHz, FS = 5 MSPS

Figure 12 shows the common-mode rejection performance vs. frequency for a 1 V p-p common mode input. This excellent common-mode rejection over a wide bandwidth affords the user the opportunity to eliminate many potential sources of input noise as common mode by using the differential input structure of the AD871.

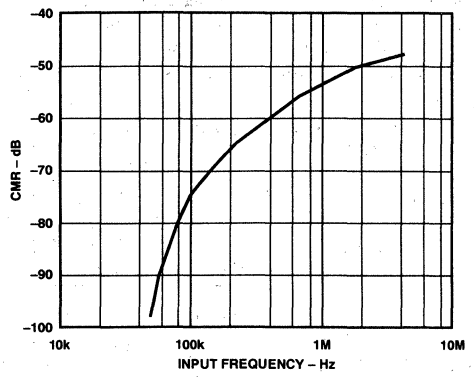

Figure 12. Common-Mode Rejection vs. Input Frequency, 1 V p-p Input

Figures 13 and 14 illustrate typical input connections for single-ended inputs.

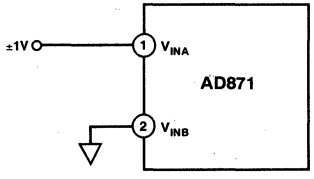

Figure 13. AD871 Single-Ended Input Connection

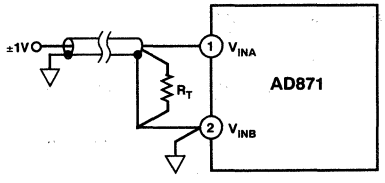

Figure 14. AD871 Single-Ended Input Connection Using a Shielded Cable

The cable shield is used as the ground connection for the V_{INB} input, providing the best possible rejection of the cable noise from the input signal. Note also that the high input impedance of the AD871 allows the user to select the termination impedance, be it 50 ohms, 75 ohms, or some other value. Furthermore, unlike many flash converters, most AD871 applications will not require an external buffer amplifier. If such an amplifier is required, we suggest either the AD811 or AD9617.

Figure 15 illustrates how external amplifiers may be used to convert a single-ended input into a differential signal. The resistor values of 536 Ω and 562 Ω were selected to provide optimum phase matching between U1 and U2.

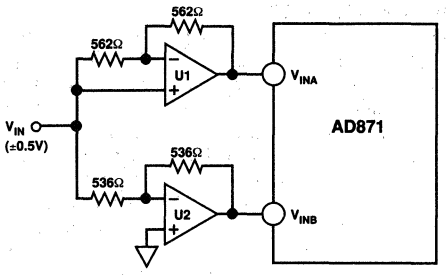

Figure 15. Single-Ended to Differential Connections; U1, U2 = AD811 or AD9617

The use of the differential input signal can help to minimize even-order distortion from the input THA where performance beyond −70 dB is desired.

Figure 16 shows the AD871 large signal (−0.5 dB) and small signal (−20 dB) frequency response.

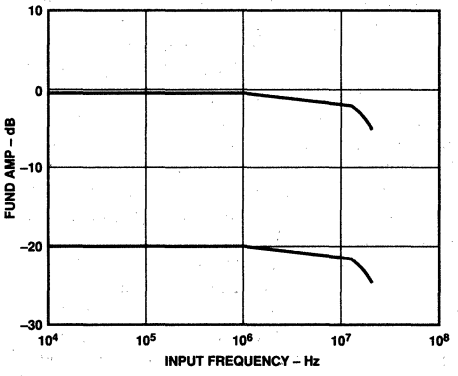

Figure 16. Full Power (−0.5 dB) and Small Signal Response (−20 dB) vs. Input Frequency

The AD871's wide input bandwidth facilitates rapid acquisition of transient input signals: the input THA can typically settle to 12-bit accuracy from a full-scale input step in less than 80 ns. Figure 17 illustrates the typical acquisition of a full-scale input step.

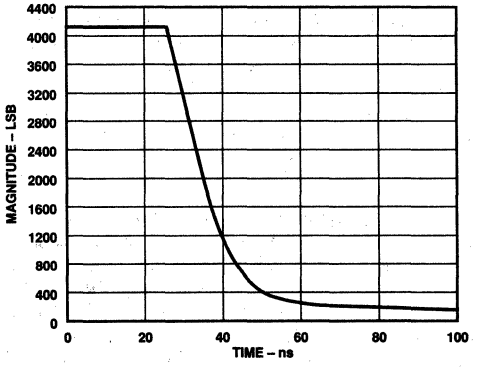

Figure 17. Typical AD871 Settling Time

The wide input bandwidth and superior dynamic performance of the input THA make the AD871 suitable for sampling inputs at frequencies up to the Nyquist Rate. The input THA is designed to recover rapidly from input overdrive conditions, returning from a 50% overdrive in less than 100 ns.

Because of the THA's exceptionally wide input bandwidth, some users may find the AD871 is sensitive to noise at frequencies from 10 MHz to 50 MHz that other converters are incapable of responding to. This sensitivity can be mitigated by careful use of the differential inputs (see previous paragraphs). Additionally, Figure 18 shows how a small capacitor (10 pF–20 pF for 50 Ω terminated inputs) may be placed between V_{INA} and V_{INB} to help reduce high frequency noise in applications where limiting the input bandwidth is acceptable.

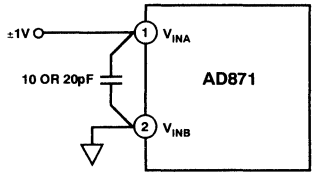

Figure 18. Optional High Frequency Noise Reduction

The AD871 will contribute its own wideband thermal noise. As a result of the integrated wideband noise (0.17 LSB rms, referred-to-input), applying a dc analog input may produce more than one code at the output. A histogram of the ADC output codes, for a dc input voltage, will be between 1 and 3 codes wide, depending on how well the input is centered on a given code and how many samples are taken. Figure 8 shows a typical AD871 code histogram, and Figure 9 illustrates the AD871's transition noise.

REFERENCE INPUT

The nominal reference input should be 2.5 V, taken with respect to REFERENCE GROUND (REF GND). Figure 19 illustrates the equivalent model for the reference input: there is no clock or signal-dependent activity associated with the reference input circuitry, therefore, no "kickback" into the reference.

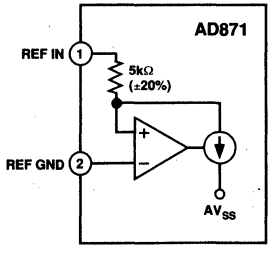

Figure 19. Equivalent Reference Input Circuit

However, in order to realize the lowest noise performance of the AD871, care should be taken to minimize noise at the reference input.

The AD871's reference input impedance is equal to 5 kΩ (±20%), and its effective noise bandwidth is 10 MHz, with a referred-to-input noise gain of 0.8. For example, the internal reference, with an rms noise of 28 μV (using an external 1 μF capacitor), contributes 24 μV (0.05 LSB) of noise to the transfer function of the AD871.

The full-scale peak-to-peak input voltage is a function of the reference voltage, according to the equation:

$$(V_{INA} - V_{INB})\ Full\ Scale = 0.8*(V_{REF} - REF\ GND)$$

Note that the AD871's performance was optimized for a 2.5 V reference input: performance may degrade somewhat for other reference voltages. Figure 20 illustrates the S/(N+D) performance vs. reference voltage for a 1 MHz, −0.5 dB input signal. Note also that if the reference is changed during a conversion, all three conversions in the pipeline will be invalidated.

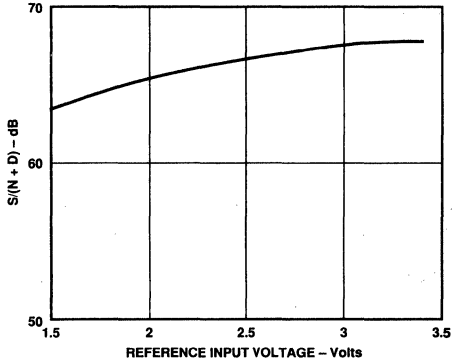

Figure 20. S/(N+D) vs. Reference Input Voltage, f_{IN} = 1 MHz, FS = 5 MHz

Table II summarizes various 2.5 V references suitable for use with the AD871, including the onboard bandgap reference (see REFERENCE OUTPUT section).

Table II. Suitable 2.5 V References

	Drift (PPM/°C)	Initial Accuracy %
REF-43B	6 (max)	0.2
AD680JN	10 (max)	0.4
Internal	30 (typ)	0.4

If an external reference is connected to REF IN, REF OUT must be connected to +5 V. This should lower the current in REF GND to less than 350 μA and eliminate the need for a 1 μF capacitor, although decoupling the reference for noise reduction purposes is recommended.

Alternatively, Figure 21 shows how the AD871 may be driven from other references by use of an external resistor. The external resistor forms a resistor divider with the on-chip 5 kΩ resistor to realize 2.5 V at the reference input pin (REF IN). A trim potentiometer is needed to accommodate the tolerance of the AD871's 5 kΩ resistor.

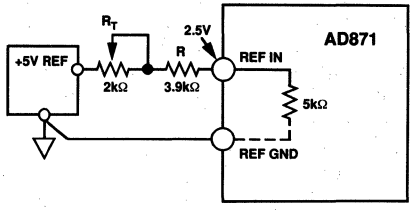

Figure 21. Optional +5 V Reference Input Circuit

REFERENCE GROUND

The REF GND pin provides the reference point for both the reference input, and the reference output. When the internal reference is operating, it will draw approximately 500 μA of current through the reference ground, so a low impedance path to the external common is desirable. The AD871 can tolerate a fairly large difference between REF GND and AGND, up to ±1 V, without any performance degradation.

REFERENCE OUTPUT

The AD871 features an onboard, curvature compensated bandgap reference that has been laser trimmed for both absolute value and temperature drift. The output stage of the reference was designed to allow the use of an external capacitor to limit the wideband noise. As Figure 22 illustrates, *a 1 μF capacitor on the reference output is required for stability of the reference output buffer.* Note: If used, an external reference may become unstable with this capacitor in place.

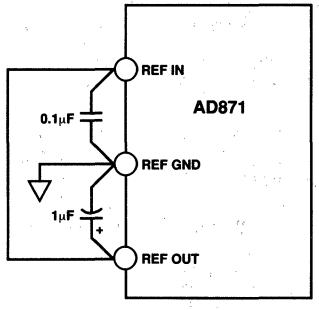

Figure 22. Typical Reference Decoupling Connection

With this capacitor in place, the noise on the reference output is approximately 28 μV rms at room temperature. Figure 23 shows the typical temperature drift performance of the reference, while Figure 24 illustrates the variation in reference voltage with load currents.

The output stage is designed to provide at least 2 mA of output current, allowing a single reference to drive up to four AD871s, or other external loads. The power supply rejection of the reference is better than 54 dB at dc.

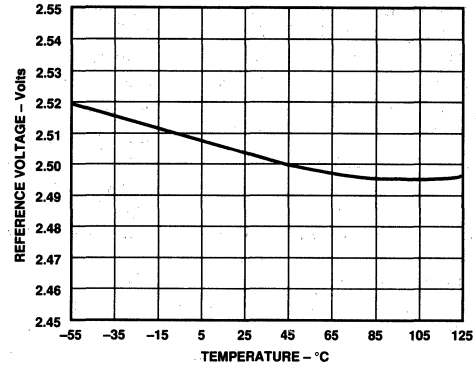

Figure 23. Reference Output Voltage vs. Temperature

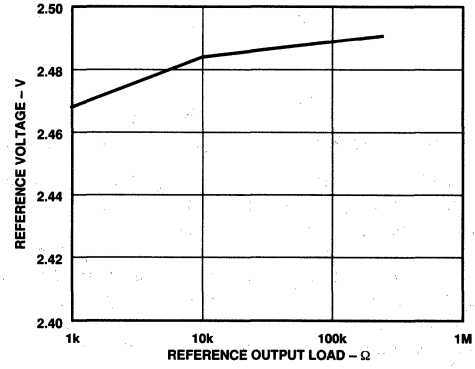

Figure 24. Reference Output Voltage vs. Output Load

DIGITAL OUTPUTS

In 28-pin packages, the AD871 output data is presented in twos complement format. Table III indicates offset binary and twos complement output for various analog inputs.

Table III. Output Data Format

Analog Input	Digital Output		
V_{INA}–V_{INB}	Offset Binary	Twos Complement	OTR
≥0.999756 V	1111 1111 1111	0111 1111 1111	1
0.999268 V	1111 1111 1111	0111 1111 1111	0
0 V	1000 0000 0000	0000 0000 0000	0
−1 V	0000 0000 0000	1000 0000 0000	0
−1.000244 V	0000 0000 0000	1000 0000 0000	1

Users requiring offset binary encoding may simply invert the $\overline{MSB}$ pin. In the 44-pin surface mount packages, both MSB and $\overline{MSB}$ bits are provided.

The AD871 features a digital out-of-range (OTR) bit that goes high when the input exceeds positive full scale or falls below negative full scale. As Table III indicates, the output bits will be set appropriately according to whether it is an out-of-range high condition or an out-of-range low condition. Note that if the input is driven beyond +1.5 V, the digital outputs may not stay at +FS, but may actually fold back to midscale.

The AD871's CMOS digital output drivers are sized to provide sufficient output current to drive a wide variety of logic families. However, large drive currents tend to cause glitches on the supplies and may affect S/(N+D) performance. Applications requiring the AD871 to drive large capacitive loads or large fanout may require additional decoupling capacitors on DRV_{DD} and DV_{DD}. In extreme cases, external buffers or latches could be used.

THREE-STATE OUTPUTS

The 44-pin surface mount AD871 offers three-state outputs. The digital outputs can be placed into a three-state mode by pulling the OUTPUT ENABLE (OEN) pin LOW. Note that this function is not intended to be used to pull the AD871 on and off a bus at 5 MHz. Rather, it is intended to allow the ADC to be pulled off the bus for evaluation or test modes. Also, to avoid corruption of the sampled analog signal during conversion (3 clock cycles), it is highly recommended that the AD871 be placed on the bus prior to the first sampling.

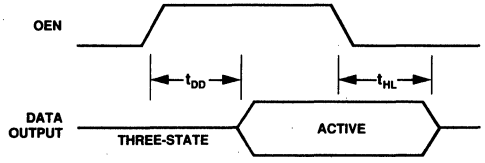

Figure 25. Three-State Output Timing Diagram

For timing budgetary purposes, the typical access and float delay times for the AD871 are 50 ns.

CLOCK INPUT

The AD871 internal timing control uses the two edges of the clock input to generate a variety of internal timing signals. The optimal clock input should have a 50% duty cycle; however, sensitivity to duty cycle is significantly reduced for clock rates of less than 5 megasamples per second.

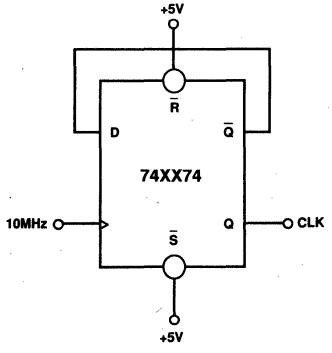

Figure 26. Divide-by-Two Clock Circuit

Due to the nature of on-chip compensation circuitry, the duty cycle should be maintained between 40% and 60% even for clock rates less than 5 Msps. One way to realize a 50% duty cycle clock is to divide down a clock of higher frequency, as shown in Figure 26.

In this case, a 10 MHz clock is divided by 2 to produce the 5 MHz clock input for the AD871. In this configuration, the duty cycle of the 10 MHz clock is irrelevant.

The input circuitry for the CLKIN pin is designed to accommodate both TTL and CMOS inputs. The quality of the logic input, particularly the rising edge, is critical in realizing the best possible jitter performance for the part: the faster the rising edge, the better the jitter performance.

As a result, careful selection of the logic family for the clock driver, as well as the fanout and capacitive load on the clock line, is important. Jitter-induced errors become more pronounced at higher frequency, large amplitude inputs, where the input slew rate is greatest.

The AD871 is designed to support a sampling rate of 5 Msps; running at slightly faster clock rates may be possible, although at reduced performance levels. Conversely, some slight performance improvements might be realized by clocking the AD871 at slower clock rates. Figure 27 presents the S/(N+D) vs. clock frequency for a 1 MHz analog input.

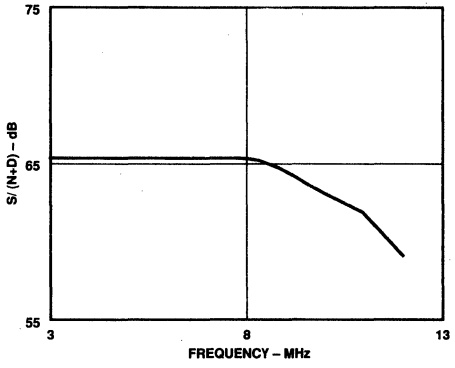

Figure 27. Typical S/(N+D) vs. Clock Frequency f_{IN} = 1 MHz, Full-Scale Input

The power dissipated by the correction logic and output buffers is largely proportional to the clock frequency; running at reduced clock rates provides a slight reduction in power consumption. Figure 28 illustrates this tradeoff.

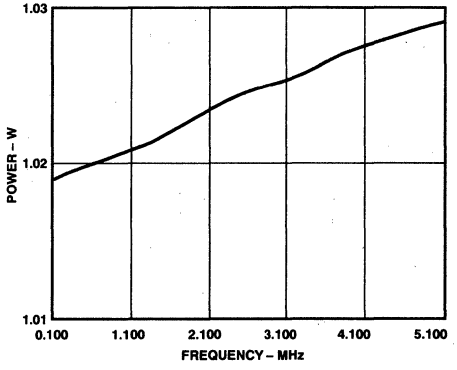

Figure 28. Typical Power Dissipation vs. Clock Frequency

ANALOG SUPPLIES AND GROUNDS

The AD871 features separate analog and digital supply and ground pins, helping to minimize digital corruption of sensitive analog signals. In general, AV_{SS} and AV_{DD}, the analog supplies,

should be decoupled to AGND, the analog common, as close to the chip as physically possible. Care has been taken to minimize the signal dependence of the power supply currents; however, the analog supply currents will be proportional to the reference input. With REFIN at 2.5 V, the typical current into AV_{DD} is 82 mA, while the typical current out of AV_{SS} is 115 mA. Typically, 33 mA will flow into the AGND pin.

Careful design and the use of differential circuitry provide the AD871 with excellent rejection of power supply noise over a wide range of frequencies, as illustrated in Figure 29.

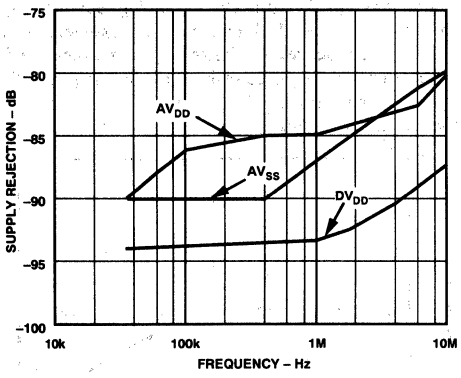

Figure 29. Power Supply Rejection vs. Frequency, 100 mV p-p Signal on Power Supplies

Figure 30 shows the degradation in SNR resulting from 100 mV of power supply ripple at various frequencies. As Figure 30 shows, careful decoupling is required to realize the specified dynamic performance. Figure 34 demonstrates the recommended decoupling strategy for the supply pins. Note that in extremely noisy environments, a more elaborate supply filtering scheme may be necessary.

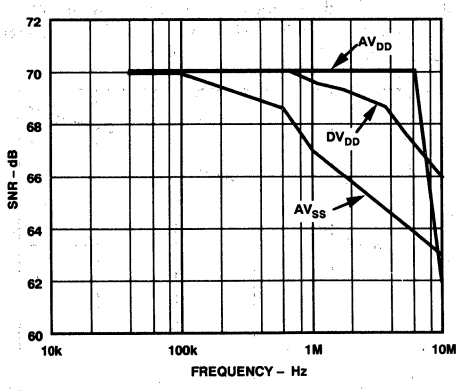

Figure 30. SNR vs. Supply Noise Frequency (f_{IN} = 1 MHz)

DIGITAL SUPPLIES AND GROUNDS

The digital activity on the AD871 chip falls into two general categories: CMOS correction logic, and CMOS output drivers. The internal correction logic draws relatively small surges of current, mainly during the clock transitions; in the 44-pin package, these currents flow through pins DGND and DV_{DD}. The output drivers draw large current impulses while the output bits are changing. The size and duration of these currents is a function of the load on the output bits: large capacitive loads are to be avoided. In the 44-pin package, the output drivers are supplied through dedicated pins DRGND and DRV_{DD}. Pin count constraints in the 28-pin packages require that the digital and driver supplies share package pins (although they have separate bond wires and on-chip routing). The decoupling shown in Figure 34 is appropriate for a reasonable capacitive load on the digital outputs (typically 20 pF on each pin). Applications involving greater digital loads should consider increasing the digital decoupling proportionately, and/or using external buffers/latches.

APPLICATIONS

OPTIONAL ZERO AND GAIN TRIM

The AD871 is factory trimmed to minimize zero error, gain error and linearity errors. In some applications the zero and gain errors of the AD871 need to be externally adjusted to zero. If required, both zero error and gain error can be trimmed with external potentiometers as shown in Figure 31. Note that gain error adjustments must be made with an external reference.

Zero trim should be adjusted first. Connect V_{INA} to ground and adjust the 10 kΩ potentiometer such that a nominal digital output code of 0000 0000 0000 (twos complement output) exists. Note that the zero trim should be decoupled and that the accuracy of the ±2.5 V reference signals will directly affect the offset.

Gain error may then be calibrated by adjusting the REF IN voltage. The REF IN voltage should be adjusted such that a +1 V input on V_{INA} results in the digital output code 01111 1111 1111 (twos complement output).

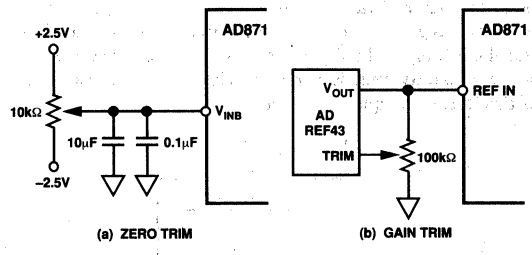

Figure 31. Zero and Gain Error Trims

DIGITAL OFFSET CORRECTION

The AD871 provides differential inputs that may be used to correct for any offset voltages on the analog input. For applications where the input signal contains a dc offset, it may be advantageous to apply a nulling voltage to the V_{INB} input. Applying a voltage equal to the dc offset will maximize the full-scale input range and therefore the dynamic range. Offsets ranging from −0.7 V to +0.5 V can be corrected.

Figure 32 shows how a dc offset can be applied using the AD568 12-bit, high speed digital-to-analog converter (DAC). This circuit can be used for applications requiring offset adjustments on every clock cycle. The AD568 connection scheme is used to provide a −0.512 V to +0.512 V output range. The offset voltage must be stable on the rising edge of the AD871 clock input.

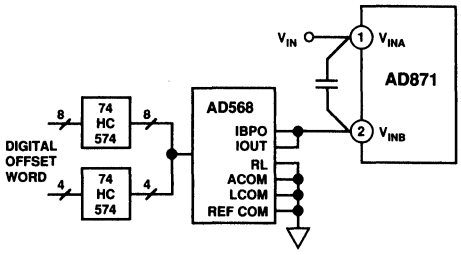

Figure 32. Offset Correction Using the AD568

UNDERSAMPLING USING THE AD871 AND AD9100

The AD871's on-chip THA optimizes transient response while maintaining low noise performance. For super-Nyquist (undersampling) applications it may be necessary to use an external THA with fast track-mode slew rate and hold mode settling time. An excellent choice for this application is the AD9100, an ultrahigh speed track-and-hold amplifier.

In order to maximize the spurious free dynamic range of the circuit in Figure 33 it is advantageous to present a small signal to the input of the AD9100 and then amplify the output to the AD871's full-scale input range. This can be accomplished with a low distortion, wide bandwidth amplifier such as the AD9617. The circuit uses a gain of 3.5 to optimize S/(N+D).

The peak performance of this circuit is obtained by driving the AD871 + AD9100 combination with a full-scale input. For small scale input signals (−20dB, −40 dB), the AD871 performs better without the track-and-hold because slew-limiting effects are no longer dominant. To gain the advantages of the added track-and-hold, it is important to give the AD871 a full-scale input.

An alternative to the configuration presented above is to use the AD9101 track-and-hold amplifier. The AD9101 provides a built-in post amplifier with a gain of 4, providing excellent ac characteristics in conjunction with a high level of integration.

As illustrated in Figure 33, it is necessary to skew the AD871 sample clock and the AD9100 sample/hold control. Clock skew (t_S) is defined as the time starting at the AD9100's transition into hold mode and ending at the moment the AD871 samples. The AD871 samples on the rising edge of the sample clock, and the AD9100 samples on the falling edge of the sample/hold control. The choice of t_S is primarily determined by the settling time of the AD9100. The droop rate of the AD9100 must also be taken into consideration. Using these values, the ideal t_S is 17 ns. When choosing clock sources, it is extremely important that the front end track-and-hold sample/hold control is given a very low jitter clock source. This is not as crucial for the AD871 sample clock, because it is sampling a dc signal.

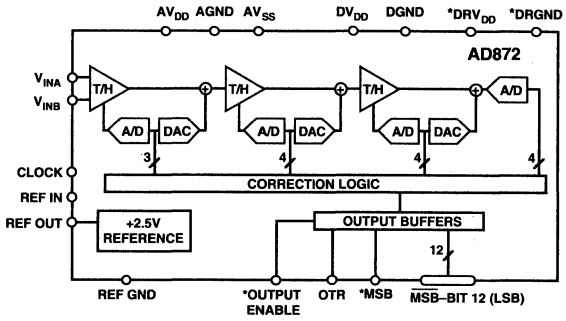
Complete 12-Bit 10 MSPS Monolithic A/D Converter

AD872

FEATURES

Monolithic 12-Bit 10 MSPS A/D Converter
Low Power Dissipation: 1.15 W
No Missing Codes Guaranteed
Differential Nonlinearity Error: 0.5 LSB
Complete: On-Chip Track-and-Hold Amplifier and Voltage Reference
Signal-to-Noise and Distortion Ratio: 65 dB
Spurious-Free Dynamic Range: 72 dB
Out of Range Indicator
Twos Complement Binary Output Data
28-Pin Ceramic DIP or 44-Pin Surface Mount Package

FUNCTIONAL BLOCK DIAGRAM



* ONLY AVAILABLE ON 44 PIN SURFACE MOUNT PACKAGE.

PRODUCT DESCRIPTION

The AD872 is a monolithic 12-bit, 10 Msps analog to digital converter with an on-chip, high performance track-and-hold amplifier and voltage reference. The AD872 uses a multistage differential pipelined architecture with output error correction logic to provide 12-bit accuracy at 10 Msps data rates and guarantees no missing codes over the full operating temperature range. The AD872 combines a merged high speed bipolar/CMOS process and a novel architecture to achieve the resolution and speed of hybrid implementations at a fraction of the power consumption. Additionally, the greater reliability of monolithic construction offers improved system reliability and lower costs than hybrid designs.

The high input impedance, fast-settling input track-and-hold (T/H) amplifier is equally suited for both multiplexed systems that switch negative to positive full-scale voltage levels in successive channels and sampling single-channel inputs at frequencies up to and beyond the Nyquist rate. The AD872's wideband input combined with the power and cost savings over previously available hybrids will allow new design opportunities in communications, imaging and medical applications. The AD872 provides both reference output and reference input pins, allowing the onboard reference to serve as a system reference. An external reference can also be chosen to suit the dc accuracy and temperature drift requirements of the application. A single clock input is used to control all internal conversion cycles. The digital output data is presented in twos complement binary output format. An out-of-range signal indicates an overflow condition. It can be used with the most significant bit to determine low or high overflow.

The AD872 is fabricated on Analog Devices ABCMOS-1 process which utilizes high speed bipolar and CMOS transistors on a single chip. High speed, precision analog circuits are now combined with high density logic circuits.

The AD872 is packaged in a 28-pin ceramic DIP and a 44-pin leadless ceramic surface mount package and is specified for operation from 0°C to +70°C and −55°C to +125°C.

PRODUCT HIGHLIGHTS

The AD872 offers a complete single-chip sampling 12-bit, 10 Msps analog-to-digital conversion function in a 28-pin DIP or 44-pin leadless ceramic surface mount package (LCC).

Low Power—The AD872 at 1.15 W consumes a fraction of the power of presently available hybrids.

Onboard Track-and-Hold (T/H)—The high impedance T/H input eliminates the need for external buffers and can be configured for single ended or differential inputs.

Out of Range (OTR)—The OTR output bit indicates when the input signal is beyond the AD872's input range.

Ease-of-Use—The AD872 is complete with T/H and voltage reference.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD872—SPECIFICATIONS

DC SPECIFICATIONS (T_{MIN} to T_{MAX} with AV_{DD} = +5 V, DV_{DD} = +5 V, AV_{SS} = −5 V, f_{SAMPLE} = 10 MHz unless otherwise indicated)

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.
[2]LCC Package Only.

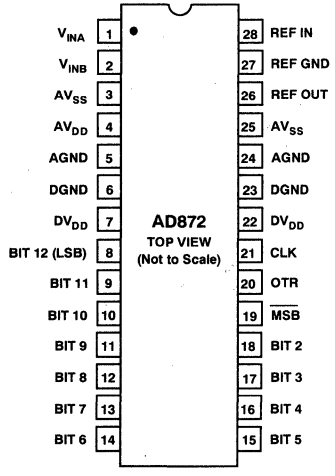
PIN DESCRIPTION

Symbol	DIP Pin No.	LCC Pin No.	Type	Name and Function
AGND	5, 24	9, 36	P	Analog Ground.
AV_{DD}	4	6, 38	P	+5 V Analog Supply.
AV_{SS}	3, 25	5, 40	P	−5 V Analog Supply.
$\overline{MSB}$	19	29	DO	Inverted Most Significant Bit. Provides twos complement output data format.
MSB	N/A	27	DO	Most Significant Bit.
BIT 2–BIT 11	18–9	26–17	DO	Data Bits 2 through 11.
BIT 12 (LSB)	8	16	DO	Least Significant Bit.
CLK	21	31	DI	Clock Input. The AD872 will initiate a conversion on the rising edge of the clock input. See the Timing Diagram for details.
DV_{DD}	7, 22	33	P	+5 V Digital Supply.
DGND	6, 23	10	P	Digital Ground.
DRV_{DD}	N/A	12, 32	P	+5 V Digital Supply for the output drivers.
DRGND	N/A	11, 34	P	Digital Ground for the output drivers. (See section on Power Supply Decoupling for details on DRV_{DD} and DRGND.)
OTR	20	30	DO	Out of Range is Active HIGH on the leading edge of code 0 or the trailing edge of code 4096. See Output Data Format Table III.
OEN	N/A	13	DI	Output Enable. See the Three State Output Timing Diagram for details.
REF GND	27	42	AI	Reference Ground.
REF IN	28	43	AI	Reference Input. +2.5 V input gives ±1 V full-scale range.
REF OUT	26	41	AO	+2.5 V Reference Output. Tie to REF IN for normal operation.
V_{INA}	1	1	AI	(+) Analog Input Signal on the differential input amplifier.
V_{INB}	2	2	AI	(−) Analog Input Signal on the differential input amplifier.
NC	N/A	3, 4, 7, 8, 14, 15 28, 35, 37, 39, 44		No Connect.

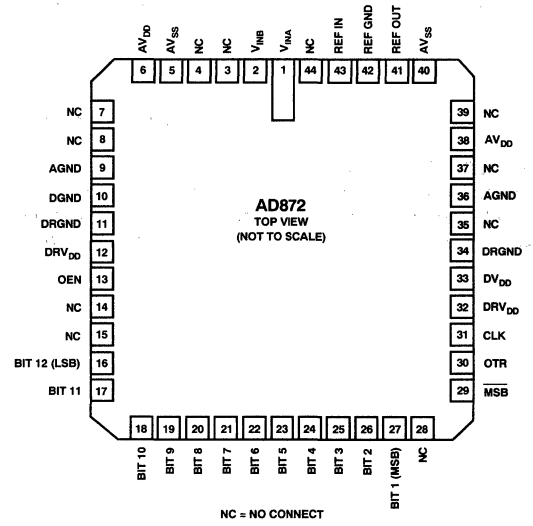
TYPE: AI = Analog Input; AO = Analog Output; DI = Digital Input; DO = Digital Output; P = Power; N/A = Not Available on 28-pin DIP. Only available on 44-pin surface mount package.

PIN CONFIGURATIONS

28-Pin Ceramic DIP



44-Pin LCC



DEFINITIONS OF SPECIFICATIONS

LINEARITY ERROR

Linearity error refers to the deviation of each individual code from a line drawn from "negative full scale" through "positive full scale." The point used as "negative full scale" occurs 1/2 LSB before the first code transition. "Positive full scale" is defined as a level 1 1/2 LSB beyond the last code transition. The deviation is measured from the middle of each particular code to the true straight line.

DIFFERENTIAL LINEARITY ERROR (DNL, NO MISSING CODES)

An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. Guaranteed no missing codes to 12-bit resolution indicates that all 4096 codes must be present over all operating ranges.

ZERO ERROR

The major carry transition should occur for an analog value 1/2 LSB below analog common. Zero error is defined as the deviation of the actual transition from that point. The zero error and temperature drift specify the initial deviation and maximum change in the zero error over temperature.

GAIN ERROR

The first code transition should occur for an analog value 1/2 LSB above nominal negative full scale. The last transition should occur for an analog value 1 1/2 LSB below the nominal positive full scale. Gain error is the deviation of the actual difference between first and last code transitions and the ideal difference between first and last code transitions.

TEMPERATURE DRIFT

The temperature drift for zero error and gain error specifies the maximum change from the initial (25°C) value to the value at T_{MIN} or T_{MAX}.

POWER SUPPLY REJECTION

The specifications show the maximum change in the converter's full scale as the supplies are varied from nominal to min/max values.

APERTURE JITTER

Aperture jitter is the variation in aperture delay for successive samples and is manifested as noise on the input to the A/D.

APERTURE DELAY

Aperture delay is a measure of the Track-and-Hold Amplifier (THA) performance and is measured from the rising edge of the clock input to when the input signal is held for conversion.

OVERVOLTAGE RECOVERY TIME

Overvoltage recovery time is defined as that amount of time required for the ADC to achieve a specified accuracy after an overvoltage (50% greater than full-scale range), measured from the time the overvoltage signal reenters the converter's range.

DYNAMIC SPECIFICATIONS

SIGNAL-TO-NOISE AND DISTORTION (S/N+D) RATIO

S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

TOTAL HARMONIC DISTORTION (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

INTERMODULATION DISTORTION (IMD)

With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb), and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (2 fb − fa). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

FULL-POWER BANDWIDTH

The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

SPURIOUS FREE DYNAMIC RANGE

The difference, in dB, between the rms amplitude of the input signal and the peak spurious signal.

ORDERING GUIDE

Model	Temperature Range	Package Option[1]
AD872JD	0°C to +70°C	D-28
AD872JE	0°C to +70°C	E-44A

THEORY OF OPERATION

The AD872 is implemented using a 4-stage pipelined multiple flash architecture. A differential input track-and-hold amplifier (THA) acquires the input and converts the input voltage into a differential current. A 3-bit approximation of the input is made by the first flash converter, and an accurate analog representation of this 3-bit guess is generated by a digital-to-analog converter. This approximation is subtracted from the THA output to produce a remainder, or residue. This residue is then sampled and held by the second THA, and a 4-bit approximation is generated and subtracted by the second stage. Once the second THA goes into hold, the first stage goes back into track to acquire a new input signal. The third stage provides another 4-bit approximation/subtraction operation, and produces the final residue, which is passed to a final 4-bit flash converter. The 15 output bits from the 4 flash converters are accumulated in the correction logic block, which adds the bits together using the appropriate correction algorithm, to produce the 12-bit output word. The digital output, together with overrange indicator, is latched into an output buffer to drive the output pins.

The additional THA inserted in each stage of the AD872 architecture allows pipelining of the conversion. In essence, the converter is converting multiple inputs simultaneously, processing them through the converter chain serially. This means that while the converter is capable of capturing a new input sample every clock cycle, it actually takes three clock cycles for the conversion to be fully processed and appear at the output. This "pipeline delay" is often referred to as latency, and is not a concern in most applications, however there are some cases where it may be a consideration. For example, some applications call for the A/D converter to be placed in a high speed feedback loop, where its input is servoed to provide a desired result at the digital output (e.g., offset calibration or zero restoration in video applications). In these cases the 3 clock cycle delay through the pipeline must be accounted for in the loop stability calculations. Also, because the converter is working on three conversions simultaneously, major disruptions to the part (such as a large glitch on the supplies or reference) may corrupt three data samples. Finally, there will be a minimum clock rate below which the THA droop corrupts the signal in the pipeline. In the case of the AD872, this minimum clock rate is 10 kHz.

The high impedance differential inputs of the AD872 allow a variety of input configurations (see APPLYING THE AD872). The AD872 converts the voltage difference between the V_{INA} and V_{INB} pins. For single-ended applications, one input pin (V_{INA} or V_{INB}) may be grounded, but even in this case the differential input can provide a performance boost: for example, for an input coming from a coaxial cable, V_{INB} can be tied to the shield ground, allowing the AD872 to reject shield noise as common mode. The high input impedance of the device minimizes external driving requirements and allows the user to externally select the appropriate termination impedance for the application.

The AD872 clock circuitry uses both edges of the clock in its internal timing circuitry (see spec page for exact timing requirements.) The AD872 samples the analog input on the rising edge of the clock input. During the clock low time (between the falling edge and rising edge of the clock) the input THA is in track mode; during the clock high time it is in hold. System disturbances just prior to the rising edge of the clock may cause the part to acquire the wrong value, and should be minimized.

While the part uses both clock edges for its timing, jitter is only a significant issue for the rising edge of the clock (see CLOCK INPUT section).

APPLYING THE AD872

ANALOG INPUTS

The AD872 features a high impedance differential input that can readily operate on either single-ended or differential input signals. Table I summarizes the nominal input voltage span for both single-ended and differential modes, assuming a 2.5 V reference input.

Table I. Input Voltage Span

	V_{INA}	V_{INB}	$V_{INA}-V_{INB}$
Single-Ended	+1 V	GND	+1 V (Positive Full Scale)
	−1 V	GND	−1 V (Negative Full Scale)
Differential	+0.5 V	−0.5 V	+1 V (Positive Full Scale)
	−0.5 V	+0.5 V	−1 V (Negative Full Scale)

Figure 10 shows an approximate model for the analog input circuit. As this model indicates, when the input exceeds 1.6 V (with respect to AGND), the input device may saturate, causing the input impedance to drop substantially and significantly reducing the performance of the part. Input compliance in the negative direction is somewhat larger, showing virtually no degradation in performance for inputs as low as −1.9 V.

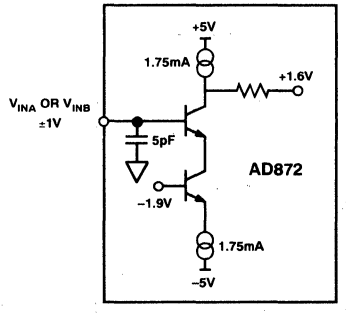

Figure 10. AD872 Equivalent Analog Input Circuit

Figure 11 illustrates the effect of varying the common-mode voltage of a −1 dB input signal on total harmonic distortion.

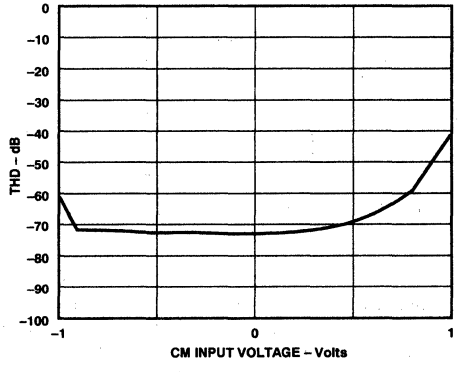

Figure 11. AD872 Total Harmonic Distortion vs. CM Input Voltage, f_{IN} = 1 MHz, FS = 10 MSPS

Figure 12 shows the common-mode rejection performance vs. frequency for a 1 V p-p common mode input. This excellent common-mode rejection out over a wide bandwidth affords the user the opportunity to eliminate many potential sources of input noise as common mode by using the differential input structure of the AD872.

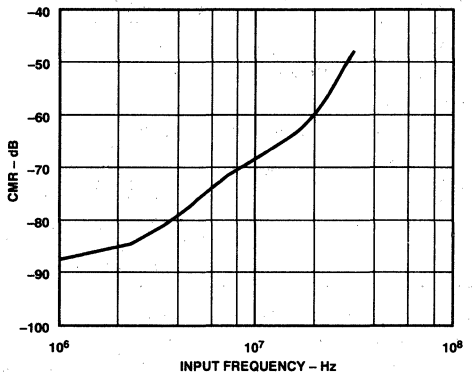

Figure 12. Common-Mode Rejection vs. Input Frequency, 1 V p-p Input

Figures 13 and 14 illustrate typical input connections for single-ended inputs.

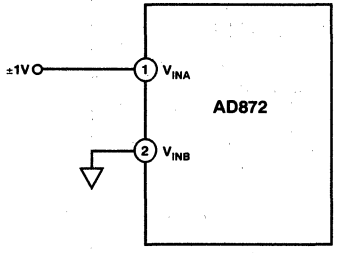

Figure 13. AD872 Single-Ended Input Connection

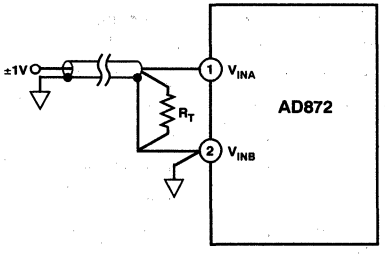

Figure 14. AD872 Single-Ended Input Connection Using a Shielded Cable

The cable shield is used as the ground connection for the V_{INB} input, providing the best possible rejection of the cable noise from the input signal. Note also that the high input impedance of the AD872 allows the user to select his own termination impedance, be it 50 ohms, 75 ohms, or some other value. Furthermore, unlike many flash converters, most AD872 applications will not require an external buffer amplifier. If such an amplifier is required, we suggest either the AD811 or AD9617.

Figure 15 illustrates how external amplifiers may be used to convert a single-ended input into a differential signal. The resistor values of 536 Ω and 562 Ω were selected to provide optimum phase matching between U1 and U2.

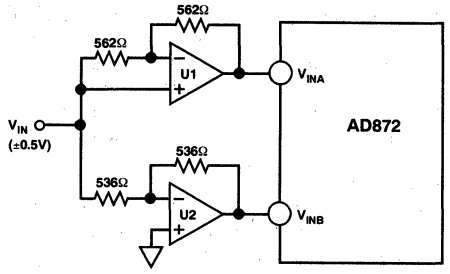

Figure 15. Single-Ended to Differential Connections; U1, U2 = AD811 or AD9617

The use of the differential input signal can help to minimize even-order distortion from the input THA where performance beyond −70 dB is desired.

Figure 16 shows the AD872 large signal (−0.5 dB) and small signal (−20 dB) frequency response.

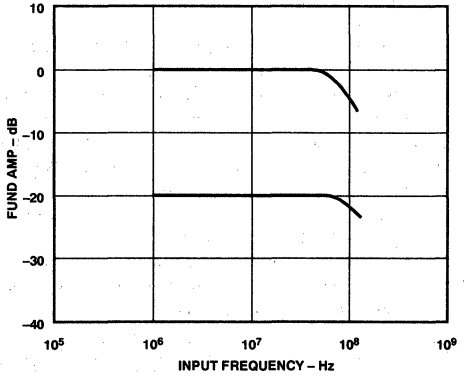

Figure 16. Full Power (−0.5 dB) and Small Signal Response (−20 dB) vs. Input Frequency

The AD872's wide input bandwidth facilitates rapid acquisition of transient input signals: the input THA can typically settle to 12-bit accuracy from a full-scale input step in less than 40 ns. Figure 17 illustrates the typical acquisition of a full-scale input step.

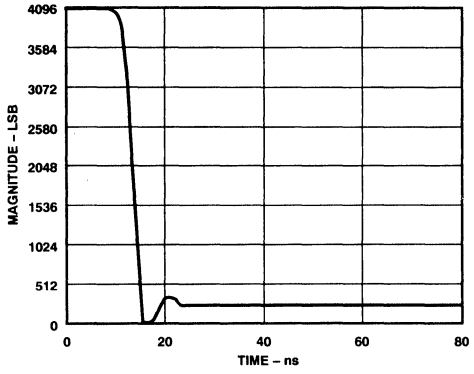

Figure 17. Typical AD872 Settling Time

The wide input bandwidth and superior dynamic performance of the input THA makes the AD872 suitable for undersampling applications where the input frequency exceeds half the sampling frequency. The input THA is designed to recover rapidly from input overdrive conditions, returning from a 50% overdrive in less than 50 ns.

Because of the THA's exceptionally wide input bandwidth, some users may find the AD872 is sensitive to noise at frequencies from 50 MHz to 100 MHz that other converters are incapable of responding to. This sensitivity can be mitigated by careful use of the differential inputs (see previous paragraphs). Additionally, Figure 18 shows how a small capacitor (10 pF–20 pF for 50-ohm terminated inputs) may be placed between V_{INA} and V_{INB} to help reduce high frequency noise in applications where limiting the input bandwidth is acceptable.

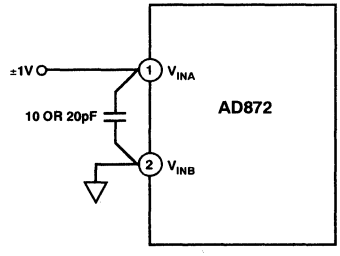

Figure 18. Optional High Frequency Noise Reduction

The AD872 will contribute its own wideband thermal noise. As a result of the integrated wideband noise (1/2 LSB rms, referred-to-input), applying a dc analog input produces more than one code at the output. A histogram analysis of the AD872 with a dc input will show a bell shaped curve consistent with the Guassian nature of the thermal noise. This histogram will be between 3 and 5 codes wide, depending on how well the input is centered on a given code and how many samples are taken.

REFERENCE INPUT

The nominal reference input should be 2.5 V, taken with respect to REFERENCE GROUND (REF GND). Figure 19 illustrates the equivalent model for the reference input: there is no clock or signal-dependent activity associated with the reference input circuitry, therefore, no "kickback" into the reference.

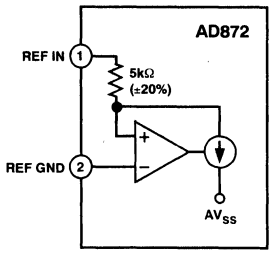

Figure 19. Equivalent Reference Input Circuit

The AD872's input impedance is 5 kΩ, with a tolerance of ±20%. The effective noise bandwidth through the input channel is 10 MHz, and the referred-to-input noise gain is 0.4. For example, the internal reference, with peak-to-peak noise of 180 μV (using an external 1 μF capacitor), contributes 0.3 LSBs of noise to the transfer function of the AD872.

The full-scale peak-to-peak input voltage is a function of the reference voltage, according to the equation:

$$(V_{INA} - V_{INB})\ Full\ Scale = 0.8*(V_{REF} - REF\ GND)$$

Note that the AD872's performance was optimized for a 2.5 V reference input: performance will degrade somewhat for other reference voltages. Figure 20 illustrates the S/(N+D) performance vs. reference voltage for a 1 MHz, −0.5 dB input signal. Note also that if the reference is changed during a conversion, all three conversions in the pipeline will be invalidated.

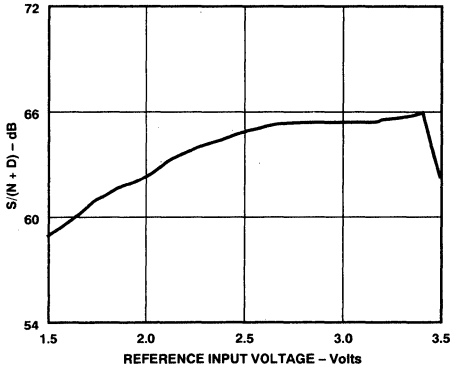

Figure 20. S/(N+D) vs. Reference Input Voltage, f_{IN} = 1 MHz, FS = 10 MHz

Table II summarizes various 2.5 V references suitable for use with the AD872, including the onboard bandgap reference (see REFERENCE OUTPUT section).

Table II. Suitable 2.5 V References

	Drift (PPM/°C)	Initial Accuracy %
REF-43B	6 (max)	0.2
AD680JN	10 (max)	0.4
Internal	30 (typ)	0.4

If an external reference is connected to REF IN, REF OUT must be connected to +5 V. This should lower the current in REF GND to less than 350 μA, and eliminate the need for a 1 μF capacitor.

Alternatively, Figure 21 shows how the AD872 may be driven from other references by use of an external resistor. The external resistor forms a resistor divider with the on-chip 5 kΩ resistor to realize 2.5 V at the reference input pin (REF IN). A trim potentiometer is recommended to accommodate the tolerance of the AD872's 5 kΩ resistor.

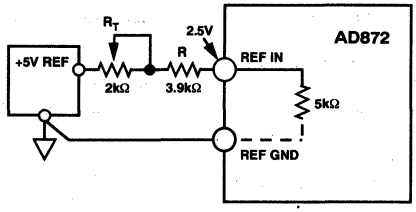

Figure 21. Optional +5 V Reference Input Circuit

REFERENCE GROUND

The REF GND pin provides the reference point for both the reference input, and the reference output. When the internal reference is operating, it will draw approximately 500 μA of current through the reference ground, so a low impedance path to the external common is desirable. The AD872 can tolerate a fairly large difference between REF GND and AGND, up to ±1 V, without any performance degradation.

REFERENCE OUTPUT

The AD872 features an onboard, curvature compensated bandgap reference that has been laser trimmed for both absolute value and temperature drift. The output stage of the reference was designed to allow the use of an external capacitor to limit the wideband noise. As Figure 22 illustrates, *a 1 μF capacitor on the reference output is required for stability of the reference output buffer.* Note: If used, an external reference may become unstable with this capacitor in place.

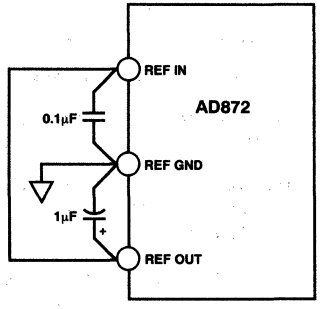

Figure 22. Typical Reference Decoupling Connection

With this capacitor in place, the noise on the reference output is approximately 30 μV rms at room temperature. Figure 23 shows the typical temperature drift performance of the reference, while Figure 24 illustrates the variation in reference voltage with load currents.

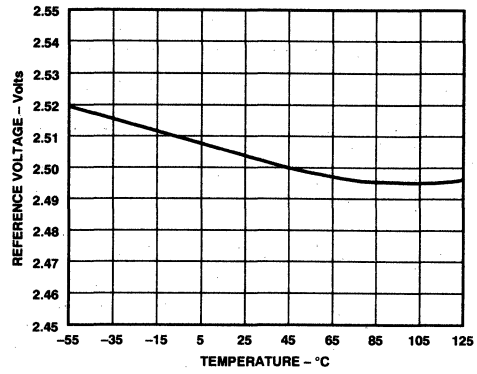

Figure 23. Reference Output Voltage vs. Temperature

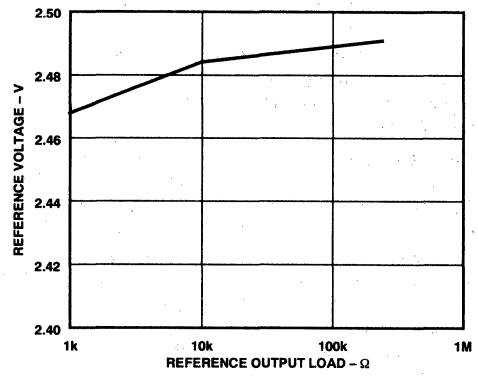

Figure 24. Reference Output Voltage vs. Output Load

The output stage is designed to provide at least 2 mA of output current, allowing a single reference to drive up to four AD872s, or other external loads. The power supply rejection of the reference is better than 54 dB at dc.

DIGITAL OUTPUTS

In 28-pin packages, the AD872 output data is presented in twos complement format. Table III indicates offset binary and twos complement output for various analog inputs.

Table III. Output Data Format

Analog Input	Digital Output		
V_{INA}–V_{INB}	Offset Binary	Twos Complement	OTR
≥0.999756 V	1111 1111 1111	0111 1111 1111	1
0.999268 V	1111 1111 1111	0111 1111 1111	0
0 V	1000 0000 0000	0000 0000 0000	0
−1 V	0000 0000 0000	1000 0000 0000	0
−1.000244 V	0000 0000 0000	1000 0000 0000	1

Users requiring offset binary encoding may simply invert the $\overline{\text{MSB}}$ pin. In the 44-pin surface mount packages, both MSB and $\overline{\text{MSB}}$ bits are provided.

The AD872 features a digital out-of-range (OTR) bit that goes high when the input exceeds positive full scale or falls below negative full scale. As Table III indicates, the output bits will be

set appropriately according to whether it is an out-of-range high condition or an out-of-range low condition.

The AD872's CMOS digital output drivers are sized to provide sufficient output current to drive a wide variety of logic families. However, large drive currents tend to cause glitches on the supplies and may affect S/(N+D) performance. Applications requiring the AD872 to drive large capacitive loads or large fanout may require additional decoupling capacitors on DRV_{DD} and DV_{DD}. In extreme cases, external buffers or latches could be used.

THREE-STATE OUTPUTS

The 44-pin surface mount AD872 offers three-state outputs. The digital outputs can be placed into a three-state mode by pulling the OUTPUT ENABLE (OEN) pin LOW. Note that this function is not intended to be used to pull the AD872 on and off a bus at 10 MHz. Rather, it is intended to allow the ADC to be pulled off the bus for evaluation or test modes. Also, to avoid corruption of the sampled analog signal during conversion (3 clock cycles), it is highly recommended that the AD872 be placed on the bus prior to the first sampling.

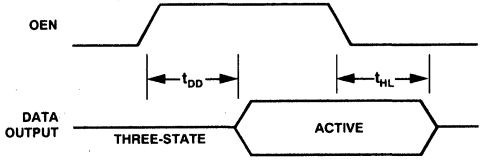

Figure 25. Three-State Output Timing Diagram

For timing budgetary purposes, the maximum access and float delay times for the AD872 are 200 ns.

CLOCK INPUT

The AD872 internal timing control uses the two edges of the clock input to generate a variety of internal timing signals. The optimal clock input should have a 50% duty cycle; however, sensitivity to duty cycle is significantly reduced for clock rates of less than 10 megasamples per second.

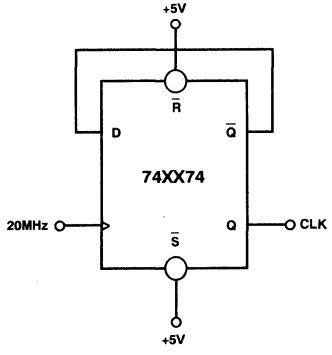

Figure 26. Divide-by-Two Clock Circuit

Due to the nature of on-chip compensation circuitry, the duty cycle should be maintained between 40% and 60% even for clock rates less than 10 Msps. One way to realize a 50% duty cycle clock is to divide down a clock of higher frequency, as shown in Figure 26.

In this case, a 20 MHz clock is divided by 2 to produce the 10 MHz clock input for the AD872. In this configuration, the duty cycle of the 20 MHz clock is irrelevant.

The input circuitry for the CLKIN pin is designed to accommodate both TTL and CMOS inputs. The quality of the logic input, particularly the rising edge, is critical in realizing the best possible jitter performance for the part: the faster the rising edge, the better the jitter performance.

As a result, careful selection of the logic family for the clock driver, as well as the fanout and capacitive load on the clock line, is important. Jitter-induced errors become more predominant at higher frequency, large amplitude inputs, where the input slew rate is greatest.

The AD872 is designed to support a sampling rate of 10 Msps; running at slightly faster clock rates may be possible, although at reduced performance levels. Conversely, some slight performance improvements might be realized by clocking the AD872 at slower clock rates. Figure 27 presents the SNR vs. clock frequency for a 1 MHz analog input.

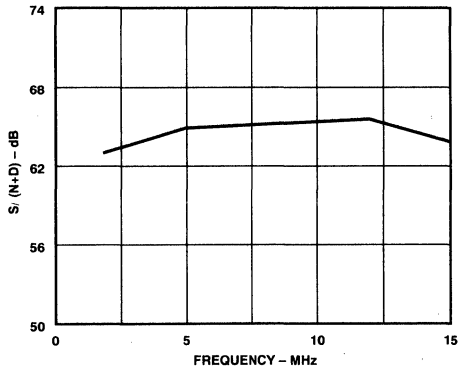

Figure 27. Typical S/(N+D) vs. Clock Frequency f_{IN} = 1 MHz, Full-Scale Input

The power dissipated by the correction logic and output buffers is largely proportional to the clock frequency; running at reduced clock rates provides a slight reduction in power consumption. Figure 28 illustrates this tradeoff.

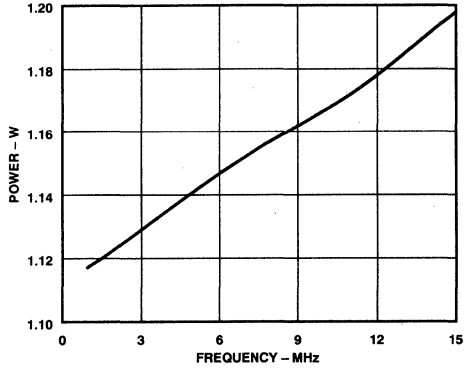

Figure 28. Typical Power Dissipation vs. Clock Frequency

ANALOG SUPPLIES AND GROUNDS

The AD872 features separate analog and digital supply and ground pins, helping to minimize digital corruption of sensitive analog signals. In general, AV_{SS} and AV_{DD}, the analog supplies, should be decoupled to AGND, the analog common, as close to the chip as physically possible. Care has been taken to minimize the signal dependence of the power supply currents; however, the analog supply currents will be proportional to the reference input. With REFIN at 2.5 V, the typical current into AV_{DD} is 78 mA, while the typical current out of AV_{SS} is 134 mA. Typically, 55 mA will flow into the AGND pin.

Careful design and the use of differential circuitry provide the AD872 with excellent rejection of power supply noise over a wide range of frequencies, as illustrated in Figure 29.

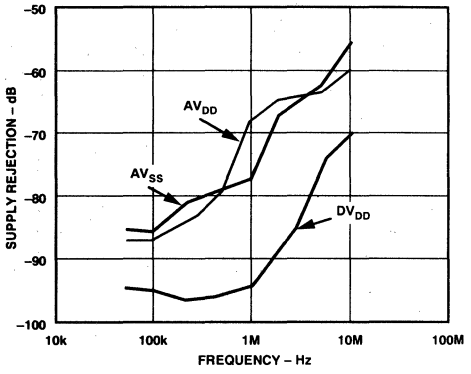

Figure 29. Power Supply Rejection vs. Frequency, 100 mV p-p Signal on Power Supplies

Figure 30 shows the degradation in SNR ratio resulting from 100 mV of power supply ripple at various frequencies. As Figure 30 shows, careful decoupling is required to realize the specified dynamic performance. Figure 35 demonstrates the recommended decoupling strategy for the supply pins. Note that in extremely noisy environments, a more elaborate supply filtering scheme may be necessary.

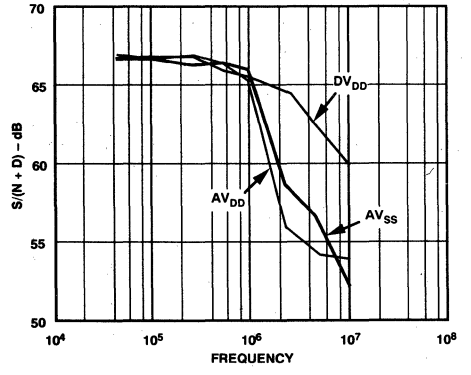

Figure 30. SNR vs. Supply Noise Frequency (f_{IN} = 1 MHz)

DIGITAL SUPPLIES AND GROUNDS

The digital activity on the AD872 chip falls into two general categories: CMOS correction logic, and CMOS output drivers. The internal correction logic draws relatively small surges of current, mainly during the clock transitions; in the 44-pin package, these currents flow through pins DGND and DV_{DD}. The output drivers draw large current impulses while the output bits are changing. The size and duration of these currents is a function of the load on the output bits: large capacitive loads are to be avoided. In the 44-pin package, the output drivers are supplied through dedicated pins DRGND and DRV_{DD}. Pin count constraints in the 28-pin packages require that the digital and driver supplies share package pins (although they have separate bond wires and on-chip routing). The decoupling shown in Figure 35 is appropriate for a reasonable capacitive load on the digital outputs (typically 20 pF on each pin). Applications involving greater digital loads should consider increasing the digital decoupling proportionately.

APPLICATIONS

OPTIONAL ZERO AND GAIN TRIM

The AD872 is factory trimmed to minimize zero error, gain error and linearity errors. In some applications the zero and gain errors of the AD872 need to be externally adjusted to zero. If required, both zero error and gain error can be trimmed with external potentiometers as shown in Figure 31. Note that gain error adjustments must be made with an external reference.

Zero trim should be adjusted first. Connect V_{INA} to ground and adjust the 10 kΩ potentiometer such that a nominal digital output code of 0000 0000 0000 (twos complement output) exists. Note that the zero trim should be decoupled and that the accuracy of the ±2.5 V reference signals will directly affect the offset.

Gain error may then be calibrated by adjusting the REF IN voltage. The REF IN voltage should be adjusted such that a +1 V input on V_{INA} results in the digital output code 01111 1111 1111 (twos complement output).

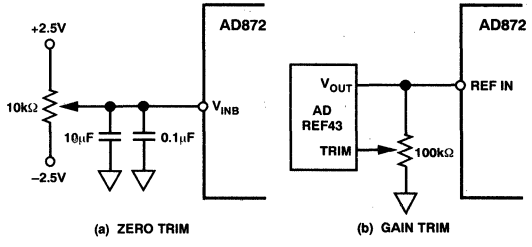

Figure 31. Zero and Gain Error Trims

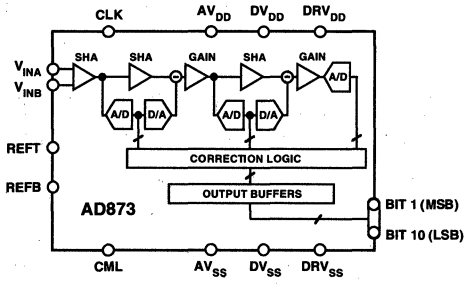
10-Bit 30 MSPS, 530 mW CMOS A/D Converter

AD873

FEATURES

Monolithic 10-Bit 30 MSPS A/D Converter
Power Dissipation: 530 mW
On-Chip Sample-and-Hold Amplifier
+5 V Single-Supply Operation
Signal-to-Noise Ratio f_{IN} = 3.58 MHz: 53 dB
Differential Nonlinearity: 0.8 LSB
Adjustable Reference Input
Differential Inputs
24-Pin "Skinny" DIP and 28-Pin SOIC

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD873 is a low power, single supply, CMOS 10-bit, 30 Msps analog-to-digital converter (ADC). The AD873 combines 10-bit video speed conversion with single-supply operation. The AD873's on-chip high impedance differential input sample-and-hold amplifier (SHA) allows direct conversion of video and HDTV bandwidth signals. The differential input SHA can be driven either differentially to reject high frequency noise coupled on the analog inputs or single ended with one input set to a dc offset level.

The AD873's dynamic performance is ideal in a variety of applications such as video enhancement, HDTV, ghost cancellation, medical imaging and high speed data acquisition. The AD873's 30 Msps sampling rate allows eight times oversampling of a standard NTSC video color subcarrier. The AD873's low power and single-supply operation are also suited for portable applications.

The AD873 is available over the commercial temperature range (0°C to +70°C) and is packaged in a space saving 24-pin plastic "skinny" DIP (JN) and 28-pin SOIC (JR).

PRODUCT HIGHLIGHTS

Sampling ADC: The differential input SHA eliminates the need for external buffering or sample-and-hold amplifiers.

Low Power: The AD873 has a typical power consumption of 500 mW. Reference ladder current is also low: 5 mA (typical), minimizing the reference power consumption.

Differential Nonlinearity: The AD873 features a typical DNL of 0.8 LSB. No missing codes guaranteed.

Single +5 V Supply Operation: The AD873 is designed to operate on a single +5 V supply.

Small Size: The AD873 is available in a space saving 24-pin "skinny" DIP and 28-pin SOIC.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

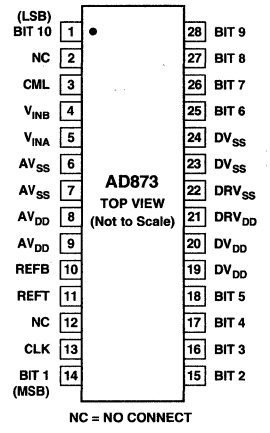
28-Pin SOIC



CAUTION

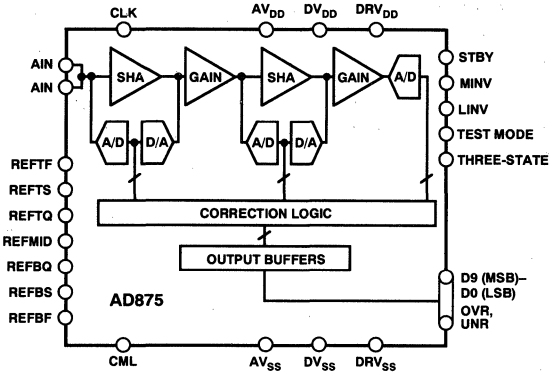
ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD873 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

10-Bit 15 MHz, 165 mW CMOS A/D Converter

AD875

FEATURES
CMOS 10-Bit 15 MHz A/D Converter
Low Power Dissipation: 185 mW
+5 V Single-Supply Operation
Differential Nonlinearity: 0.4 LSB
Guaranteed No Missing Codes
Power-Down (Standby) Mode: <50 mW
Three-State Outputs
Digital I/Os Compatible with +5 V or +3.3 V Logic
Adjustable Reference Input
Small Size: 48-Pin Thin Quad Flatpack (TQFP)

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD875 is a CMOS, low power 10-bit, 15 MHz analog-to-digital converter (ADC). The AD875 combines high speed 10-bit resolution and performance with low power and single-supply operation. By implementing a multistage pipelined architecture with output error correction logic, the AD875 offers accurate performance and guarantees no missing codes over the full operating temperature range. To minimize external voltage drops, the reference ladder top and bottom are provided with force and sense pins.

The AD875's digital I/Os can interface to either +5 V or +3.3 V logic. The AD875 can be placed into a standby mode of operation reducing the power below 50 mW. Digital output data can be placed in a high impedance state and is offered in a variety of formats, including straight binary and twos complement output. The AD875 also provides both underrange and overrange output bits, indicating when the analog input has exceeded the analog input range.

The AD875's speed, resolution and single-supply operation are ideally suited for a variety of applications in imaging, high speed data acquisition and communications. The AD875's low power and single supply operation are required for high speed portable applications. Its speed and resolution are ideally suited for charge coupled device (CCD) input systems such as color scanners, digital copiers, electronic still cameras and camcorders.

The AD875 is packaged in a space saving 48-pin thin quad flatpack (TQFP) and is specified over the commercial (0°C to +70°C) temperature range.

PRODUCT HIGHLIGHTS

Low Power—The AD875 at 185 mW consumes a fraction of the power of presently available 10-bit, video-speed converters. Power-down mode and single-supply operation further enhance its desirability in low power, battery operated applications such as electronic still cameras, camcorders and communication systems.

Superior Differential Nonlinearity Performance—The AD875's typical DNL performance is 0.4 LSB and a maximum of 0.8 LSBs for the 0 to 255 code range (ideal for imaging systems). No missing codes are guaranteed.

Very Small Package—The AD875 is available in a 48-pin surface mount, thin quad flatpack. The TQFP package is ideal for very tight, low headroom designs. The AD875 is available in tape-and-reel.

Digital I/O Functionality—The AD875 offers several digital features which allow output data formatting, fixed output test pattern generation to facilitate in-circuit testing, three-state output control and over/underrange indicators.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD875 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

DEFINITIONS OF SPECIFICATIONS

Integral Nonlinearity (INL)
Integral nonlinearity refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. The deviation is measured from the center of each particular code to the true straight line.

Differential Nonlinearity (DNL, No Missing Codes)
An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. It is often specified in terms of the resolution for which no missing codes (NMC) are guaranteed.

Offset Error
The first transition should occur at a level 1/2 LSB above "zero." Offset is defined as the deviation of the actual first code transition from that point.

Gain Error
The first code transition should occur for an analog value 1/2 LSB above nominal negative full scale. The last transition should occur for an analog value 1 1/2 LSB below the nominal positive full scale. Gain error is the deviation of the actual difference between first and last code transitions and the ideal difference between the first and last code transitions.

Pipeline Delay (Latency)
The number of clock cycles between conversion initiation and the associated output data being made available. New output data is provided every clock cycle.

Reference Force/Sense Offset
Resistance between the reference input and comparator input tap points causes offset errors. These errors can be nulled out by using the force-sense connection as shown in the Reference Input section.

THEORY OF OPERATION

The AD875 uses a pipelined multistage architecture to achieve high sample rate with low power. The multistage approach distributes the conversion over several smaller A/D sub-blocks, refining the conversion with progressively higher accuracy as it passes the results from stage to stage. As a consequence of the distributed conversion, the AD875 requires only a small fraction of the 1023 comparators that would be required in a more traditional 10-bit flash type A/D. A sample-and-hold (SHA) function within each of the stages permits the first stage to operate on a new sample of the input while the second and third stages operate on the two preceding samples. This "assembly line" operation on multiple samples, known as pipelining, allows higher throughput at the cost of some delay, referred to as latency. (See the output timing diagram.)

The detailed operation is as follows: the first stage makes a 4-bit estimate of the analog input voltage by means of the first stage A/D sub-block. The first stage estimate is converted to analog form by the first stage D/A and subtracted from the original input signal. The remainder, or residue, is the difference between the first stage estimate and the actual analog input. Next, the residue is amplified and passed to the second stage where another A/D sub-block makes a 4-bit estimate of its value. Again the analog version of the estimate is subtracted from the signal, and an even finer residue is generated. Finally, the A/D sub-block in the last stage measures the value of this second stage residue.

The A/D sub-blocks within each stage are actually 4-bit flash converters. Ideally 3 bits in the second and third stages would be sufficient for a 10-bit A/D. The additional bits allow for digital correction of errors in preceding stages, reducing the tolerances on the sub-block components and making a more robust A/D. The reference ladders for all three of these flash sub-blocks are wired in parallel and connected to the reference pins of the AD875.

Inside the AD875 all signals are processed differentially. This not only enhances the internal dynamic range of the components but provides a high level of noise immunity in a digital environment.

APPLYING THE AD875

DRIVING THE ANALOG INPUT

The high input resistance and low input capacitance features of the AD875 simplify the current and settling time demands placed on input drive circuitry. Figure 4 shows the equivalent input circuit of the AD875.

The full-scale input range is set by the voltage span, REFTF–REFBF (see "Driving the Reference" section). The recommended span should nominally be 2 V peak-to-peak. This span must remain bounded by the minimum and maximum input range (specified in the Analog Input section under DC Specifications). Some example input ranges are given in Table I.

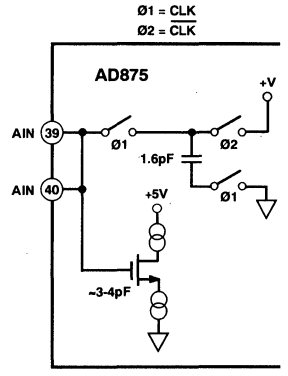

Figure 4. AD875 Equivalent Input Structure

Table I. Input Range Examples

−Full Scale = REFBF (V)	+Full Scale = REFTF (V)	Input Span (V)
+1.6	+3.6	+2.0
+2.0	+4.0	+2.0
+2.1	+4.1	+2.0

While the input impedance of the AD875 is quite high, the switched-capacitor input structure results in a small dynamic input current. In order to prevent gain variations as a result of the input current, maintaining a source impedance of less than or equal to 75 Ω is suggested (Figure 5). In general, a low drive impedance is suggested to minimize noise coupled on the AIN inputs.

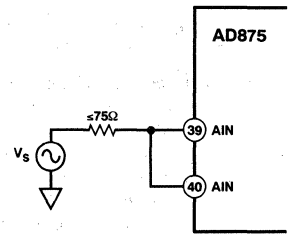

Figure 5. Simple AD875 Drive Requirements

For systems which must level shift a ground-referenced signal in order to comply with the input requirements of the AD875, a circuit like Figure 6 is recommended. The suggested op amp, an AD817 or AD818, is configured in inverting mode, where the ac gain of the input signal is −1. The amount of dc-level shifting is controlled by the dc voltage at the noninverting input of the op amp. The REFBF signal is attenuated by a resistive voltage divider and then multiplied by 2. In the case where REFBF = 1.6 V, the dc output level will be 2.6 V. The AD817 is a low cost, fast settling, single-supply op amp with a 29 MHz unity gain bandwidth. The AD818 is similar to the AD817 but has a 50 MHz unity gain bandwidth.

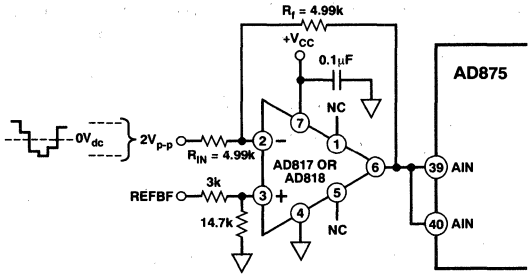

Figure 6. DC Level Shift with Gain of −1×

The AD875 samples the analog input voltage twice: once on the rising edge of the clock (CLK) and once on the falling edge. The first sample, taken on the rising edge, is used to perform a coarse estimate of the input. As indicated in Figure 7, the analog input voltage must be settled within V_{SE} (±16 mV) of its final value at this time and must remain within V_{SE} until the second sample has been taken. The second sample, taken on the falling edge of the clock, will determine the exact value digitized and should be accurate to within 10 bits (0.1%). Note that the actual sample points are delayed by t_{S1} and t_{S2}.

For applications where step input signals are expected (i.e., CCD or multiplexed outputs), the settling time of the input drive circuitry should be examined carefully. In most cases, the settling time requirements placed on the input amplifier are easily met by the AD817 or AD818. For higher speed operation, it may be necessary to use faster op amps such as the AD810 or AD811.

As a result of the AD875's settling requirements, there is a maximum slew rate limitation placed on the analog input signal. For applications using CCDs and other sampled analog systems, the AD875 can be used directly. However, for continuous signal applications, Figure 7 implies a maximum slew rate limitation on the analog input:

$$\textit{Slew Rate of Analog Input (maximum)} = \frac{16\ mV}{t_{CH}}\ (V/sec)$$

where t_{CH} is the "high" period of the sample clock in seconds, or one-half the full period when the clock is run with 50% duty cycle. For example, at 15 MHz clock rate, the maximum slew rate is about 0.48 V/μs. This corresponds to a maximum analog input frequency of 76 kHz when a full-scale (2 V peak-to-peak) sine wave is used. For input signals with higher slew rates, a sample-and-hold amplifier must be used for accurate digitization.

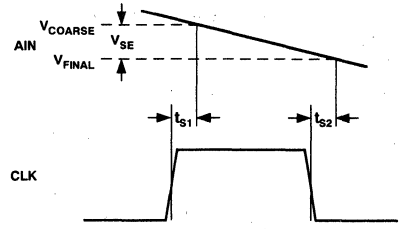

Figure 7. Analog Input Settling Requirement

REFERENCE INPUT

Driving the Reference Terminals

The AD875 requires an external reference on pins REFTF and REFBF. Reference sense pins REFTS and REFBS are also provided for Kelvin connections to minimize voltage drops due to external and internal wiring resistances. A resistor ladder nominally 400 Ω is connected internally between pins REFTF and REFBF.

The voltage drop across the internal resistor ladder determines the input span of the AD875. The driving voltages required at the REFTF and REFBF pins are nominally +4 V and +2 V respectively resulting in a 2 V input span. In order to maintain the requisite 2 V drop across the internal ladder, the external reference must be capable of typically providing 5 mA of dc current.

Transient current flows in and out of the REFTF and REFBF pins. Therefore, a low ac impedance is required at these terminals for proper operation. Bypassing each pin with suitable capacitive decoupling should effectively attenuate any transients. See the AD875 Evaluation Board Schematic for recommended values. Mid (REFMID) and quarter (REFTQ, REFBQ) ladder tap points are also available for additional decoupling if required. It is important to note that these tap points cannot be used to correct integral linearity as is sometimes done in a typical flash converters.

There are several reference configurations suitable for the AD875 depending on the application, desired performance and cost trade-offs. The simplest configuration, shown in Figure 8, utilizes a resistor string to generate the reference voltages from the converter's analog power supply. A 10 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor will provide adequate decoupling for both the REFTF and REFBF pins. The 0.1 μF capacitors should be physically located within 1cm of REFTF and REFBF. A 10 μF capacitor connected between REFTF and REFBF is also recommended for optimum performance. This reference configuration provides the lowest cost

solution but has several disadvantages including poor dc power supply rejection and poor accuracy due to the variability of the internal and external resistor values.

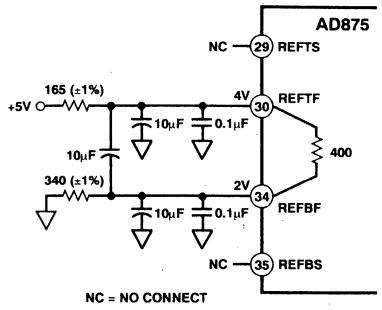

Figure 8. Low Cost Reference Circuit

A higher performance solution employs a voltage regulator to improve dc power supply rejection and absolute accuracy. Figure 9 shows a LM317 adjustable regulator configured to generate a 1.6 V output for REFBF. This output is also used to generate the 3.6 V REFTF signal by multiplying the REFBF signal by 2.25. Note that the AD817 op amp used to multiply REFBF has been compensated to ensure stability while driving the large capacitive load. The accuracy of this solution is limited by the external resistors and the initial accuracy of the reference.

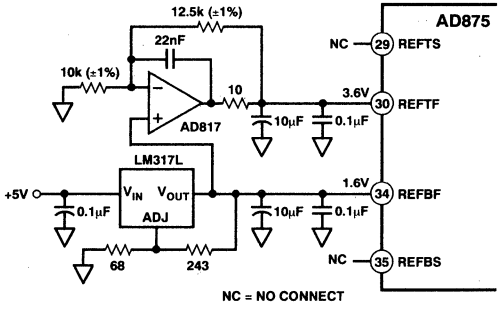

Figure 9. Reference Circuit with Good PSRR

For optimal performance, a force sense or Kelvin configuration can be used as shown in Figure 10. This circuit uses a high-accuracy reference (AD589) and a dual op amp (OP-295) to maintain accuracy and minimize voltage drops which are generated in the wire connections to the REFTF and REFBF inputs. The output of the AD589 is increased to 1.6 V and 3.6 V at the outputs of the op amps as required. Both op amps are compensated to maintain stability while driving the decoupling capacitors required at the REFTF and REFBF pins.

These outputs, being connected in a feedback loop, tend to cancel any errors caused by the voltage drops in the wires. Note that if the REFTS and REFBS are not used in a force sense configuration, they should be left unconnected and should not be connected to REFTF and REFBF.

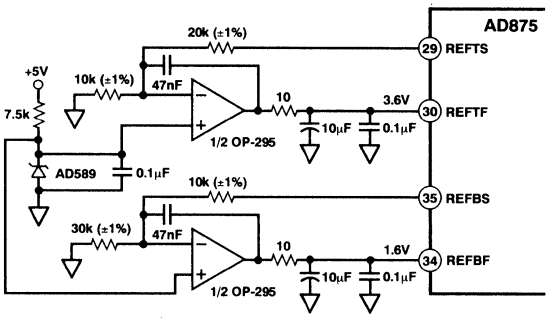

Figure 10. High Performance Reference Circuit Using Kelvin Connections

Like any high resolution converter, the layout and decoupling of the reference is critical. The actual voltage digitized by the AD875 is relative to the reference voltages. In Figure 11, for example, the reference returns and the bypass capacitors are connected to the shield of the incoming analog signal. Disturbances in the ground of the analog input, which will be common-mode to the REFTF, REFBF, and AIN pins because of the common ground, are effectively removed by the AD875's high common-mode rejection.

High frequency noise sources, V_{N1} and V_{N2}, are shunted to ground by decoupling capacitors. Any voltage drops between the analog input ground and the reference bypassing points will be treated as input signals by the converter via the reference inputs. Consequently, the reference decoupling capacitors should be connected to the same analog ground point used to define the analog input voltage. (For further suggestions, see the "Grounding and Layout Rules" section of the data sheet.)

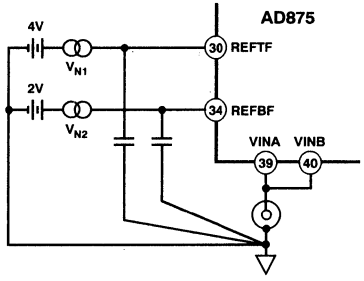

Figure 11. Recommended Bypassing for the Reference Inputs

CLOCK INPUT

The AD875 clock input is buffered internally with an inverter powered from the DRV_{DD} pin. This feature allows the AD875 to accommodate either +5 V or +3.3 V CMOS logic input signal swings with the input threshold for the CLK pin nominally at $DRV_{DD}/2$.

The AD875's pipelined architecture operates on both rising and falling edges of the input clock. To minimize duty cycle variations the recommended logic family to drive the clock input is high speed CMOS (HC/HCT) logic. HCMOS logic provides both symmetrical voltage threshold levels and sufficient rise and fall times to support 15 MHz operation. The AD875's minimum

clock half cycle may necessitate the use of an external divide-by-two circuit as shown in Figure 12.

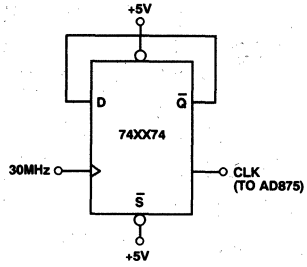

Figure 12. Divide-By-Two Clock Input Circuit

The AD875 is designed to support a conversion rate of 15 MHz; running the part at slightly faster clock rates may be possible, although at reduced performance levels. Conversely, some slight performance improvements might be realized by clocking the AD875 at slower clock rates.

The power dissipated by the correction logic and output buffers is largely proportional to the clock frequency; running at reduced clock rates provides a reduction in power consumption. Figure 13 illustrates this trade-off.

DIGITAL INPUTS AND OUTPUTS

Each of the AD875's digital control inputs, MINV, LINV, TEST MODE, THREE-STATE, and STBY is buffered with an inverter powered from the DRV_{DD} supply pins. With DRV_{DD} set to +5 V all digital inputs readily interface with 5 V CMOS logic. For interfacing with lower voltage CMOS logic, DRV_{DD} can be set to 3.3 V effectively lowering the nominal input threshold of all digital inputs to 3.3 V/2 = 1.65 V.

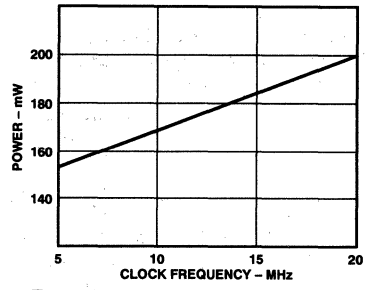

Figure 13. Typical Power Dissipation vs. Clock Frequency

The AD875 provides several convenient digital input pins for controlling the converter output format. By utilizing digital input pins MINV and LINV, three digital output formats are possible: binary, twos complement, and ones complement.

Another element of digital functionality is provided with the TEST MODE pin. To facilitate in-circuit testing of the digital portion of your application, a fixed digital pattern controlled by a digital input is available. For TEST MODE = LOW, an alternating 1010101010 pattern is established. This pattern is further manipulated when used in conjunction with the LINV and MINV pins (see Output Data Format, Table II below).

Table II. Output Data Format

Z – High Impedance; X – Don't Care; ? – Determined By AIN.

Also, a sleep mode feature is provided such that for STBY = HIGH and the clock disabled, the static power of the AD875 will drop below 50 mW. The AD875 reaches rated accuracy 4 clock cycles after STBY is brought LOW and the clock is started.

DIGITAL OUTPUTS

Each of the on-chip buffers for the AD875 output bits (D0–D9, OVR, UNR) is powered from the DRV_{DD} supply pins, separate from AV_{DD} or DV_{DD}. The output drivers are sized to handle a variety of logic families while minimizing the amount of glitch energy generated. In all cases, a fan-out of one is recommended to keep the capacitive load on the output data bits below the specified 20 pF level.

For DRV_{DD} = 5 V, the AD875 output signal swing is compatible with both high speed CMOS and TTL logic families. For TTL, the AD875 on-chip, output drivers were designed to support several of the high speed TTL families (F, AS, S). For applications where the clock rate is below 15 MHz, other TTL families may be appropriate. For interfacing with lower voltage CMOS logic, the AD875 sustains 15 MHz operation with DRV_{DD} = 3.3 V. In all cases, check your logic family data sheets for compatibility with the AD875 Digital Specification table.

THREE-STATE OUTPUTS

The digital outputs of the AD875 can be placed in a high impedance state by setting the THREE-STATE pin to HIGH. This feature is provided to facilitate in-circuit testing or evaluation. Note that this function is not intended for enabling/disabling the ADC outputs from a bus at 15 MHz. Also, to avoid corruption of the sampled analog signal during conversion (three clock cycles), it is highly recommended that the AD875 outputs be enabled on the bus prior to the first sampling. For the purpose of budgetary timing, the maximum access and float delay times (t_{DD}, t_{HL} shown in Figure 14) for the AD875 are 150 ns.

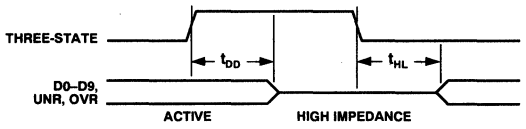

Figure 14. High Impedance Output Timing Diagram

OUT OF RANGE

As Table II indicates, an Underrange (UNR) or Overrange (OVR) condition exists when the analog input voltage is beyond the input range (nominally +2 V to +4 V) of the converter. UNR (Pin 46) is set LOW when the analog input voltage is within the analog input range. UNR is set HIGH (after accounting for pipeline latency) and will remain HIGH when the analog input voltage is less than the input range by 1/2 LSB from the center of the negative full-scale output code. OVR (Pin 47) is set LOW when the analog input voltage is within the analog input range. OVR is set HIGH (after accounting for pipeline latency) and will remain HIGH when the analog input voltage is greater than the input range by 1/2 LSB from the center of the positive full-scale output code.

GROUNDING AND LAYOUT RULES

As is the case for any high performance device, proper grounding and layout techniques are essential in achieving optimal performance. The analog and digital grounds on the AD875 have been separated to optimize the management of return currents in a system. It is recommended that a 4-layer printed circuit board (PCB) which employs a ground plane and power planes be used with the AD875. The use of ground and power planes offers distinct advantages:

1. The minimization of the loop area encompassed by a signal and its return path.
2. The minimization of the impedance associated with ground and power paths.
3. The inherent distributed capacitor formed by the power plane, PCB insulation, and ground plane.

These characteristics result in both a reduction of electromagnetic interference (EMI) and an overall improvement in performance.

It is important to design a layout which prevents noise from coupling onto the input signal. Digital signals should not be run in parallel with the input signal traces and should be routed away from the input circuitry.

Separate analog and digital grounds should be joined together directly under the AD875. A solid ground plane under the AD875 is also acceptable if care is taken in the management of the power and ground return currents. A general "rule-of-thumb" for mixed signal layouts dictates that the return currents from digital circuitry should not pass through critical analog circuitry.

POWER SUPPLY DECOUPLING

The analog and digital supplies of the AD875 have been separated to prevent the typically large transients associated with digital circuitry from coupling into the analog supply (AV_{DD}).

The digital supplies have also been separated into DRV_{DD} and DV_{DD}. The DRV_{DD} pins provide power for the digital I/O's of the AD875 and are likely to contain high energy transients. Each power supply pin should be decoupled with a 0.1 μF capacitor located as close to the pin as possible. For optimal performance, surface-mount capacitors are recommended. The inductance associated with the leads of through-hole ceramic capacitors typically render them ineffective at higher frequencies. A *complete* system will also incorporate tantalum capacitors in the 10–100 μF range to decouple low frequency noise and ferrite beads to limit high frequency noise.

APPLICATIONS

IMAGING SYSTEM OVERVIEW

While the specifics of a particular imaging system will vary, most architectures will employ some or all of the building blocks shown in Figure 15. The image sensor, often a charged-coupled device (CCD), transforms light to electrical output. The resultant pixel stream is conditioned by a clamp/sample-hold circuit which is sometimes referred to as a correlated double sampler (CDS). A gain block sets signal levels which maximize the utilization of the dynamic range of the A/D converter. DC restoration is often used to remove any static dc errors which may accumulate over time and temperature. The digitized signal is then processed by the application specific digital signal processor.

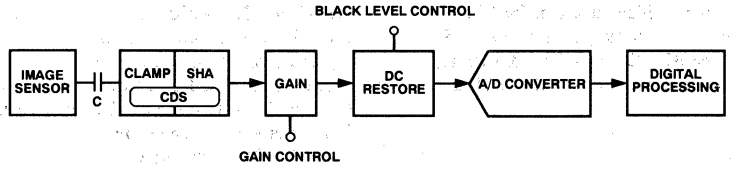

Figure 15. Typical Imaging System Block Diagram

For optimum performance the CDS is tailored to the sensor output characteristics. When used in conjunction with a CCD, the CDS acts to remove low frequency signal variations, kT/C noise, and other noise components, all of which are artifacts generated by the CCD. The output signal from the CCD is characterized by a series of pixels, each containing both a reset level and the actual video data. Aside from the various noise components, the video data is essentially a stream of stepped dc signals. This pixel stream from the CCD is then ac-coupled through a capacitor to a switch (contained within the CDS block).

This switch, in turn, is connected to a clamp reference voltage. The switch is closed during the reset portion of each pixel. As a result, the difference between the reset level of each pixel and the clamp reference voltage is stored on the coupling capacitor. When the switch is opened, the dc voltage stored on the coupling capacitor sets the dc level for the pixel stream. The video portion of each pixel is then sampled and held using traditional sample/hold (SHA) architectures. Since the CCD noise sources are correlated between the reset and video portions of the pixel stream, and the output of the SHA represents the difference between these two levels, the noise is effectively eliminated.

The output of the CDS will generally require some form of gain control in order to maximize the full-scale input range of the A/D converter. In some applications, a fixed gain may be adequate while in many applications such as camcorders, variable gain control is used to automatically account for variations in scene brightness. Gain control can be achieved using analog or digital techniques and often times must be able to respond at a rate equivalent to the pixel rate. Gilbert multiplier cells and multiplying D/As are two common circuits used for the gain block.

The dc restore block acts to set the final dc level of the signal before digitization by the A/D converter. A fixed voltage level (equivalent to the black level or negative full scale) generated by the CCD is sampled by the dc restoration circuit usually at the beginning or end of a "scan line." Any difference between the sampled black level and the desired negative full scale is removed either by a servo loop or corrected digitally. To maximize the use of the A/D's input range, the error must be removed prior to the A/D. This is generally accomplished by a high dc-gain feedback path which servos any error detected at the output. The dc restoration effectively removes dc level shifts which may occur as a result of long-term parameter shifts such as component drift and temperature variations.

The main criterion for choosing the A/D converter is generally based on resolution and speed. Resolution affects the signals-to-noise ratio of the system, dictates the maximum digital dynamic range of the image, and is a consideration for round-off errors produced in the digital signal processing. The speed of the A/D converter is related to the number of pixel elements and the pixel output rate of the particular image sensor. Multichannel systems may multiplex more than one pixel stream into a single A/D, thus requiring faster conversion rates. Similarly, area CCDs (CCDs which capture video information in two dimensions) operate at higher rates than linear (one dimensional) CCDs.

MULTICHANNEL IMAGE ACQUISITION SYSTEM

The AD875's fast conversion rate combined with the AD783 sample/hold amplifiers (SHAs) and the AD9300 high speed multiplexer can be used to construct an analog front-end capable of acquiring and digitizing three or more analog signals at a rate of 1 Msps. Figure 16 shows a typical circuit which employs three AD783s capable of acquiring a 2 V p-p step input to 10-bit accuracy in less than 350 ns.

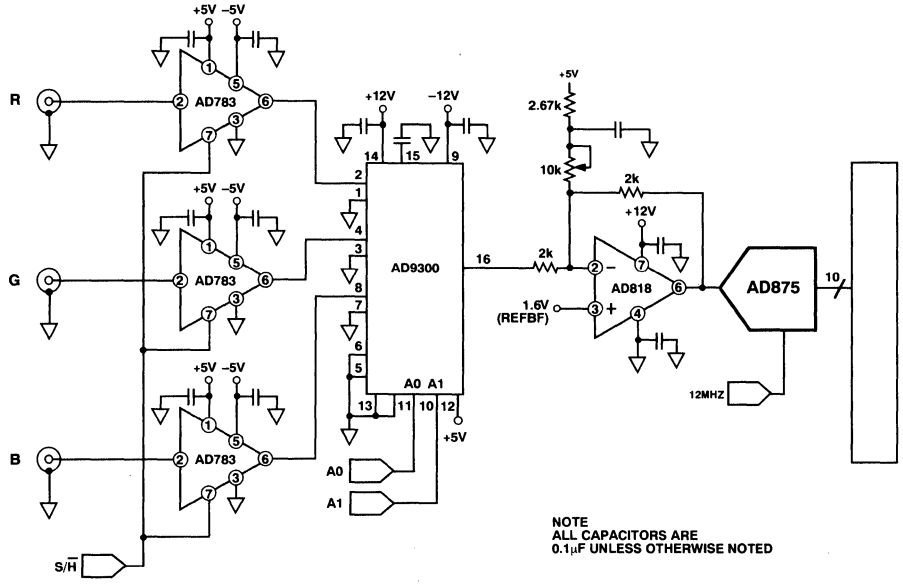

Figure 16. Multichannel Image Acquisition System

Referring to the timing diagram in Figure 17, the three analog inputs are simultaneously sampled on the falling edge of S/$\overline{H}$. After allowing the SHAs to settle (250 ns), the R channel is digitized at the conversion rate of 12 MHz (83.3 ns). Next, the MUX is switched to the G channel, allowed to settle (83.3 ns), and digitized. The B channel is digitized similarly. While the B channel is converted, the R channel data becomes available at the output of the AD875 (due to the pipelined latency). The rising edges of the signals RDAV, GDAV, and BDAV are the signals which indicate when valid data is available at the output of the A/D converter.

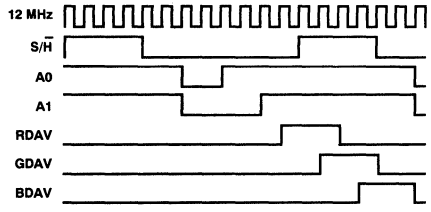

Figure 17. Timing Diagram for Figure 16

HIGH SPEED SAMPLE-AND-HOLD AMPLIFIER (SHA)

A sample-hold amplifier is often needed as part of a correlated double sampler or when high bandwidth inputs such as video signals are to be converted by the AD875. For fast, precise sampling required for video signals, an integrated solution such as the AD9101 track-and-hold amplifier is suggested for optimum performance. However, the requirements of many 10-bit imaging systems can be achieved using a SHA architecture similar to the one shown in Figure 18. This discrete SHA can accurately acquire a 1 V input step within 1 mV accuracy in less than 200 ns. Hold-mode settling within 1 mV is typically less than 50 ns. The resultant throughput rate is 3.3 Msps.

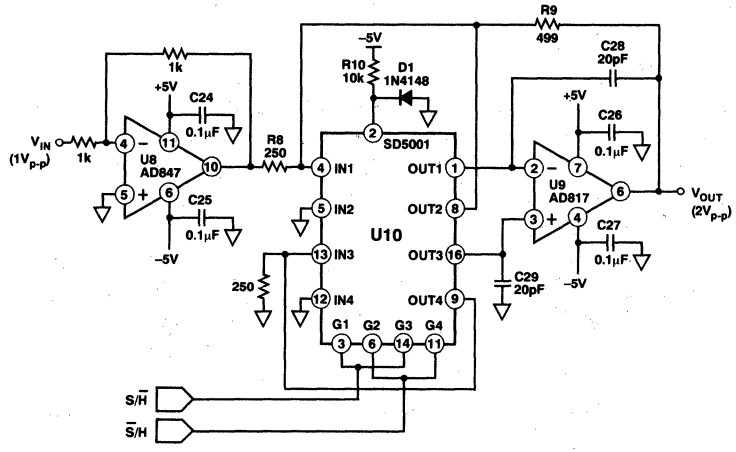

Figure 18. High Speed Discrete SHA

CIRCUIT DESCRIPTION

The discrete SHA shown in Figure 13 is a closed-loop, noninverting architecture that accepts 1 V p-p inputs. The overall gain of the SHA is +2 in order to accommodate the 2 V input span of the AD875. The AD847, with 0.1% settling time of 65 ns, is the suggested input buffer to the SHA. The circuit also employs an SD5001 that contains four ultrahigh speed DMOS switches (Q1–Q4). The low cost, fast settling time and high CMRR of the AD817 op amp are critical features necessary for optimal performance and economy.

In sample mode, Q1 and Q3 of the SD5001 are closed (Q2 and Q4 are open). C28 is charged to the input voltage level at a rate primarily determined by the time constant, R9 × C28, and the gain (2×). Simultaneously, C29 is connected to ground through a 250 Ω resistor. If C28 is equal to C29, charge injection from Q1 will be approximately equal to charge injection form Q3 based on the symmetry of the circuit and the inherent matching of the switch capacitance. The resultant pedestal errors appear as a common-mode signal to the AD817 and are approximately canceled from the differential architecture.

In hold mode, Q2 and Q4 are closed (Q1 and Q3 are open) to reduce feedthrough. The AD817 buffers the voltage held on C28 and settles within the requisite 1 mV within 50 ns. The output of the AD817 must then be level-shifted in order to interface with the AD875 input span requirements. Throughput rates greater than 3.3 Msps using this architecture are limited by the R_{ON} of the SD5001. Faster sample rates require open-loop architectures or diode-bridge switching in order to reduce the on-resistance.

TIMING DESCRIPTION

Figure 19 shows the timing requirements for the discrete SHA. The complementary S/$\overline{H}$ inputs are HCMOS-compatible although larger gate voltages will improve performance slightly by lowering the on resistances of the DMOS switches. The conversion is started as soon as the output of the SHA has settled within 16 mV of its final value.

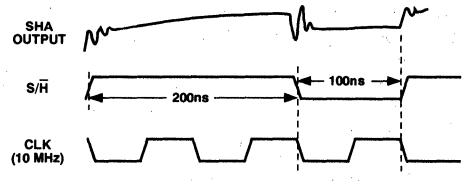

Figure 19. Timing Diagram for Discrete SHA

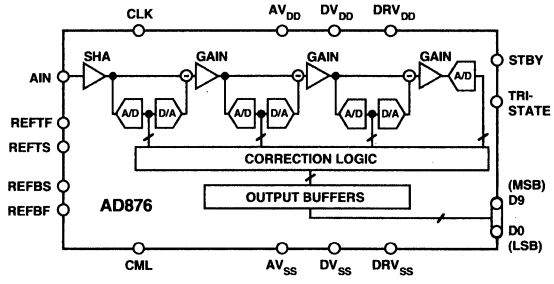
10-Bit 20 MSPS, 140 mW CMOS A/D Converter

AD876

FEATURES

CMOS 10-Bit 20 MSPS Sampling A/D Converter
Power Dissipation: 140 mW
+5 V Single Supply Operation
Differential Nonlinearity: 0.5 LSB
Guaranteed No Missing Codes
Power Down (Stand-By) Mode
Three-State Outputs
Digital I/Os Compatible with +5 V or +3.3 V Logic
Adjustable Reference Input
Small Size: 28-Pin SOIC or 48-Pin Thin Quad Flatpack (TQFP)

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD876 is a CMOS, 140 mW, 10-bit, 20 Msps analog-to-digital converter (ADC). The AD876 has an on-chip input sample-and-hold amplifier. The AD876's digital I/Os interface to either +5 V or +3.3 V logic. By implementing a multistage pipelined architecture with output error correction logic, the AD876 offers accurate performance and guarantees no missing codes over the full operating temperature range. To minimize external voltage drops, the reference ladder top and bottom are provided with force and sense pins.

The AD876 can be placed into a standby mode of operation reducing the power below 50 mW. Digital output data can be placed in a high impedance state and is offered in straight binary output.

The AD876's speed, resolution and single supply operation are ideally suited for a variety of applications in video, multimedia, imaging, high speed data acquisition and communications. The AD876's low power and single supply operation are required for high speed portable applications. Its speed and resolution are ideally suited for charge coupled device (CCD) input systems such as color scanners, digital copiers, electronic still cameras and camcorders.

The AD876 is packaged in a space saving 28-pin SOIC and 48-pin thin quad flatpack (TQFP) and is specified over the commercial (0°C to +70°C) temperature range.

PRODUCT HIGHLIGHTS

Low Power: The AD876 at 140 mW consumes a fraction of the power of presently available 10-bit, video-speed converters. Power-down mode and single supply operation further enhance its desirability in low power, battery operated applications such as electronic still cameras, camcorders and communication systems.

Very Small Package: The AD876 is available in both a 28-pin SOIC and 48-pin surface mount, thin quad flat package. The TQFP package is ideal for very tight, low headroom designs.

Digital I/O Functionality: The AD876 offers three-state output control.

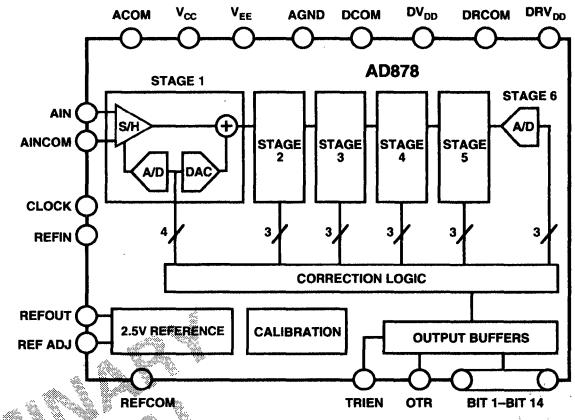
FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD878 is a monolithic 14-bit, 2.2 Msps analog-to-digital converter with an on-chip, high performance sample-and-hold amplifier and voltage reference. The AD878 uses a multistage pipelined architecture with factory programmed calibration circuitry and output error correction logic to provide 14-bit accuracy at 2.2 Msps data rates. The AD878 combines a merged high speed bipolar/CMOS process and a novel architecture to achieve the resolution and speed of hybrid implementations at a fraction of the power consumption. Additionally, the greater reliability of monolithic construction offers improved system reliability and lower costs than hybrid designs.

The high input impedance, fast-settling input sample-and-hold (S/H) amplifier is well suited for both multiplexed systems that switch negative to positive full-scale voltage levels in successive channels and sampling single-channel inputs at frequencies up to the Nyquist rate. The AD878's wideband input combined with the power and cost savings over previously available hybrids will allow new design opportunities in communications, imaging and medical applications. The AD878 provides both reference output and reference input pins, allowing the on-board reference to serve as a system reference. An external reference can also be substituted to suit the dc accuracy and temperature drift requirements of the application. A single clock input is used to control all internal conversion cycles. The digital output data is presented in binary output format. An out-of-range signal indicates an overflow condition. It can be used with the most significant bit to determine low or high overflow.

The AD878 is fabricated on Analog Devices' ABCMOS process which utilizes high speed bipolar and CMOS transistors on a single chip. High speed, precision analog circuits are now combined with high density logic circuits.

The AD878 is packaged in a 44-pin plastic leaded chip carrier (PLCC) package and is specified for operation from 0°C to +70°C and –40°C to +85°C.

PRODUCT HIGHLIGHTS

The AD878 offers a complete single-chip sampling 14-bit, 2.2 Msps analog-to-digital conversion function in a 44-pin PLCC surface mount package.

Low Power: The AD878 at 650 mW max consumes a fraction of the power of presently available hybrids.

On-Chip Sample-and-Hold (S/H): The high impedance S/H input eliminates the need for external buffers.

Out of Range (OTR): The OTR output bit indicates when the input signal is beyond the AD878's input range.

Ease-of-Use: The AD878 is complete with S/H and voltage reference.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Exposure to absolute maximum ratings for extended periods may effect device reliability.

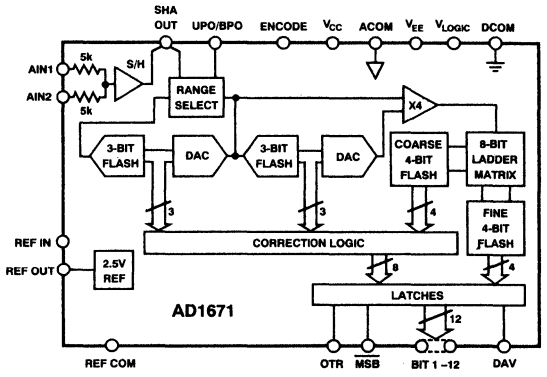
Complete 12-Bit 1.25 MSPS Monolithic A/D Converter

AD1671

FEATURES

- **Conversion Time: 800 ns**
- **1.25 MHz Throughput Rate**
- **Complete: On-Chip Sample-and-Hold Amplifier and Voltage Reference**
- **Low Power Dissipation: 570 mW**
- **No Missing Codes Guaranteed**
- **Signal-to-Noise Plus Distortion Ratio**
  f_{IN} = 100 kHz: 70 dB
- **Pin Configurable Input Voltage Ranges**
- **Twos Complement or Offset Binary Output Data**
- **28-Pin DIP and 28-Pin Surface Mount Package**
- **Out of Range Indicator**

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1671 is a monolithic 12-bit, 1.25 MSPS analog-to-digital converter with an on-board, high performance sample-and-hold amplifier (SHA) and voltage reference. The AD1671 guarantees no missing codes over the full operating temperature range. The combination of a merged high speed bipolar/CMOS process and a novel architecture results in a combination of speed and power consumption far superior to previously available hybrid implementations. Additionally, the greater reliability of monolithic construction offers improved system reliability and lower costs than hybrid designs.

The fast settling input SHA is equally suited for both multiplexed systems that switch negative to positive full-scale voltage levels in successive channels and sampling inputs at frequencies up to and beyond the Nyquist rate. The AD1671 provides both reference output and reference input pins, allowing the on-board reference to serve as a system reference. An external reference can also be chosen to suit the dc accuracy and temperature drift requirements of the application.

The AD1671 uses a subranging flash conversion technique, with digital error correction for possible errors introduced in the first part of the conversion cycle. An on-chip timing generator provides strobe pulses for each of the four internal flash cycles. A single ENCODE pulse is used to control the converter. The digital output data is presented in twos complement or offset binary output format. An out-of-range signal indicates an overflow condition. It can be used with the most significant bit to determine low or high overflow.

The performance of the AD1671 is made possible by using high speed, low noise bipolar circuitry in the linear sections and low power CMOS for the logic sections. Analog Devices' ABCMOS-1 process provides both high speed bipolar and 2-micron CMOS devices on a single chip. Laser trimmed thin-film resistors are used to provide accuracy and temperature stability.

The AD1671 is available in two performance grades and three temperature ranges. The AD1671J and K grades are available over the 0°C to +70°C temperature range. The AD1671A grade is available over the −40°C to +85°C temperature range. The AD1671S grade is available over the −55°C to +125°C temperature range.

PRODUCT HIGHLIGHTS

The AD1671 offers a complete single chip sampling 12-bit, 1.25 MSPS analog-to-digital conversion function in a 28-pin package.

The AD1671 at 570 mW consumes a fraction of the power of currently available hybrids.

An OUT OF RANGE output bit indicates when the input signal is beyond the AD1671's input range.

Input signal ranges are 0 V to +5 V unipolar or ±5 V bipolar, selected by pin strapping, with an input resistance of 10 kΩ. The input signal range can also be pin strapped for 0 V to +2.5 V unipolar or ±2.5 V bipolar with an input resistance of 10 MΩ.

Output data is available in unipolar, bipolar offset or bipolar twos complement binary format.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

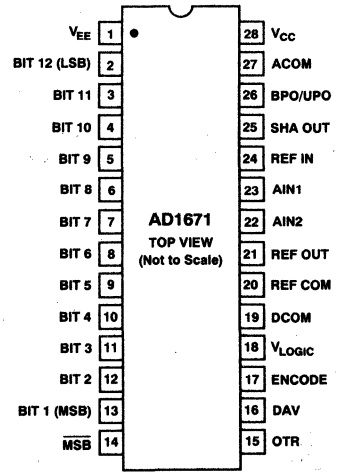
PIN DESCRIPTION

Symbol	Pin No.	Type	Name and Function
ACOM	27	P	Analog Ground.
AIN	22, 23	AI	Analog Inputs, AIN1 and AIN2. The AD1671 can be pin strapped for four input ranges: Range / Pin Strap / Signal Input 0 to +2.5 V, ±2.5 V / Connect AIN1 to AIN2 / AIN1 or AIN2 0 to +5 V, ±5 V / Connect AIN1 or AIN2 to ACOM / AIN1 or AIN2
BIT 1 (MSB)	13	DO	Most Significant Bit.
BIT 2–BIT 11	12–3	DO	Data Bits 2 through 11.
BIT 12 (LSB)	2	DO	Least Significant Bit.
BPO/UPO	26	AI	Bipolar or Unipolar Configuration Pin. See section on Input Range Connections for details.
DAV	16	DO	Data Available Output. The rising edge of DAV indicates an end of conversion and can be used to latch current data into an external register. The falling edge of DAV can be used to latch previous data into an external register.
DCOM	19	P	Digital Ground.
ENCODE	17	DI	The analog input is sampled on the rising edge of ENCODE.
$\overline{\text{MSB}}$	14	DO	Inverted Most Significant Bit. Provides twos complement output data format.
OTR	15	DO	Out of Range is Active HIGH when the analog input is out of range. See Output Data Format, Table III.
REF COM	20	AI	REF COM is the internal reference ground pin. REF COM should be connected as indicated in the Grounding and Decoupling Rules and Optional External Reference Connection Sections.
REF IN	24	AI	REF IN is the external 2.5 V reference input.
REF OUT	21	AO	REF OUT is the internal 2.5 V reference output.
SHA OUT	25	AO	No Connect for bipolar input ranges. Connect SHA OUT to BPO/UPO for unipolar input ranges.
V_{CC}	28	P	+5 V Analog Power.
V_{EE}	1	P	−5 V Analog Power.
V_{LOGIC}	18	P	+5 V Digital Power.

TYPE: AI = Analog Input; AO = Analog Output; DI = Digital Input; DO = Digital Output; P = Power.

PIN CONFIGURATION



CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ABSOLUTE MAXIMUM RATINGS*

Parameter	With Respect to	Min	Max	Units
V_{CC}	ACOM	−0.5	+6.5	Volts

DEFINITIONS OF SPECIFICATIONS

INTEGRAL NONLINEARITY (INL)

Integral nonlinearity refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB (1.22 mV for a 10 V span) before the first code transition (all zeros to only the LSB on). "Full-scale" is defined as a level 1 1/2 LSB beyond the last code transition (to all ones). The deviation is measured from the low side transition of each particular code to the true straight line.

DIFFERENTIAL LINEARITY ERROR (NO MISSING CODES)

An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from the ideal value. Thus every code has a finite width. Guaranteed no missing codes to 11 or 12-bit resolution indicates that all 2048 and 4096 codes, respectively, must be present over all operating ranges. No missing codes to 11 bits (in the case of a 12-bit resolution ADC) also means that no two consecutive codes are missing.

UNIPOLAR OFFSET

The first transition should occur at a level 1/2 LSB above analog common. Unipolar offset is defined as the deviation of the actual from that point. This offset can be adjusted as discussed later. The unipolar offset temperature coefficient specifies the maximum change of the transition point over temperature, with or without external adjustments.

BIPOLAR ZERO

In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2 LSB below analog common. The bipolar offset error and temperature coefficient specify the initial deviation and maximum change in the error over temperature.

GAIN ERROR

The last transition (from 1111 1111 1110 to 1111 1111 1111) should occur for an analog value 1 1/2 LSB below the nominal full scale (4.9963 volts for 5.000 volts full scale). The gain error is the deviation of the actual level at the last transition from the ideal level. The gain error can be adjusted to zero as shown in Figures 4 through 7.

TEMPERATURE COEFFICIENTS

The temperature coefficients for unipolar offset, bipolar zero and gain error specify the maximum change from the initial (+25°C) value to the value at T_{MIN} or T_{MAX}.

POWER SUPPLY REJECTION

One of the effects of power supply error on the performance of the device will be a small change in gain. The specifications show the maximum full-scale change from the initial value with the supplies at the various limits.

DYNAMIC SPECIFICATIONS

SIGNAL-TO-NOISE PLUS DISTORTION (S/N+D) RATIO

S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

EFFECTIVE NUMBER OF BITS (ENOB)

ENOB is calculated from the expression (S/N+D) = 6.02N + 1.76 dB, where N is equal to the effective number of bits.

TOTAL HARMONIC DISTORTION (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

INTERMODULATION DISTORTION (IMD)

With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products of order (m+n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb), and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (2fb − fa). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sum is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

PEAK SPURIOUS OR PEAK HARMONIC COMPONENT

The peak spurious or peak harmonic component is the largest spectral component, excluding the input signal and dc. This

value is expressed in decibels relative to the rms value of a full-scale input signal.

APERTURE DELAY

Aperture delay is the difference between the switch delay and the analog delay of the SHA. This delay represents the point in time, relative to the rising edge of ENCODE input, that the analog input is sampled.

APERTURE JITTER

Aperture jitter is the variation in aperture delay for successive samples.

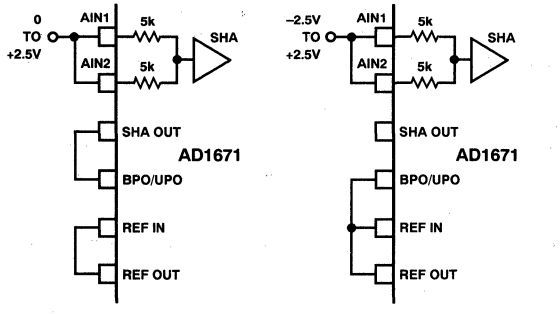
FULL POWER BANDWIDTH

The input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

THEORY OF OPERATION

The AD1671 uses a successive subranging architecture. The analog-to-digital conversion takes place in four independent steps or flashes. The sampled analog input signal is subranged to an intermediate residue voltage for the final 12-bit result by utilizing multiple flashes with subtraction DACs (see the AD1671 functional block diagram).

The AD1671 can be configured to operate with unipolar (0 V to +5 V, 0 V to +2.5 V) or bipolar (±5 V, ±2.5 V) inputs by connecting AIN (Pins 22, 23), SHA OUT (Pin 25) and BPO/UPO (Pin 26) as shown in Figure 2.



a. 0 V to +2.5 V Input Range *b. ±2.5 V Input Range*

c. 0 V to +5 V Input Range *d. ±5 V Input Range*

Figure 2. AD1671 Input Range Connections

The AD1671 conversion cycle begins by simply providing an active HIGH level on the ENCODE pin (Pin 17). The rising edge of the ENCODE pulse starts the conversion. The falling edge of the ENCODE pulse is specified to operate within a window of time, less than 50 ns after the rising edge of ENCODE or after the falling edge of DAV. The time window prevents digitally coupled noise from being introduced during the final stages of conversion. An internal timing generator circuit accurately controls SHA, flash and DAC timing.

Upon receipt of an ENCODE command the input voltage is held by the front-end SHA and the first 3-bit flash converts the analog input voltage. The 3-bit result is passed to a correction logic register and a segmented current output DAC. The DAC output is connected through a resistor (within the Range/Span Select Block) to SHA OUT. A residue voltage is created by subtracting the DAC output from SHA OUT, which is less than one eighth of the full-scale analog input. The second flash has an input range that is configured with one bit of overlap with the previous DAC. The overlap allows for errors during the flash conversion. The first residue voltage is connected to the second 3-bit flash and to the noninverting input of a high speed, differential, gain of eight amplifier. The second flash result is passed to the correction logic register and to the second segmented current output DAC. The output of the second DAC is connected to the inverting input of the differential amplifier. The differential amplifier output is connected to a two-step, backend, 8-bit flash. This 8-bit flash consists of coarse and fine flash converters. The result of the coarse 4-bit flash converter, also configured to overlap one bit of DAC 2, is connected to the correction logic register and selects one of 16 resistors from which the fine 4-bit flash will establish its span voltage. The fine 4-bit flash is connected directly to the output latches.

The internal timing generator automatically places the SHA into the acquire mode when DAV goes LOW. Upon completion of conversion (when DAV is set HIGH), the SHA has acquired the analog input to the specified level of accuracy and will remain in the sample mode until the next ENCODE command.

The AD1671 will flag an out-of-range condition when the input voltage exceeds the analog input range. OTR (Pin 15) is active HIGH when an out-of-range high or low condition exists. Bits 1–12 are HIGH when the analog input voltage is greater than the selected input range and LOW when the analog input is less than the selected input range.

AD1671 DYNAMIC PERFORMANCE

The AD1671 is specified for dc and dynamic performance. A sampling converter's dynamic performance reflects both quantizer and sample-and-hold amplifier (SHA) performance. Quantizer nonlinearities, such as INL and DNL, can degrade dynamic performance. However, a SHA is the critical element which has to accurately sample fast slewing analog input signals. The AD1671's high performance, low noise, patented on-chip SHA minimizes distortion and noise specifications. Nonlinearities are minimized by using a fast slewing, low noise architecture and subregulation of the sampling switch to provide constant offsets (therefore reducing input signal dependent nonlinearities).

Figure 3 is a typical 2k point Fast Fourier Transform (FFT) plot of a 100 kHz input signal sampled at 1 MHz. The fundamental amplitude is set at −0.5 dB to avoid input signal clipping of offset or gain errors. Note the total harmonic distortion is approximately −81 dB, signal to noise plus distortion is 71 dB and the spurious free dynamic range is 84 dB.

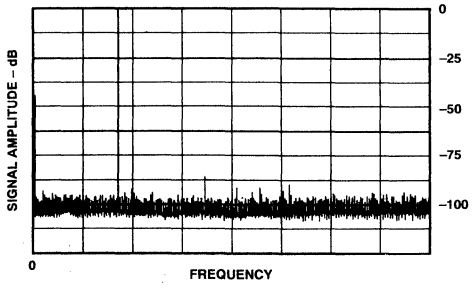


Figure 3. AD1671 FFT Plot, f_{IN} = 100 kHz, f_{SAMPLE} = 1 MHz

Figure 4 plots both S/(N+D) and Effective Number of Bits (ENOB) for a 100 kHz input signal sampled from 666 kHz to 1.25 MHz.

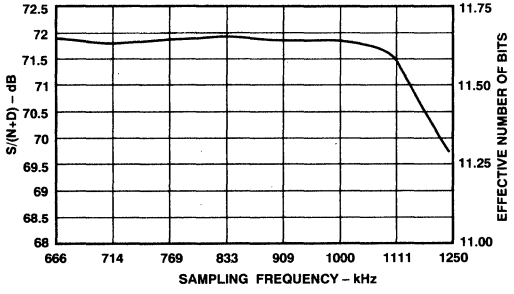

Figure 4. S/(N+D) vs. Sampling Frequency, f_{IN} = 100 kHz

Figure 5 is a THD plot for a full-scale 100 kHz input signal with the sample frequency swept from 666 kHz to 1.25 MHz.

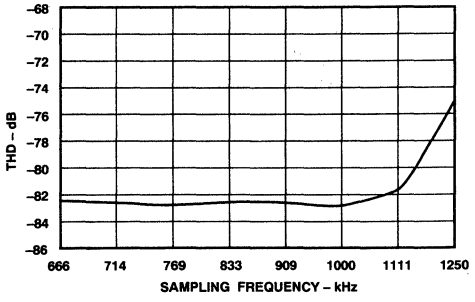

Figure 5. THD vs. Sampling Rate, f_{IN} = 100 kHz

The AD1671's SFDR performance is ideal for use in communication systems such as high speed modems and digital radios. The SFDR is better than 84 dB with sample rates up to 1.11 MHz and increases as the input signal amplitude is attenuated by approximately 3 dB. Note also the SFDR is typically better than 80 dB with input signals attenuated by up to −7 dB.

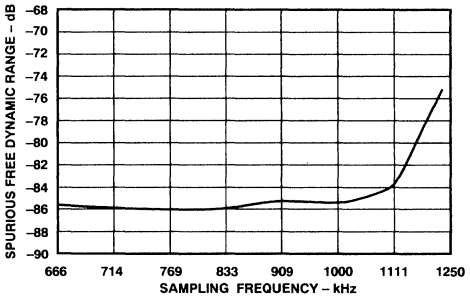

Figure 6. Spurious Free Dynamic Range vs. Sampling Rate, f_{IN} = 100 kHz

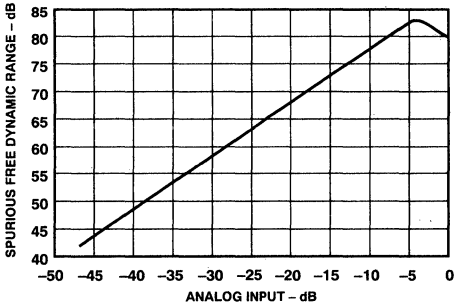

Figure 7. Spurious Free Dynamic Range vs. Input Amplitude, f_{IN} = 250 kHz

APPLYING THE AD1671

GROUNDING AND DECOUPLING RULES

Proper grounding and decoupling should be a primary design objective in any high speed, high resolution system. The AD1671 separates analog and digital grounds to optimize the management of analog and digital ground currents in a system. The AD1671 is designed to minimize the current flowing from REF COM (Pin 20) by directing the majority of the current from V_{CC} (+5 V–Pin 28) to V_{EE} (−5 V–Pin 1). Minimizing analog ground currents hence reduces the potential for large ground voltage drops. This can be especially true in systems that do not utilize ground planes or wide ground runs. REF COM is also configured to be code independent, therefore reducing input dependent analog ground voltage drops and errors. Code dependent ground current is diverted to ACOM (Pin 27). Also critical in any high speed digital design is the use of proper digital grounding techniques to avoid potential CMOS "ground bounce." Figure 3 is provided to assist in the proper layout, grounding and decoupling techniques.

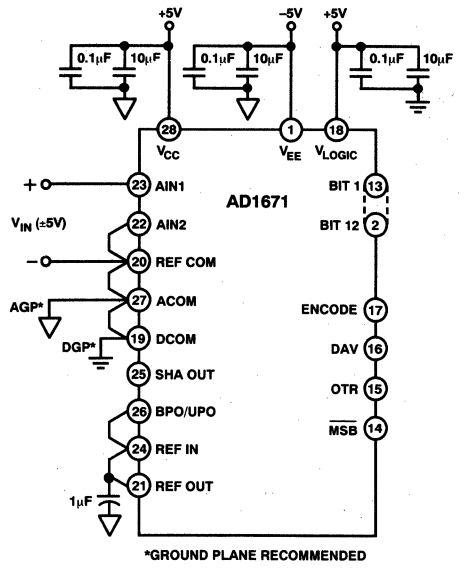

Figure 8. AD1671 Grounding and Decoupling

Table I is a list of grounding and decoupling rules that should be reviewed before laying out a printed circuit board.

Table I. Grounding and Decoupling Guidelines

Power Supply Decoupling	**Comment**
Capacitor Values	0.1 μF (Ceramic) and 1 μF (Tantalum) Surface Mount Chip Capacitors Recommended to Reduce Lead Inductance
Capacitor Locations	Directly at Positive and Negative Supply Pins to Common Ground Plane
Reference (REF OUT)	
Capacitor Value	1 μF (Tantalum) to ACOM
Grounding	
Analog Ground	Ground Plane or Wide Ground Return Connected to the Analog Power Supply
Reference Ground (REF COM)	Critical Common Connections Should be Star Connected to REF COM (as Shown in Figure 8)
Digital Ground	Ground Plane or Wide Ground Return Connected to the Digital Power Supply
Analog and Digital Ground	Connected Together Once at the AD1671

UNIPOLAR (0 V TO +5 V) CALIBRATION

The AD1671 is factory trimmed to minimize offset, gain and linearity errors. In some applications the offset and gain errors of the AD1671 need to be externally adjusted to zero. This is accomplished by trimming the voltage at AIN2 (Pin 22). The circuit in Figure 9 is recommended for calibrating offset and gain errors of the AD1671 when configured in the 0 V to +5 V input range. If the offset trim resistor R1 is used, it should be trimmed as follows, although a different offset can be set for a particular system requirement. This circuit will give approximately ±5 mV of offset trim range. Nominally the AD1671 is intended to have a 1/2 LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above it and below it). Thus, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2 LSB (0.61 mV for 5 V range).

The gain trim is done by applying a signal 1 1/2 LSBs below the nominal full scale (4.998 V for a 5 V range). Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111). This circuit will give approximately ±0.5% FS of adjustment range.

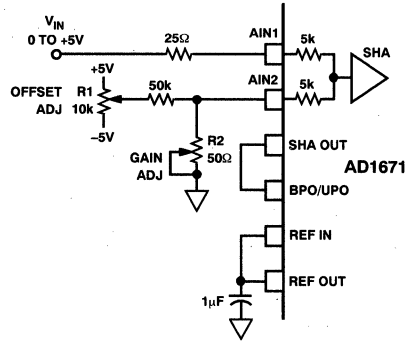

Figure 9. Unipolar (0 V to +5 V) Calibration

BIPOLAR (±5 V) CALIBRATION

The connections for the bipolar ±5 V input range is shown in Figure 10.

Bipolar calibration is similar to unipolar calibration. First, a signal 1/2 LSB above negative full scale (−4.9988 V) is applied and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1 1/2 LSB below positive full scale (+4.9963 V) is applied and R2 is trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

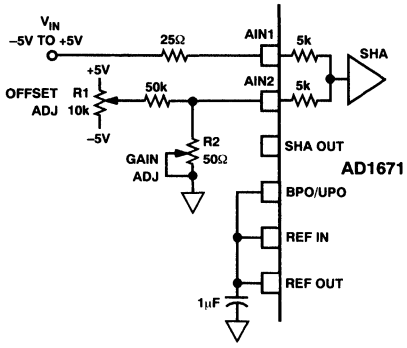

Figure 10. Bipolar (±5 V) Calibration

UNIPOLAR (0 V TO +2.5 V) CALIBRATION

The connections for the 0 V to +2.5 V input range calibration is shown in Figure 11. Figure 11 shows an example of how the offset error can be trimmed in front of the AD1671. The procedure for trimming the offset and gain errors is the same as for the unipolar 5 V range.

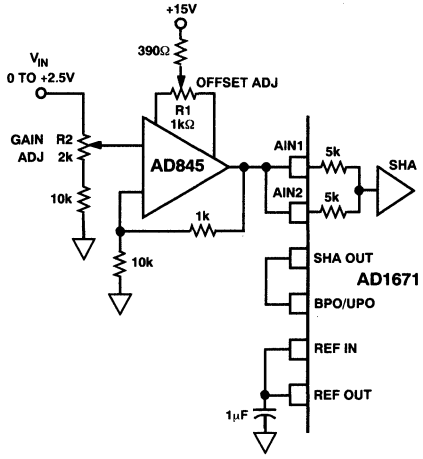

Figure 11. Unipolar (0 V to +2.5 V) Calibration

BIPOLAR (±2.5 V) CALIBRATION

The connections for the bipolar ±2.5 V input range is shown in Figure 12.

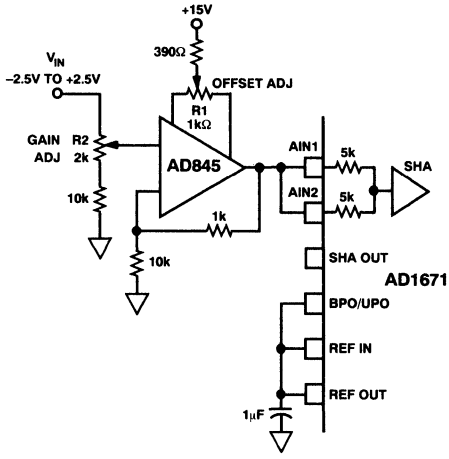

Figure 12. Bipolar (±2.5 V) Calibration

OUTPUT LATCHES

Figure 13 shows the AD1671 connected to the 74HC574 octal D-type edge-triggered latches with 3-state outputs. The latch can drive highly capacitive loads (i.e., bus lines, I/O ports) while maintaining the data signal integrity. The maximum setup and hold times of the 574 type latch must be less than 20 ns (t_{DD} and t_{SS} minimum). To satisfy the requirements of the 574 type latch the recommended logic families are S, AS, ALS, F or BCT. New data from the AD1671 is latched on the rising edge of the DAV (Pin 16) output pulse. Previous data can be latched by inverting the DAV output with a 7404 type inverter.

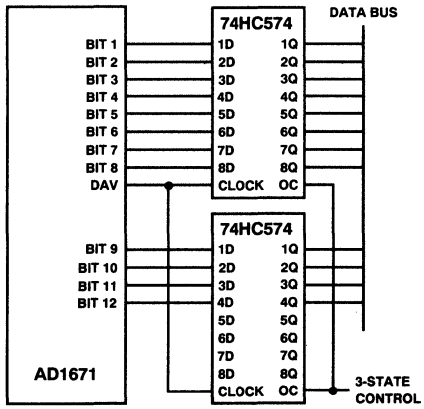

Figure 13. AD1671 to Output Latches

OUT OF RANGE

An out-of-range condition exists when the analog input voltage is beyond the input range (0 V to +2.5 V, 0 V to +5 V, ±2.5 V, ±5 V) of the converter. OTR (Pin 15) is set low when the analog input voltage is within the analog input range. OTR is set HIGH and will remain HIGH when the analog input voltage exceeds the input range by typically 1/2 LSB (OTR transition is tested to ±6 LSBs of accuracy) from the center of the ±full-scale output codes. OTR will remain HIGH until the analog input is within the input range and another conversion is completed. By logical ANDing OTR with the MSB and its complement, overrange high or underrange low conditions can be detected. Table II is a truth table for the over/under range circuit in Figure 14. Systems requiring programmable gain conditioning prior to the AD1671 can immediately detect an out-of-range condition, thus eliminating gain selection iterations.

Table II. Out-of-Range Truth Table

OTR	MSB	Analog Input Is
0	0	In Range
0	1	In Range
1	0	Underrange
1	1	Overrange

OUTPUT DATA FORMAT

The AD1671 provides both MSB and $\overline{MSB}$ outputs, delivering data in positive true straight binary for unipolar input ranges and positive true offset binary or twos complement for bipolar input ranges. Straight binary coding is used for systems that accept positive-only signals. If straight binary coding is used with bipolar input signals, a 0 V input would result in a binary output of 2048. The application software would have to subtract 2048 to determine the true input voltage. Host registers typically perform math on signed integers and assume data is in that format. Twos complement format minimizes software overhead which is especially important in high speed data transfers, such as a DMA operation. The CPU is not bogged down performing data conversion steps, hence the total system throughput is increased.

OPTIONAL EXTERNAL REFERENCE

The AD1671 includes an on-board +2.5 V reference. The reference input pin (REF IN) can be connected to reference output pin (REF OUT) or a standard external +2.5 V reference can be selected to meet specific system requirements. Fast switching input dependent currents are modulated at the reference input. The reference input voltage can be held with the use of a capacitor. To prevent the AD1671's on-board reference from oscillating when not connected to REF IN, REF OUT must be connected to +5 V. It is possible to connect REF OUT to +5 V due to its output circuit implementation which shuts down the reference.

I_{LOGIC} vs. CONVERSION RATE

Figure 15 is the typical logic supply current vs. conversion rate for various capacitor loads on the digital outputs.

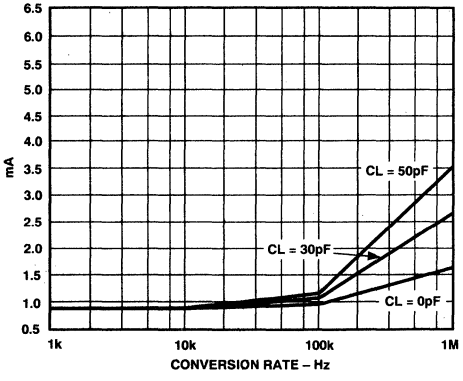

Figure 15. I_{LOGIC} vs. Conversion Rate for Various Capacitive Loads on the Digital Outputs

APPLICATIONS

AD1671 TO ADSP-2100A

Figure 16 demonstrates the AD1671 to ADSP-2100A interface. The 2100A with a clock frequency of 12.5 MHz can execute an instruction in one 80 ns cycle. The AD1671 is configured to perform continuous time sampling. The DAV output of the AD1671 is asserted at the end of each conversion. DAV can be used to latch the conversion result into the two 574 octal D-latches. The falling edge of the sampling clock is used to generate an interrupt (IRQ3) for the processor. Upon interrupt, the ADSP-2100A starts a data memory read by providing an address on the DMA bus. The decoded address generates OE for the latches and the processor reads their output over the DMA bus. The conversion result is read within a single processor cycle.

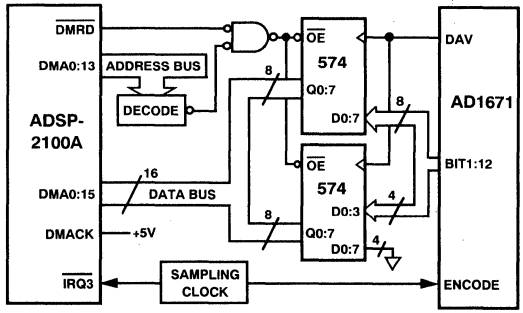

Figure 16. AD1671 to ADSP-2100A Interface

AD1671 TO ADSP-2101/2102

Figure 17 is identical to the 2100A interface except the sampling clock is used to generate an interrupt (IRQ2) for the processor. Upon interrupt the ADSP-2100A starts a data memory read by providing an address on the address (A) bus. The decode address generates OE for the D-latches and the processor reads their output over the Data (D) bus. Reading the conversion result is thus completed within a single processor cycle.

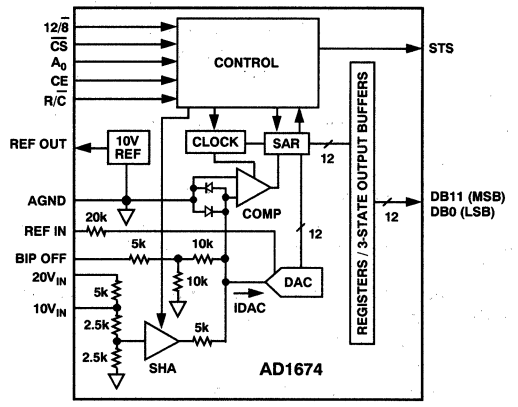
12-Bit 100 kSPS A/D Converter

AD1674*

FEATURES

Complete Monolithic 12-Bit 10 μs Sampling ADC
On-Board Sample-and-Hold Amplifier
Industry Standard Pinout
8- and 16-Bit Microprocessor Interface
AC and DC Specified and Tested
Unipolar and Bipolar Inputs
±5 V, ±10 V, 0–10 V, 0–20 V Input Ranges
Commercial, Industrial and Military Temperature Range Grades
MIL-STD-883 and SMD Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1674 is a complete, multipurpose, 12-bit analog-to-digital converter, consisting of a user-transparent on-board sample-and-hold amplifier (SHA), 10 volt reference, clock and three-state output buffers for microprocessor interface.

The AD1674 is pin compatible with the industry standard AD574A and AD674A, but includes a sampling function while delivering a faster conversion rate. The on-chip SHA has a wide input bandwidth supporting 12-bit accuracy over the full Nyquist bandwidth of the converter.

The AD1674 is fully specified for ac parameters (such as S/(N+D) ratio, THD, and IMD) and dc parameters (offset, full-scale error, etc.). With both ac and dc specifications, the AD1674 is ideal for use in signal processing and traditional dc measurement applications.

The AD1674 design is implemented using Analog Devices' BiMOS II process allowing high performance bipolar analog circuitry to be combined on the same die with digital CMOS logic.

Five different temperature grades are available. The AD1674J and K grades are specified for operation over the 0°C to +70°C temperature range. The A and B grades are specified from −40°C to +85°C; the AD1674T grade is specified from −55°C to +125°C. The J and K grades are available in both 28-lead plastic DIP and SOIC. The A and B grade devices are available in 28-lead hermetically sealed ceramic DIP and 28-lead SOIC. The T grade is available in 28-lead hermetically sealed ceramic DIP.

***Protected by U. S. Patent Nos. 4,962,325; 4,250,445; 4,808,908; RE30586.**

PRODUCT HIGHLIGHTS

Industry Standard Pinout: The AD1674 utilizes the pinout established by the industry standard AD574A and AD674A.

Integrated SHA: The AD1674 has an integrated SHA which supports the full Nyquist bandwidth of the converter. The SHA function is transparent to the user; no wait-states are needed for SHA acquisition.

DC and AC Specified: In addition to traditional dc specifications, the AD1674 is also fully specified for frequency domain ac parameters such as total harmonic distortion, signal-to-noise ratio and input bandwidth. These parameters can be tested and guaranteed as a result of the on-board SHA.

Analog Operation: The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 V and 0 to +20 V unipolar, −5 V to +5 V and −10 V to +10 V bipolar. The AD1674 operates on +5 V and ±12 V or ±15 V power supplies.

Flexible Digital Interface: On-chip multiple-mode three-state output buffers and interface logic allow direct connection to most microprocessors.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

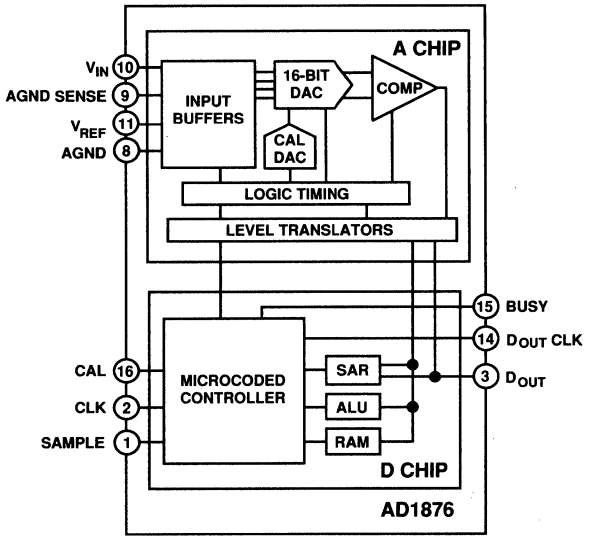
FUNCTIONAL BLOCK DIAGRAM



PRODUCTION DESCRIPTION

The AD1876 is a 16-bit serial output sampling A/D converter which uses a switched capacitor/charge redistribution architecture to achieve a 100 kSPS conversion rate (10 μs total conversion time). Overall performance is optimized by digitally correcting internal nonlinearities through on-chip autocalibration.

The circuitry of the AD1876 is partitioned onto two monolithic chips, a digital control chip fabricated with Analog Devices' DSP CMOS process and an analog ADC chip fabricated with the BiMOS II process. Both chips are contained in a single package.

The serial output interface requires an external clock and sample command signal. The output data rate may be as high as 2.08 MHz, and is controlled by the external clock. The twos complement format of the output data is MSB first and is directly compatible with the NPC SM5805 digital decimation filter used in consumer audio products. The AD1876 is also compatible with a variety of DSP processors.

The AD1876 is packaged in a space saving 16-pin plastic DIP and operates from +5 V and ±12 V supplies; typical power consumption is 235 mW. The digital supply (V_{DD}) is isolated from the linear supplies (V_{EE} and V_{CC}) for reduced digital crosstalk. Separate analog and digital grounds are also provided.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Soldering . . . . . +300°C, 10 sec
Storage Temperature . . . . . −60°C to +100°C

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD SENSITIVITY

The AD1876 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD1876 has been classified as a Category 1 Device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment, and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam discharged to the destination socket before devices are removed. For further information on ESD precaution, refer to Analog Devices' *ESD Prevention Manual.*

TIMING SPECIFICATIONS[1] (T_{min} to T_{max}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%, V_{REF} = 5.00 V)

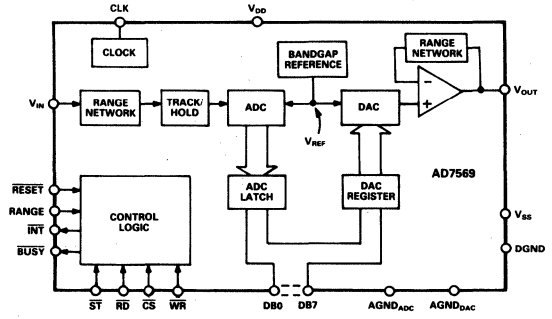
D_{OUT} CLK LOW	t_{DCL}	30	80	200	ns
SAMPLE LOW to 1st CLK Delay	t_{SC}	50			ns
CAL HIGH Time	t_{CALH}	4			t_C
CLK to D_{OUT} CLK	t_{CDH}	150	200	275	ns
SAMPLE LOW	t_{SL}	50			ns

NOTES
[1]See Figure 1 and Figure 2 and the Conversion Control and Autocalibration sections for detailed explanations of the above timing.
[2]Depends upon external clock frequency; includes acquisition time and conversion time. The minimum sampling rate/maximum sampling period is specified to account for droop of the internal sample/hold. Operation at slower rates than specified may degrade performance.

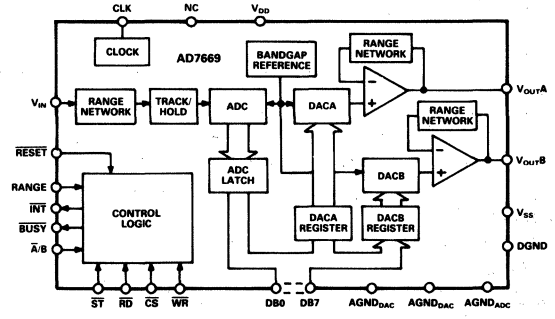
LC²MOS
Complete, 8-Bit Analog I/O System
AD7569/AD7669

FEATURES
2μs ADC with Track/Hold
1μs DAC with Output Amplifier
AD7569, Single DAC Output
AD7669, Dual DAC Output
On-Chip Bandgap Reference
Fast Bus Interface
Single or Dual 5V Supplies

AD7569 FUNCTIONAL BLOCK DIAGRAM



AD7669 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7569/AD7669 is a complete, 8-bit, analog I/O system on a single monolithic chip. The AD7569 contains a high speed successive approximation ADC with 2μs conversion time, a track/hold with 200kHz bandwidth, a DAC and output buffer amplifier with 1μs settling time. A temperature-compensated 1.25V bandgap reference provides a precision reference voltage for the ADC and the DAC. The AD7669 is similar but contains two DACs with output buffer amplifiers.

A choice of analog input/output ranges is available. Using a supply voltage of +5V, input and output ranges of zero to 1.25V and zero to 2.5 volts may be programmed using the RANGE input pin. Using a ±5V supply, bipolar ranges of ±1.25V or ±2.5V may be programmed.

Digital interfacing is via an 8-bit I/O port and standard microprocessor control lines. Bus interface timing is extremely fast, allowing easy connection to all popular 8-bit microprocessors. A separate start convert line controls the track/hold and ADC to give precise control of the sampling period.

The AD7569/AD7669 is fabricated in Linear-Compatible CMOS (LC²MOS), an advanced, mixed technology process combining precision bipolar circuits with low power CMOS logic. The AD7569 is packaged in a 24-pin, 0.3″ wide "skinny" DIP, a 24-terminal SOIC and 28-terminal PLCC and LCCC packages. The AD7669 is available in a 28-pin, 0.6″ plastic DIP, 28-terminal SOIC, and 28-terminal PLCC package.

PRODUCT HIGHLIGHTS

1. Complete Analog I/O on a Single Chip.
   The AD7569/AD7669 provides everything necessary to interface a microprocessor to the analog world. No external components or user trims are required, and the overall accuracy of the system is tightly specified, eliminating the need to calculate error budgets from individual component specifications.
2. Dynamic Specifications for DSP Users.
   In addition to the traditional ADC and DAC specifications the AD7569/AD7669 is specified for AC parameters, including signal-to-noise ratio, distortion and input bandwidth.
3. Fast Microprocessor Interface.
   The AD7569/AD7669 has bus interface timing compatible with all modern microprocessors, with bus access and relinquish times less than 75ns and Write pulse width less than 80ns.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Specifications apply to both DACs in the AD7669. V_{OUT} applies to both V_{OUT}A and V_{OUT}B of the AD7669.

[2]Except where noted, specifications apply for all output ranges including bipolar ranges with dual supply operation.

[3]Temperature ranges are as follows: J, K versions; 0 to +70°C
A, B versions; −40°C to +85°C
S, T versions; −55°C to +125°C

[4]1LSB = 4.88mV for 0 to +1.25V output range, 9.76mV for 0 to +2.5V and ±1.25V ranges and 19.5mV for ±2.5V range.

[5]See Terminology.

[6]Includes internal voltage reference error and is calculated after offset error has been adjusted out. Ideal unipolar full-scale voltage is (FS – 1LSB); ideal bipolar positive full-scale voltage is (FS/2 – 1LSB) and ideal bipolar negative full-scale voltage is −FS/2.

[7]Sample tested at 25°C to ensure compliance.

Specifications subject to change without notice.

ADC SPECIFICATIONS

(V_{DD} = +5V ±5%; V_{SS}[1] = RANGE = $AGND_{DAC}$ = $AGND_{ADC}$ = DGND = 0V; f_{CLK} = 5MHz external unless otherwise stated. All specifications T_{min} to T_{max} unless otherwise stated.) Specifications apply to Mode 1 interface.

NOTES
[1]Except where noted, specifications apply for all ranges including bipolar ranges with dual supply operation.
[2]Temperature ranges are as follows: J, K versions; 0 to +70°C
A, B versions; −40°C to +85°C
S, T versions; −55°C to +125°C
[3]1LSB = 4.88mV for 0 to +1.25V range, 9.76mV for 0 to +2.5V and ±1.25V ranges and 19.5mV for ±2.5V range.
[4]See Terminology.
[5]Includes internal voltage reference error and is calculated after offset error has been adjusted out. Ideal unipolar last code transition occurs at (FS – 3/2LSB); Ideal bipolar last code transition occurs at (FS/2 – 3/2LSB).
[6]Exact frequencies are 101kHz and 384kHz to avoid harmonics coinciding with sampling frequency.
[7]Rising edge of $\overline{BUSY}$ to falling edge of $\overline{ST}$. The time given refers to the acquisition time which gives a 3dB degradation in SNR from the tested figure.
[8]Sample tested at 25°C to ensure compliance.
Specifications subject to change without notice.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The foam should be discharged to the destination socket before devices are removed.

TIMING CHARACTERISTICS[1] (See Figures 8, 10, 12; V_{DD} = 5V ±5%; V_{SS} = 0V or −5V ±5%)

Parameter	Limit at 25°C (All Grades)	Limit at T_{min}, T_{max} (J, K, A, B Grades)	Limit at T_{min}, T_{max} (S, T Grades)	Units	Test Conditions/Comments
DAC Timing					
t_1	80	80	90	ns min	$\overline{WR}$ Pulse Width
t_2	0	0	0	ns min	$\overline{CS}$, A/B to $\overline{WR}$ Setup Time
t_3	0	0	0	ns min	$\overline{CS}$, A/B to $\overline{WR}$ Hold Time
t_4	60	70	80	ns min	Data Valid to $\overline{WR}$ Setup Time
t_5	10	10	10	ns min	Data Valid to $\overline{WR}$ Hold Time
ADC Timing					
t_6	50	50	50	ns min	$\overline{ST}$ Pulse Width
t_7	110	130	150	ns max	$\overline{ST}$ to $\overline{BUSY}$ Delay
t_8	20	30	30	ns max	$\overline{BUSY}$ to $\overline{INT}$ Delay
t_9	0	0	0	ns min	$\overline{BUSY}$ to $\overline{CS}$ Delay
t_{10}	0	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time
t_{11}	60	75	90	ns min	$\overline{RD}$ Pulse Width. Determined by t_{13}.
t_{12}	0	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time
t_{13}[2]	60	75	90	ns max	Data Access Time after $\overline{RD}$; C_L = 20pF
	95	120	135	ns max	Data Access Time after $\overline{RD}$; C_L = 100pF
t_{14}[3]	10	10	10	ns min	Bus Relinquish Time after $\overline{RD}$
	60	75	85	ns max	
t_{15}	65	75	85	ns max	$\overline{RD}$ to $\overline{INT}$ Delay
t_{16}	120	140	160	ns max	$\overline{RD}$ to $\overline{BUSY}$ Delay
t_{17}[2]	60	75	90	ns max	Data Valid Time after $\overline{BUSY}$; C_L = 20pF
	90	115	135	ns max	Data Valid Time after $\overline{BUSY}$; C_L = 100pF

NOTES
[1]Sample tested at +25°C to ensure compliance. All input control signals are specified with $t_R = t_F$ = 5ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]t_{13} and t_{17} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross either 0.8V or 2.4V.
[3]t_{14} is defined as the time required for the data line to change 0.5V when loaded with the circuit of Figure 2.
Specifications subject to change without notice.

PIN FUNCTION DESCRIPTION

(Applies to the AD7569 and AD7669 unless otherwise stated.)

Pin Mnemonic	Description
$AGND_{DAC}$	Analog Ground for the DAC(s). Separate ground return paths are provided for the DAC(s) and ADC to minimize crosstalk.
V_{OUT} ($V_{OUT}A$, $V_{OUT}B$)	Output Voltage. V_{OUT} is the buffered output voltage from the AD7569 DAC. $V_{OUT}A$ and $V_{OUT}B$ are the buffered DAC output voltages from the AD7669. Four different output voltage ranges can be achieved (see Table I).
V_{SS}	Negative Supply Voltage (−5V for dual supply or 0V for single supply). This pin is also used with the RANGE pin to select the different input/output ranges and changes the data format from binary (V_{SS} = 0V) to 2s complement (V_{SS} = −5V) (see Table I).
RANGE	Range Selection Input. This is used with the V_{SS} input to select the different ranges as per Table I. The range selected applies to both the analog input voltage of the ADC and the output voltage from the DAC(s).
$\overline{RESET}$	Reset Input (Active Low). This is an asynchronous system reset which clears the DAC register(s) to all 0s and clears the $\overline{INT}$ line of the ADC (i.e., makes the ADC ready for new conversion). In unipolar operation this input sets the output voltage to 0V; in bipolar operation it sets the output to negative full scale.
DB7	Data Bit 7. Most Significant Bit (MSB).
DB6–DB2	Data Bit 6 to Data Bit 2.
DGND	Digital Ground.
DB1	Data Bit 1.
DB0	Data Bit 0. Least Significant Bit (LSB).
$\overline{WR}$	Write Input (Edge triggered). This is used in conjunction with $\overline{CS}$ to write data into the AD7569 DAC register. It is used in conjunction with $\overline{CS}$ and A/B to write data into the selected DAC register of the AD7669. Data is transferred on the rising edge of $\overline{WR}$.

Pin Mnemonic	Description
$\overline{CS}$	Chip Select Input (Active Low). The device is selected when this input is active.
$\overline{RD}$	READ Input (Active Low). This input must be active to access data from the part. In the Mode 2 interface, $\overline{RD}$ going low starts conversion. It is used in conjunction with the $\overline{CS}$ input (see Digital Interface Section).
$\overline{ST}$	Start Conversion (Edge triggered). This is used when precise sampling is required. The falling edge of $\overline{ST}$ starts conversion and drives $\overline{BUSY}$ low. The $\overline{ST}$ signal is not gated with $\overline{CS}$.
$\overline{BUSY}$	BUSY Status Output (Active Low). When this pin is active the ADC is performing a conversion. The input signal is held prior to the falling edge of $\overline{BUSY}$ (see Digital Interface Section).
$\overline{INT}$	INTERRUPT Output (Active Low). $\overline{INT}$ going low indicates that the conversion is complete. $\overline{INT}$ goes high on the rising edge of $\overline{CS}$ or $\overline{RD}$ and is also set high by a low pulse on $\overline{RESET}$ (see Digital Interface Section).
A/B (AD7669 Only)	DAC Select Input. This input selects which DAC register data is written to under control of $\overline{CS}$ and $\overline{WR}$. With this input low data is written to the DACA register; with this input high data is written to the DACB register.
CLK	A TTL compatible clock signal may be used to determine the ADC conversion time. Internal clock operation is achieved by connecting a resistor and capacitor to ground.
$AGND_{ADC}$	Analog Ground for the ADC.
V_{IN}	Analog Input. Various input ranges can be selected (see Table I).
V_{DD}	Positive Supply Voltage (+5V).

Range	V_{SS}	Input/Output Voltage Range	DB0–DB7 Data Format
0	0V	0 to +1.25V	Binary
1	0V	0 to +2.5V	Binary
0	−5V	±1.25V	2s Complement
1	−5V	±2.5V	2s Complement

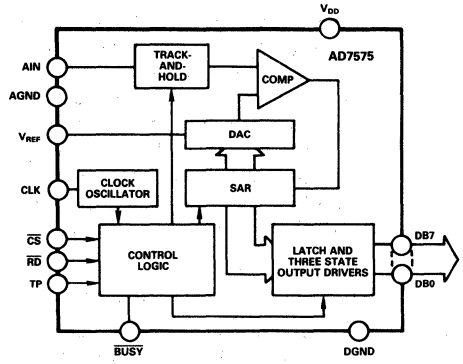
LC²MOS
5µs 8-Bit ADC with Track/Hold
AD7575

FEATURES
- **Fast Conversion Time: 5µs**
- **On-Chip Track/Hold**
- **Low Total Unadjusted Error: 1LSB**
- **Full Power Signal Bandwidth: 50kHz**
- **Single +5V Supply**
- **100ns Data Access Time**
- **Low Power (15mW typ)**
- **Low Cost**
- **Standard 18-Pin DIPs or 20-Terminal Surface Mount Packages**

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7575 is a high-speed 8-bit ADC with a built-in track/hold function. The successive approximation conversion technique is used to achieve a fast conversion time of 5µs, while the built-in track/hold allows full-scale signals up to 50kHz (386mV/µs slew rate) to be digitized. The AD7575 requires only a single +5V supply and a low-cost, 1.23V bandgap reference in order to convert an input signal range of 0 to $2V_{REF}$.

The AD7575 is designed for easy interfacing to all popular 8-bit microprocessors using standard microprocessor control signals ($\overline{CS}$ and $\overline{RD}$) to control starting of the conversion and reading of the data. The interface logic allows the AD7575 to be easily configured as a memory mapped device and the part can be interfaced as SLOW-MEMORY or ROM. All data outputs of the AD7575 are latched and three-state buffered to allow direct connection to a microprocessor data bus or I/O port.

The AD7575 is fabricated in an advanced, all ion-implanted high speed Linear Compatible CMOS (LC²MOS) process and is available in a small, 0.3" wide, 18-pin DIP or in 20-terminal surface mount packages.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time/Low Power
   The fast, 5µs conversion time of the AD7575 makes it suitable for digitizing wideband signals at audio and ultrasonic frequencies, while retaining the advantage of low CMOS power consumption.
2. On-Chip Track/Hold
   The on-chip track/hold function is completely self-contained and requires no external hold capacitor. Signals with slew rates up to 386mV/µs (e.g., 2.46V peak-to-peak 50kHz sine waves) can be digitized with full accuracy.
3. Low Total Unadjusted Error
   The zero, full-scale and linearity errors of the AD7575 are so low that the total unadjusted error at any point on the transfer function is less than 1LSB and offset and gain adjustments are not required.
4. Single Supply Operation
   Operation from a single +5V supply with a low-cost +1.23V bandgap reference allows the AD7575 to be used in 5V microprocessor systems without any additional power supplies.
5. Fast Digital Interface
   Fast interface timing allows the AD7575 to interface easily to the fast versions of most popular microprocessors such as the Z80H, 8085A-2, 6502B, 68B09 and the DSP processor, the TMS32010.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Temperature Ranges are as follows:
J, K Versions; 0 to +70°C
A, B Versions; −25°C to +85°C
S, T Versions; −55°C to +125°C

[2]Offset error is measured with respect to an ideal first code transition which occurs at 1/2LSB.

[3]Sample tested at 25°C to ensure compliance.

[4]Accuracy may degrade at conversion times other than those specified.

[5]Power supply current is measured when AD7575 is inactive i.e. when $\overline{CS}$ = $\overline{RD}$ = $\overline{BUSY}$ = logic HIGH.

Specifications subject to change without notice.

TIMING SPECIFICATIONS[1] (V_{DD} = +5V, V_{REF} = +1.23V, AGND = DGND = 0V)

Parameter	Limit at +25°C (All Versions)	Limit at T_{min}, T_{max} (J, K, A, B Versions)	Limit at T_{min}, T_{max} (S, T Versions)	Units	Conditions/Comments
t_1	0	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time
t_2	100	100	120	ns max	$\overline{RD}$ to $\overline{BUSY}$ Propagation Delay

t_5	0	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time
t_6[2]	80	80	100	ns max	Data Access Time after $\overline{BUSY}$
t_7[3]	10	10	10	ns min	Data Hold Time
	80	80	100	ns max	
t_8	0	0	0	ns min	$\overline{BUSY}$ to $\overline{CS}$ Delay

NOTES
[1]Timing Specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with tr = tf = 20ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]t_3 and t_6 are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[3]t_7 is defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

TERMINOLOGY

LEAST SIGNIFICANT BIT (LSB)
An ADC with 8-bits resolution can resolve 1 part in 2^8 (i.e., 256) of full scale. For the AD7575 with +2.46V full scale one LSB is 9.61mV.

TOTAL UNADJUSTED ERROR
This is a comprehensive specification which includes full scale error, relative accuracy and offset error.

RELATIVE ACCURACY
Relative Accuracy is the deviation of the ADC's actual code transition points from a straight line drawn between the devices measured first LSB transition point and the measured full scale transition point.

SNR
Signal-to-Noise Ratio (SNR) is the ratio of the desired signal to the noise produced in the sampled and digitized analog signal. SNR is dependent on the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical SNR for a sine wave input is given by

$$SNR = (6.02N + 1.76)dB$$

where N is the number of bits in the ADC.

FULL SCALE ERROR (GAIN ERROR)
The gain of a unipolar ADC is defined as the difference between the analog input levels required to produce the first and the last digital output code transitions. Gain error is a measure of the deviation of the actual span from the ideal span of FS – 2LSB's.

ANALOG INPUT RANGE
With V_{REF} = +1.23V the maximum analog input voltage range is 0 to +2.46V. The output data in LSB's is related to the analog input voltage by the integer value of the following expression:

$$\text{Data (LSB's)} = \frac{256\ AIN}{2V_{REF}} + 0.5$$

SLEW RATE
Slew Rate is the maximum allowable rate of change of input signal such that the digital sample values are not in error. Slew Rate limitations may restrict the analog signal bandwidth for full-scale analog signals below the bandwidth allowed from sampling theorem considerations.

ANALOG DEVICES

LC²MOS 16-Bit A/D Converter

AD7701

FEATURES

Monolithic 16-Bit ADC
0.0015% Linearity Error
On-Chip Self-Calibration Circuitry
Programmable Low Pass Filter
0.1 Hz to 10 Hz Corner Frequency
0 to +2.5 V or ±2.5 V Analog Input Range
4 kSPS Output Data Rate
Flexible Serial Interface
Ultralow Power

APPLICATIONS

Industrial Process Control
Weigh Scales
Portable Instrumentation
Remote Data Acquisition

GENERAL DESCRIPTION

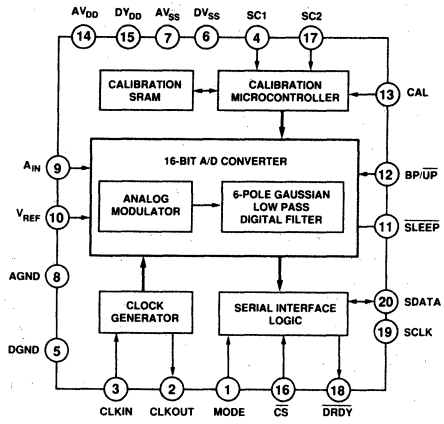
The AD7701 is a 16-bit ADC which uses a sigma delta conversion technique. The analog input is continuously sampled by an analog modulator whose mean output duty cycle is proportional to the input signal. The modulator output is processed by an on-chip digital filter with a six-pole Gaussian response, which updates the output data register with 16-bit binary words at word rates up to 4 kHz. The sampling rate, filter corner frequency and output word rate are set by a master clock input that may be supplied externally, or by a crystal-controlled on-chip clock oscillator.

The inherent linearity of the ADC is excellent, and end-point accuracy is ensured by self-calibration of zero and full-scale which may be initiated at any time. The self-calibration scheme can also be extended to null system offset and gain errors in the input channel.

The output data is accessed through a flexible serial port, which has an asynchronous mode compatible with UARTs and two synchronous modes suitable for interfacing to shift registers or the serial ports of industry-standard microcontrollers.

CMOS construction insures low power dissipation, and a power down mode reduces the idle power consumption to only 10 μW.

FUNCTIONAL BLOCK DIAGRAM



PRODUCT HIGHLIGHTS

1. The AD7701 offers 16-bit resolution coupled with outstanding 0.0015% accuracy.
2. No missing codes ensures true, usable, 16-bit dynamic range, removing the need for programmable gain and level-setting circuitry.
3. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero and gain error. External circuits can also be included in the calibration loop to remove system offsets and gain errors.
4. A flexible synchronous/asynchronous interface allows the AD7701 to interface directly to UARTs or to the serial ports of industry-standard microcontrollers.
5. Low operating power consumption and an ultralow power standby mode make the AD7701 ideal for loop-powered remote sensing applications, or battery-powered portable instruments.

NOTES
[1]The A_{IN} pin presents a very high impedance dynamic load which varies with clock frequency.
[2]Temperature ranges are as follows: A, B Versions; −40°C to +85°C; S, T Versions; −55°C to +125°C.
[3]Apply after calibration at the temperature of interest. Full-scale error applies for both unipolar and bipolar input ranges.
[4]Total drift over the specified temperature range since calibration at power-up at +25°C. This is guaranteed by design and/or characterization. Recalibration at any temperature will remove these errors.
[5]In unipolar mode the offset can have a negative value ($-V_{REF}$) such that the unipolar mode can mimic bipolar mode operation.
[6]The specifications for input overrange and for input span apply additional constraints on the offset calibration range.
[7]For unipolar mode, input span is the difference between full-scale and zero scale. Fir bipolar mode, input span is the difference between positive and negative full-scale points. When using less than the maximum input span, the span range may be placed anywhere within the range of $\pm(V_{REF} + 0.1)$.
[8]All digital outputs unloaded. All digital inputs at 5 V CMOS levels.
[9]Applies in 0.1 Hz to 10 Hz bandwidth. PSRR at 60 Hz will exceed 120 dB due to the digital filter.
[10]CLKIN is stopped. All digital inputs are grounded.

Specifications subject to change without notice.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Transient currents of up to 100 mA will not cause SCR latch-up.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	MODE	Selects the Serial Interface Mode. If MODE is tied to −5 V, the AD7701 will operate in the asynchronous communications (AC) mode. The SCLK pin is configured as an input, and data is transmitted in two bytes, each with one start bit and two stop bits. If MODE is tied to DGND, the synchronous external clocking (SEC) mode is selected. SCLK is configured as an input, and the output appears without formatting, the MSB coming first. If MODE is tied to +5 V, the AD7701 operates in the synchronous self-clocking (SSC) mode. SCLK is configured as an output, with a clock frequency of $f_{CLKIN}/4$ and 25% duty-cycle.
2	CLKOUT	Clock Output to generate an Internal Master Clock by connecting a crystal between CLKOUT and CLKIN. If an external clock is used, CLKOUT is not connected.
3	CLKIN	Clock Input for External Clock.
4, 17	SC1, SC2	System Calibration Pins. The state of these pins, when CAL is taken high, determines the type of calibration performed.
5	DGND	Digital Ground. Ground reference for all digital signals.
6	DV_{SS}	Digital Negative Supply, −5 V nominal.
7	AV_{SS}	Analog Negative Supply, −5 V nominal.
8	AGND	Analog Ground. Ground reference for all analog signals.
9	A_{IN}	Analog Input.
10	V_{REF}	Voltage Reference Input, +2.5 V nominal. This determines the value of positive full-scale in the unipolar mode and of both positive and negative full-scale in the bipolar mode.
11	$\overline{SLEEP}$	Sleep mode pin. When this pin is taken low, the AD7701 goes into a low-power mode with typically 10 μW power consumption.
12	BP/$\overline{UP}$	Bipolar/Unipolar Mode Pin. When this pin is low, the AD7701 is configured for a unipolar input range going from AGND to V_{REF}. When Pin 12 is high, the AD7701 is configured for a bipolar input range, $\pm V_{REF}$.
13	CAL	Calibration Mode Pin. When CAL is taken high for more than 4 cycles, the AD7701 is reset and performs a calibration cycle when CAL is brought low again. The CAL pin can also be used as a strobe to synchronize the operation of several AD7701s.
14	AV_{DD}	Analog Positive Supply, +5 V nominal.
15	DV_{DD}	Digital Positive Supply, +5 V nominal.
16	$\overline{CS}$	Chip Select Input. When $\overline{CS}$ is brought low, the AD7701 will begin to transmit serial data in a format determined by the state of the MODE pin.
18	$\overline{DRDY}$	Data Ready output. $\overline{DRDY}$ is low when valid data is available in the output register. It goes high after transmission of a word is completed. It also goes high for four clock cycles when a new data word is being loaded into the output register, to indicate that valid data is not available, irrespective of whether data transmission is complete or not.
19	SCLK	Serial Clock Input/Output. The SCLK pin in configured as an input or output, dependent on the type of serial data transmission that has been selected by the MODE pin. When configured as an output in the synchronous self-clocking mode, it has a frequency of $f_{CLKIN}/4$ and a duty cycle of 25%.
20	SDATA	Serial Data Output. The AD7701's output data is available at this pin as a 16-bit serial word. The transmission format is determined by the state of the MODE pin.

TIMING CHARACTERISTICS[1, 2]

(AV_{DD} = DV_{DD} = +5 V ± 10%; AV_{SS} = DV_{SS} = −5 V ± 10%; AGND = DGND = 0 V; f_{CLKIN} = 4.096 MHz; Input Levels: Logic 0 = 0 V, Logic 1 = DV_{DD})

Parameter	Limit at T_{min}, T_{max} (A, B Versions)	Limit at T_{min}, T_{max} (S, T Versions)	Units	Conditions/Comments
f_{CLKIN}[3, 4]	40	40	kHz min	Master Clock Frequency: Internal Gate Oscillator
	5	5	MHz max	Typically 4.096 MHz
	40	40	kHz min	Master Clock Frequency: Externally Supplied
	5	5	MHz max	
t_r[5]	50	50	ns max	Digital Output Rise Time. Typically 20 ns
t_f[5]	50	50	ns max	Digital Output Fall Time. Typically 20 ns
t_1	0	0	ns min	SC1, SC2 to CAL High Setup Time
t_2	50	50	ns min	SC1, SC2 Hold Time After CAL Goes High
t_3[6]	1000	1000	ns min	$\overline{SLEEP}$ High to CLKIN High Setup Time
SSC Mode				
t_4[7]	$3/f_{CLKIN}$	$3/f_{CLKIN}$	ns min	Data Access Time ($\overline{CS}$ Low to Data Valid)
t_5	100	100	ns max	SCLK Falling Edge to Data Valid Delay (25 ns typ)
t_6	250	250	ns min	MSB Data Setup Time. Typically 380 ns
t_7	300	300	ns max	SCLK High Pulse Width. Typically 240 ns
t_8	790	790	ns max	SCLK Low Pulse Width. Typically 730 ns
t_9[8]	$1/f_{CLKIN}$ +200	$1/f_{CLKIN}$ +200	ns max	SCLK Rising Edge to Hi-Z Delay ($1/f_{CLKIN}$ +100 ns typ)
t_{10}[8, 9]	$(4/f_{CLKIN})$ +200	$(4/f_{CLKIN})$ +200	ns max	$\overline{CS}$ High to Hi-Z Delay
SEC Mode				
f_{SCLK}	5	5	MHz	Serial Clock Input Frequency
t_{11}	50	50	ns min	SCLK Input High Pulse Width
t_{12}	180	180	ns min	SCLK Low Pulse Width
t_{13}[7, 10]	160	160	ns max	Data Access Time ($\overline{CS}$ Low to Data Valid). Typically 80 ns
t_{14}[11]	150	150	ns min	SCLK Falling Edge to Data Valid Delay. Typically 75 ns
t_{15}[8]	250	250	ns min	$\overline{CS}$ High to Hi-Z Delay
t_{16}[8]	200	200	ns min	SCLK Falling Edge to Hi-Z Delay. Typically 100 ns
AC Mode				
t_{17}	40	40	ns max	$\overline{CS}$ Setup Time. Typically 20 ns
t_{18}	180	180	ns max	Data Delay Time. Typically 90 ns
t_{19}	200	200	ns max	SCLK Falling Edge to Hi-Z Delay. Typically 100 ns

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]See Figures 1 to 5.

[3]CLKIN Duty Cycle range is 20% to 80%. CLKIN must be supplied whenever the AD7701 is not in SLEEP mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7701 is production tested with f_{CLKIN} at 4.096 MHz. It is guaranteed by characterization to operate at 200 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]In order to synchronize several AD7701s together using the $\overline{SLEEP}$ pin, this specification is met.

[7]t_4 and t_{13} are measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[8]t_8, t_{10}, t_{15} and t_{16} are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time quoted in the Timing Characteristics is the true bus relinquish time of the part and as such as independent of external bus loading capacitance.

[9]If $\overline{CS}$ is returned high before all 16 bits are output, the SDATA and SCLK outputs will complete the current data bit and then go to high impedance.

[10]If $\overline{CS}$ is activated asynchronously to $\overline{DRDY}$, $\overline{CS}$ will not be recognized if it occurs when $\overline{DRDY}$ is high for four clock cycles. The propagation delay time may be as great as 4 CLKIN cycles plus 160 ns. To guarantee proper clocking of SDATA when using asynchronous $\overline{CS}$, the SCLK input should not be taken high sooner then 4 CLKIN cycles plus 160 ns after $\overline{CS}$ goes low.

[11]SDATA is clocked out on the falling edge of the SCLK input.

TERMINOLOGY

LINEARITY ERROR
This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are Zero-Scale (not to be confused with Bipolar Zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and Full-Scale, a point 1.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

DIFFERENTIAL LINEARITY ERROR
This is the difference between any code's actual width and the ideal (1 LSB) width. Differential Linearity Error is expressed in LSBs. A differential linearity specification of ±1 LSB or less guarantees monotonicity.

POSITIVE FULL-SCALE ERROR
Positive Full-Scale Error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal (V_{REF} −3/2 LSBs). It applies to both positive and negative analog input ranges and it is expressed in microvolts.

UNIPOLAR OFFSET ERROR
Unipolar Offset Error is the deviation of the first code transition from the ideal (AGND + 0.5 LSB) when operating in the unipolar mode. It is expressed in microvolts.

BIPOLAR ZERO ERROR
This is the deviation of the mid-scale transition (0111 . . . 111 to 1000 . . . 000) from the ideal (AGND − 0.5 LSB) when operating in the bipolar mode. It is expressed in microvolts.

BIPOLAR NEGATIVE FULL-SCALE ERROR
This is the deviation of the first code transition from the ideal ($-V_{REF}$ + 0.5 LSB), when operating in the bipolar mode. It is expressed in microvolts.

POSITIVE FULL-SCALE OVERRANGE
Positive Full-Scale Overrange is the amount of overhead available to handle input voltages greater than $+V_{REF}$ (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter. It is expressed in millivolts.

NEGATIVE FULL-SCALE OVERRANGE
This is the amount of overhead available to handle voltages below $-V_{REF}$ without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode. The overhead is expressed in millivolts.

LC²MOS 20-Bit A/D Converter

AD7703

FEATURES
Monolithic 20-Bit ADC
0.0003% Linearity Error
20-Bit No Missed Codes
On-Chip Self-Calibration Circuitry
Programmable Low-Pass Filter
0.1 Hz to 10 Hz Corner Frequency
0 to +2.5 V or ±2.5 V Analog Input Range
4 kSPS Output Data Rate
Flexible Serial Interface
Ultralow Power

APPLICATIONS
Industrial Process Control
Weigh Scales
Portable Instrumentation
Remote Data Acquisition

GENERAL DESCRIPTION

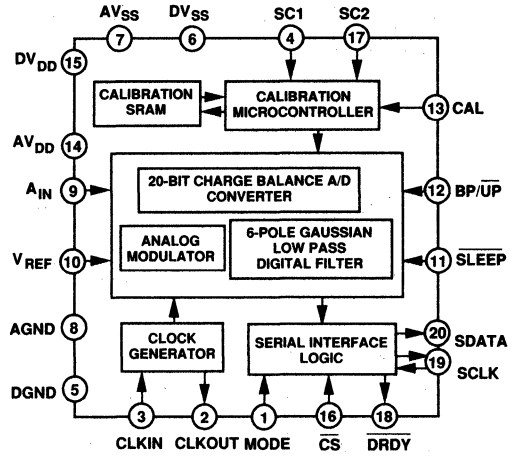
The AD7703 is a 20-bit ADC which uses a sigma delta conversion technique. The analog input is continuously sampled by an analog modulator whose mean output duty cycle is proportional to the input signal. The modulator output is processed by an on-chip digital filter with a six-pole Gaussian response, which updates the output data register with 20-bit binary words at word rates up to 4 kHz. The sampling rate, filter corner frequency and output word rate are set by a master clock input that may be supplied externally, or by an on-chip gate oscillator.

The inherent linearity of the ADC is excellent, and endpoint accuracy is ensured by self-calibration of zero and full scale which may be initiated at any time. The self-calibration scheme can also be extended to null system offset and gain errors in the input channel.

The output data is accessed through a serial port, which has two synchronous modes suitable for interfacing to shift registers or the serial ports of industry standard microcontrollers.

CMOS construction ensures low power dissipation, and a power down mode reduces the idle power consumption to only 10 μW.

FUNCTIONAL BLOCK DIAGRAM



PRODUCT HIGHLIGHTS

1. The AD7703 offers 20-bit resolution coupled with outstanding 0.0003% accuracy.
2. No missing codes ensures true, usable, 20-bit dynamic range, removing the need for programmable gain and level-setting circuitry.
3. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero and gain error. External circuits can also be included in the calibration loop to remove system offsets and gain errors.
4. A flexible synchronization allows the AD7703 to interface directly to the serial ports of industry standard microcontrollers and DSP processors.
5. Low operating power consumption and an ultralow power standby mode make the AD7703 ideal for loop powered remote sensing applications, or battery-powered portable instruments.

A, B, C	20	20	20	μW max	Typically 10 μW
S	40	40	40	μW max	

NOTES
[1]The A_{IN} pin presents a very high impedance dynamic load which varies with clock frequency. A ceramic 1 nF capacitor from the A_{IN} to AGND is necessary. Source resistance should be 750 Ω or less.
[2]Temperature Ranges are as follows: A, B, C Versions: −40°C to +85°C; S Version: −55°C to +125°C.
[3]Applies after calibration at the temperature of interest. Full-Scale Error applies for both unipolar and bipolar input ranges.
[4]Total drift over the specified temperature range after calibration at power-up at +25°C. This is guaranteed by design and/or characterization. Recalibration at any temperature will remove these errors.
[5]In unipolar mode the offset can have a negative value ($-V_{REF}$) such that the unipolar mode can mimic bipolar mode operation.
[6]The specifications for input overrange and for input span apply additional constraints on the offset calibration range.
[7]For unipolar mode, input span is the difference between full scale and zero scale. For bipolar mode, input span is the difference between positive and negative full-scale points. When using less than the maximum input span, the span range may be placed anywhere within the range of $\pm(V_{REF} + 0.1)$.
[8]All digital outputs unloaded. All digital inputs at 5 V CMOS levels.
[9]Applies in 0.1 Hz to 10 Hz bandwidth. PSRR at 60 Hz will exceed 120 dB due to the digital filter.
[10]CLKIN is stopped. All digital inputs are grounded.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

(T_A = +25°C unless otherwise noted)

DV_{DD} to AGND . . . . . −0.3 V to +6 V
DV_{DD} to AV_{DD} . . . . . −0.3 V to +0.3 V

Derates above +75°C by . . . . . 15 mW/°C

NOTES
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[1]Transient currents of up to 100 mA will not cause SCR latch-up.

t_{13}[7, 10]	160	160	ns max	Data Access Time ($\overline{CS}$ Low to Data Valid). Typically 80 ns
t_{14}[11]	150	150	ns min	SCLK Falling Edge to Data Valid Delay. Typically 75 ns
t_{15}[8]	250	250	ns min	$\overline{CS}$ High to Hi-Z Delay
t_{16}[8]	200	200	ns min	SCLK Falling Edge to Hi-Z Delay. Typically 100 ns

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]See Figures 1 to 6.

[3]CLKIN duty cycle range is 20% to 80%. CLKIN must be supplied whenever the AD7703 is not in SLEEP mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7703 is production tested with f_{CLKIN} at 4.096 MHz. It is guaranteed by characterization to operate at 200 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]In order to synchronize several AD7703s together using the $\overline{SLEEP}$ pin, this specification must be met.

[7]t_4 and t_{13} are measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[8]t_9, t_{10}, t_{15} and t_{16} are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time quoted in the Timing Characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

[9]If $\overline{CS}$ is returned high before all 20 bits are output, the SDATA and SCLK outputs will complete the current data bit and then go to high impedance.

[10]If $\overline{CS}$ is activated asynchronously to $\overline{DRDY}$, $\overline{CS}$ will not be recognized if it occurs when $\overline{DRDY}$ is high for four clock cycles. The propagation delay time may be as great as 4 CLKIN cycles plus 160 ns. To guarantee proper clocking of SDATA when using asynchronous $\overline{CS}$, The SCLK input should not be taken high sooner than 4 CLKIN cycles plus 160 ns after $\overline{CS}$ goes low.

[11]SDATA is clocked out on the falling edge of the SCLK input.

TERMINOLOGY

LINEARITY ERROR

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero-scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 1.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

DIFFERENTIAL LINEARITY ERROR

This is the difference between any code's actual width and the ideal (1 LSB) width. Differential linearity error is expressed in LSBs. A differential linearity specification of ±1 LSB or less guarantees monotonicity.

POSITIVE FULL-SCALE ERROR

Positive full-scale error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal (V_{REF} − 3/2 LSBs). It applies to both positive and negative analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar offset error is the deviation of the first code transition from the ideal (AGND + 0.5 LSB) when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal (AGND − 0.5 LSB) when operating in the bipolar mode.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal ($-V_{REF}$ + 0.5 LSB), when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive full-scale overrange is the amount of overhead available to handle input voltages greater than $+V_{REF}$ (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages below $-V_{REF}$ without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode.

OFFSET CALIBRATION RANGE

In the system calibration modes (SC2 Low) the AD7703 calibrates its offset with respect to the A_{IN} pin. The offset calibration range specification defines the range of voltages that the AD7701 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7703 can accept in the system calibration mode and still calibrate full scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7703's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full scale that the AD7703 can accept and still calibrate gain accurately.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	MODE	Selects the Serial Interface Mode. If MODE is tied to DGND, the Synchronous External Clocking (SEC) mode is selected. SCLK is configured as an input, and the output appears without formatting, the MSB coming first. If MODE is tied to +5 V, the AD7703 operates in the Synchronous Self-Clocking (SSC) mode. SCLK is configured as an output, with a clock frequency of $f_{CLKIN}/4$ and 25% duty cycle.
2	CLKOUT	Clock Output to generate an Internal Master Clock by connecting a crystal between CLKOUT and CLKIN. If an external clock is used, CLKOUT is left open circuit.
3	CLKIN	Clock Input for External Clock.
4, 17	SC1, SC2	System Calibration Pins. The state of these pins, when CAL is taken high, determines the type of calibration performed.
5	DGND	Digital Ground. Ground reference for all digital signals.
6	DV_{SS}	Digital Negative Supply, −5 V nominal.
7	AV_{SS}	Analog Negative Supply, −5 V nominal.
8	AGND	Analog Ground. Ground reference for all analog signals.
9	A_{IN}	Analog Input.
10	V_{REF}	Voltage Reference Input, +2.5 V nominal. This determines the value of positive full scale in the unipolar mode and of both positive and negative full-scale in the Bipolar Mode.
11	$\overline{SLEEP}$	Sleep mode pin. When this pin is taken Low, the AD7703 goes into a low-power mode with typically 10 μW power consumption.
12	BP/$\overline{UP}$	Bipolar/Unipolar mode pin. When this pin is low the AD7703 is configured for a unipolar input range of AGND to V_{REF}. When Pin 12 is High, the AD7703 is configured for a bipolar input range, $\pm V_{REF}$.
13	CAL	Calibration mode pin. When CAL is taken High for more than 4 master clock cycles, the AD7703 is reset and performs a calibration cycle when CAL is brought Low again. The CAL pin can also be used as a strobe to synchronize the operation of several AD7703s.
14	AV_{DD}	Analog Positive Supply, +5 V nominal.
15	DV_{DD}	Digital Positive Supply, +5 V nominal.
16	$\overline{CS}$	Chip Select Input. When $\overline{CS}$ is brought low, the AD7703 will begin to transmit serial data in a format determined by the state of the MODE pin.
18	$\overline{DRDY}$	Data Ready Output. $\overline{DRDY}$ is low when valid data is available in the output register. It goes High after transmission of a word is completed. It also goes High for four clock cycles when a new data word is being loaded into the output register, to indicate that valid data is not available, irrespective of whether data transmission is complete or not.
19	SCLK	Serial Clock Input/Output. The SCLK pin in configured as an input or output, dependent on the type of serial data transmission that has been selected by the MODE pin. When configured as an output in the Synchronous Self-Clocking mode, it has a frequency of $f_{CLKIN}/4$ and a duty cycle of 25%.
20	SDATA	Serial Data Output. The AD7703's output data is available at this pin as a 20-bit serial word.

ANALOG DEVICES

LC²MOS Signal Conditioning ADCs

AD7710/AD7712*

FEATURES

Charge Balancing ADC
- **24 Bits No Missing Codes**
- **±0.0015% Nonlinearity**

Two-Channel Programmable Gain Front End
- **Gains from 1 to 128**
- **Differential Input for Low Level Channels**
- **High-Level Input on AD7712**

Low-Pass Filter with Programmable Filter Cutoffs
Ability to Read/Write Calibration Coefficients
Bidirectional Microcontroller Serial Interface
Internal/External Reference Option
Single or Dual Supply Operation
Low Power (25 mW typ) with Power-Down Mode

APPLICATIONS

Weigh Scales
Thermocouples
Process Control
Smart Transmitters
Portable Industrial Instruments

GENERAL DESCRIPTION

The AD7710/AD7712 is a complete analog front end for low frequency measurement applications. The device has two analog input channels and accepts either low level signals directly from a transducer or high level ($\pm 4 \times V_{REF}$ for AD7712 AIN2) signals and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 24 bits of no missing codes performance. The input signals are applied to a proprietary programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

Normally, one of the channels will be used as the main channel with the second channel used as an auxiliary input to periodically measure a second voltage. The part can be operated from a single supply (by tying the V_{SS} pin to AGND) provided that the input signals on the low level analog inputs are more positive than −30 mV. By taking the V_{SS} pin negative, the part can convert signals down to $-V_{REF}$ on the low level inputs. The low-level inputs, as well as the reference input, features differential input capability.

The AD7710/AD7712 is ideal for use in smart, microcontroller-based systems. Input channel selection, gain settings and signal polarity can be configured in software using the bidirectional serial port. The AD7710/AD7712 also contains self-calibration, system calibration and background calibration options and also allows the user to read and to write the on-chip calibration registers.

*Protected by U.S. Patent No. 5,134,401.

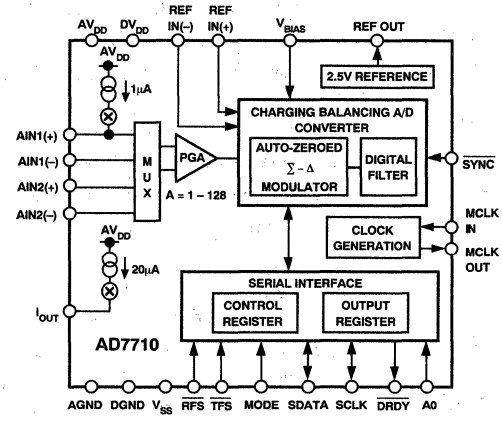
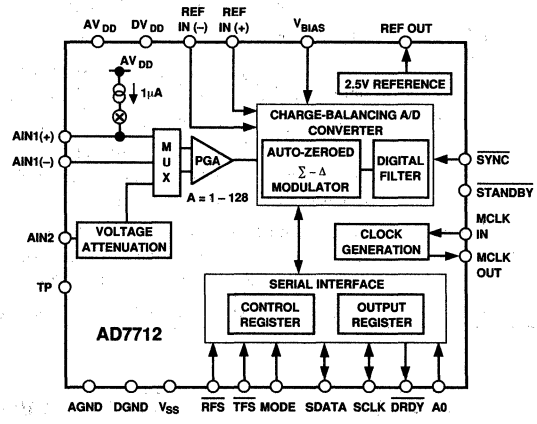
AD7710 FUNCTIONAL BLOCK DIAGRAM



AD7712 FUNCTIONAL BLOCK DIAGRAM



CMOS construction ensures low power dissipation and a power-down mode reduces the standby power consumption to only 100 μW typical (AD7712) and 7 μW typical (AD7710). The part is available in a 24-pin, 0.3 inch wide, plastic and hermetic dual-in-line package (DIP) as well as a 24-lead small outline (SOIC) package.

AD7712–SPECIFICATIONS

(AV_{DD} = +5 V ± 5%; DV_{DD} = +5 V ± 5%; V_{SS} = 0 V or −5 V ± 5%; REF IN(+) = +2.5 V; REF IN(−) = AGND; MCLK IN = 10 MHz unless otherwise stated. All specifications T_{MIN} to T_{MAX}, unless otherwise noted.)

Parameter	A, S Versions[1]	Units	Conditions/Comments
STATIC PERFORMANCE			
No Missing Codes	24	Bits min	Guaranteed by Design. For Filter Notches ≤ 60 Hz

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version, −55°C to +125°C.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part, as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors.

[6]These numbers are guaranteed by design and/or characterization.

[7]This common-mode voltage range is allowed provided that the absolute value of the input voltage on AIN1(+) and AIN1(−) does not exceed AV_{DD} + 30 mV and V_{SS} − 30 mV.

[8]The AIN1 analog input presents a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance depends on the selected gain (see Tables IV and V).

[9]The analog input voltage range on the AIN1(+) input is given here with respect to the voltage on the AIN1(−) input. The input voltage range on the AIN2 input is with respect to AGND. The absolute voltage on the AIN1 input should not go more positive than AV_{DD} + 30 mV or more negative than V_{SS} − 30 mV.

[10]V_{REF} = REF IN(+) − REF IN(−).

Input Span	$3.2 \times V_{REF}/GAIN$	V min	GAIN Is the Selected PGA Gain (Between 1 and 128)
	$(8.4 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)

[11]This error can be removed using the system calibration capabilities of the AD7712. This error is not removed by the AD7712's self-calibration feature. The offset drift on the AIN2 input is 4 times the value given in the STATIC PERFORMANCE section.

[12]The reference voltage range may be restricted by the input voltage range requirement on the V_{BIAS} input.

[13]The AD7712 is tested with the following V_{BIAS} voltages. With AV_{DD} = +5 V and V_{SS} = 0 V, V_{BIAS} = +2.5 V; with AV_{DD} = +10 V and V_{SS} = 0 V, V_{BIAS} = +5 V and with AV_{DD} = +5 V and V_{SS} = −5 V, V_{BIAS} = 0 V.

[14]Sample tested at +25°C to ensure compliance.

[15]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[16]These calibration and span limits apply provided the absolute voltage on the AIN1 analog input does not exceed AV_{DD} + 30 mV or does not go more negative than V_{SS} − 30 mV.

[17]The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

Specifications subject to change without notice.

Parameter	A, S Versions[1]	Units	Conditions/Comments
POWER REQUIREMENTS			
Power Supply Voltages			
AV_{DD} Voltage[18]	+5 to +10	V nom	±5% for Specified Performance
DV_{DD} Voltage[19]	+5	V nom	±5% for Specified Performance
AV_{DD} − V_{SS} Voltage	+10.5	V max	For Specified Performance
Power Supply Currents			
AV_{DD} Current	4	mA max	
DV_{DD} Current	4.5	mA max	
V_{SS} Current	1.5	mA max	V_{SS} = −5 V
Power Supply Rejection[20]			Rejection w.r.t. AGND. Assumes V_{BIAS} Is Fixed
Positive Supply (AV_{DD})	See Note 21	dB typ	
Negative Supply (V_{SS})	90	dB typ	
Power Dissipation			
Normal Mode	45	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V; Typically 25 mW
Normal Mode	52.5	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = −5 V; Typically 30 mW
Standby (Power-Down) Mode[22]	200	μW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V or −5 V; Typically 100 μW

[18]The AD7712 is specified with a 10 MHz clock for AV_{DD} voltages of +5 V ± 5%. It is specified with an 8 MHz clock for AV_{DD} voltages greater than 5.25 V and less than 10.5 V. Operating with AV_{DD} voltages in the range 5.25 V to 10.5 V is only guaranteed over the 0°C to +70°C temperature range.
[19]The ±5% tolerance on the DV_{DD} input is allowed provided DV_{DD} does not exceed AV_{DD} by more than 0.3 V.
[20]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 10 Hz, 25 Hz or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 10 Hz, 30 Hz or 60 Hz.
[21]PSRR depends on gain: gain of 1 = 70 dB typ; gain of 2 = 75 dB typ; gain of 4 = 80 dB typ; gains of 8 to 128 = 85 dB typ. These numbers can be improved (to 95 dB typ) by deriving the V_{BIAS} voltage (via Zener diode or reference) from the AV_{DD} supply.
[22]Using the hardware $\overline{\text{STANDBY}}$ pin. Standby power dissipation using the software standby bit (PD) of the Control Register is 5 mW typ.
Specifications subject to change without notice.

Lead Temperature (Soldering, 10 secs) . . . . . +300°C
Power Dissipation (Any Package) to +75°C . . . . . 450 mW

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD7712AN	−40°C to +85°C	N-24
AD7712AR	−40°C to +85°C	R-24
AD7712AQ	−40°C to +85°C	Q-24
AD7712SQ	−55°C to +125°C	Q-24

Sampling Capacitance[7]	20	pF max	
Analog Inputs[8]			
Input Voltage Range[9]			For Normal Operation. Depends on Gain Selected
	0 to $+V_{REF}$[10]	nom	Unipolar Input Range (B/U Bit of Control Register = 1)
	$\pm V_{REF}$	nom	Bipolar Input Range (B/U Bit of Control Register = 0)
Input Sampling Rate, fs	See Table III		
Reference Inputs			
REF IN(+) − REF IN(−) Voltage[11]	+2.5 to +5	V min to V max	For Specified Performance. Part Functions with Lower V_{REF} Voltages
Input Sampling Rate, f_S	$f_{CLK\ IN}$/512		
REFERENCE OUTPUT			
Output Voltage	2.5	V nom	
Initial Tolerance	±4	% max	
Drift	20	ppm/°C typ	
Output Noise	50	µV typ	pk-pk Noise 0.1 Hz to 10 Hz Bandwidth
Line Regulation (AV_{DD})	1	mV/V max	
Load Regulation	1.5	mV/mA max	Maximum Load Current 1mA
External Current	1	mA max	

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version, −55°C to +125°C. See also Note 16.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors.

[6]This common-mode voltage range is allowed provided that the input voltage on AIN(+) and AIN(−) does not exceed AV_{DD} + 30 mV and V_{SS} − 30 mV.

[7]These numbers are guaranteed by design and/or characterization.

[8]The analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance depends on the selected gain (see Tables IV and V).

[9]The analog input voltage range on the AIN1(+) and AIN2(+) inputs is given here with respect to the voltage on the AIN1(−) and AIN2(−) inputs. The absolute voltage on the analog inputs should not go more positive than AV_{DD} + 30 mV or go more negative than V_{SS} − 30 mV.

[10]V_{REF} = REF IN(+) − REF IN(−).

[11]The reference input voltage range may be restricted by the input voltage range requirement on the V_{BIAS} input.

Parameter	A, S Versions[1]	Units	Conditions/Comments
V_{BIAS} INPUT[12]			
Input Voltage Range	$AV_{DD} - 0.85 \times V_{REF}$		See V_{BIAS} Input Section
	or $AV_{DD} - 3$	V max	Whichever Is Smaller; +5 V/−5 V or +10 V/0 V Nominal AV_{DD}/V_{SS}
	or $AV_{DD} - 2.1$	V max	Whichever Is Smaller; +5 V/0 V Nominal AV_{DD}/V_{SS}
	$V_{SS} + 0.85 \times V_{REF}$		See V_{BIAS} Input Section
	or $V_{SS} + 3$	V min	Whichever Is Greater; +5 V/−5 V or +10 V/0 V Nominal AV_{DD}/V_{SS}
	or $V_{SS} + 2.1$	V min	Whichever Is Greater; +5 V/0 V Nominal AV_{DD}/V_{SS}
V_{BIAS} Rejection	65 to 85	dB typ	Increasing with Gain
LOGIC INPUTS			
Input Current	±10	μA max	
All Inputs Except MCLK IN			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	2.0	V min	
MCLK IN Only			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	3.5	V min	
LOGIC OUTPUTS			
V_{OL}, Output Low Voltage	0.4	V max	I_{SINK} = 1.6 mA
V_{OH}, Output High Voltage	$DV_{DD} - 1$	V min	I_{SOURCE} = 100 μA
Floating State Leakage Current	±10	μA max	
Floating State Output Capacitance[13]	9	pF typ	
TRANSDUCER BURN-OUT			
Current	100	nA nom	
Initial Tolerance	±10	% typ	
Drift	0.1	%/°C typ	
COMPENSATION CURRENT			
Output Current	20	μA nom	
Initial Tolerance	±4	μA max	
Drift	35	ppm/°C typ	
Line Regulation (AV_{DD})	20	nA/V max	AV_{DD} = +5 V
Load Regulation	20	nA/V max	
Output Compliance	$AV_{DD} - 2$	V max	
SYSTEM CALIBRATION			
Positive Full-Scale Calibration Limit[14]	$(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Negative Full-Scale Calibration Limit[14]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Offset Calibration Limit[15]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Input Span[15]	$0.8 \times V_{REF}/GAIN$	V min	GAIN Is the Selected PGA Gain (Between 1 and 128)
	$(2.1 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)

NOTES

[12]The AD7710 is tested with the following V_{BIAS} voltages. With AV_{DD} = +5 V and V_{SS} = 0 V, V_{BIAS} = +2.5 V; with AV_{DD} = +10 V and V_{SS} = 0 V, V_{BIAS} = +5 V and with AV_{DD} = +5 V and V_{SS} = −5 V, V_{BIAS} = 0 V.

[13]Sample tested at +25°C to ensure compliance.

[14]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale then the device will output all 0s.

[15]These calibration and span limits apply provided the absolute voltage on the analog inputs does not exceed AV_{DD} + 30 mV or go more negative than V_{SS} − 30 mV. The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

AD7710–SPECIFICATIONS

Parameter	A, S Versions[1]	Units	Conditions/Comments
POWER REQUIREMENTS			
Power Supply Voltages			
AV_{DD} Voltage[16]	+5 to +10	V nom	±5% for Specified Performance
DV_{DD} Voltage[17]	+5	V nom	±5% for Specified Performance
AV_{DD}–V_{SS} Voltage	+10.5	V max	For Specified Performance
Power Supply Currents			
AV_{DD} Current	4	mA max	
DV_{DD} Current	4.5	mA max	
V_{SS} Current	1.5	mA max	V_{SS} = −5 V
Power Supply Rejection[18]			Rejection w.r.t. AGND; Assumes V_{BIAS} Is Fixed
Positive Supply (AV_{DD})	See Note 19	dB typ	
Negative Supply (V_{SS})	90	dB typ	
Power Dissipation			
Normal Mode	45	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V; Typically 25 mW
Normal Mode	52.5	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = −5 V; Typically 30 mW
Standby (Power-Down) Mode	15	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V or −5 V; Typically 7 mW

NOTES

[16]The AD7710 is specified with a 10 MHz clock for AV_{DD} voltages of +5 V ± 5%. It is specified with an 8 MHz clock for AV_{DD} voltages greater than 5.25 V and less than 10.5 V. Operation with AV_{DD} voltages in the range 5.25 V to 10.5 V is only guaranteed over the 0 to +70°C temperature range.

[17]The ±5% tolerance on the DV_{DD} input is allowed provided that DV_{DD} does not exceed AV_{DD} by more than 0.3 V.

[18]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 10 Hz, 25 Hz or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 10 Hz, 30 Hz or 60 Hz.

[19]PSRR depends on gain: Gain of 1: 70 dB typ; Gain of 2: 75 dB typ; Gain of 4: 80 dB typ; Gains of 8 to 128: 85 dB typ. These numbers can be improved (to 95 dB typ) by deriving the V_{BIAS} voltage (via Zener diode or reference) from the AV_{DD} supply.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

(T_A = +25°C, unless otherwise noted)

AV_{DD} to DV_{DD} . . . . . −0.3 V to +12 V

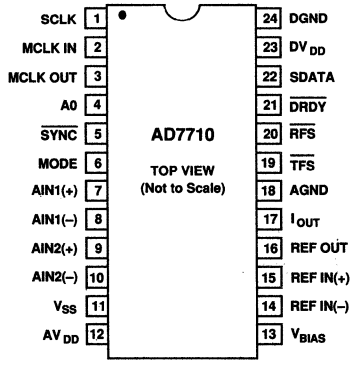
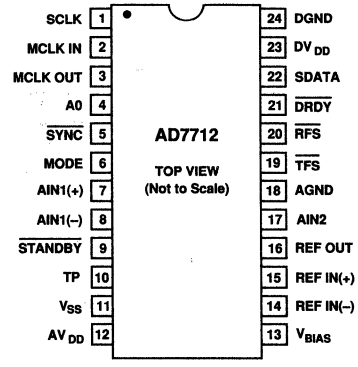
t_{36}	30	ns min	Data Valid to SCLK Hold Time

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are specified with $t_R = t_F = 5$ ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]See Figures 6 to 9.
[3]The AD7710/AD7712 is specified with a 10 MHz clock for AV_{DD} voltages of +5 V ± 5%. It is specified with an 8 MHz clock for AV_{DD} voltages greater than 5.25 V and less than 10.5 V. Operation with AV_{DD} voltages in the range 5.25 V to 10.5 V is only guaranteed over the 0°C to +70°C temperature range.
[4]CLK IN duty cycle range is 45% to 55%. CLK IN must be supplied whenever the AD7710/AD7712 is not in STANDBY mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.
[5]The AD7710/AD7712 is production tested with $f_{CLK\ IN}$ at 10 MHz (8 MHz for AV_{DD} < +5.25 V). It is guaranteed by characterization to operate at 400 kHz.
[6]Specified using 10% and 90% points on waveform of interest.
[7]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross 0.8 V or 2.4 V.
[8]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 100 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and, as such, are independent of external bus loading capacitances.

PIN CONFIGURATION
DIP and SOIC





PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Function
1	SCLK	Serial Clock. Logic Input/Output depending on the status of the MODE pin. When MODE is high, the device is in its self-clocking mode and the SCLK pin provides a serial clock output. This SCLK becomes active when $\overline{RFS}$ or $\overline{TFS}$ goes low and it goes high impedance when either $\overline{RFS}$ or $\overline{TFS}$ returns high or when the device has completed transmission of an output word. When MODE is low, the device is in its external clocking mode and the SCLK pin acts as an input. This input serial clock can be a continuous clock with all data transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7710/AD7712 in smaller batches of data.
2	MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS-compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally 10 MHz.
3	MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT.
4	A0	Address Input. With this input low, reading and writing to the device is to the control register. With this input high, access is to either the data register or the calibration registers.
5	$\overline{SYNC}$	Logic Input which allows for synchronization of the digital filters when using a number of AD7710/AD7712s. It resets the nodes of the digital filter.
6	MODE	Logic Input. When this pin is high, the device is in its self-clocking mode; with this pin low, the device is in its external clocking mode.
7	AIN1(+)	Analog Input Channel 1. Positive input of the programmable gain differential analog input. The AIN1(+) input is connected to an output current source which can be used to check that an external transducer has burnt out or gone open circuit. This output current source can be turned on/off via the control register.
8	AIN1(−)	Analog Input Channel 1. Negative input of the programmable gain differential analog input.
9	AIN2(+)	AD7710 Only. Analog Input Channel 2. Positive input of the programmable gain differential analog input.
9	$\overline{STANDBY}$	AD7712 Only. Logic Input. Taking this pin low shuts down the internal analog and digital circuitry, reducing power consumption to less than 50 μW.
10	AIN2(−)	AD7710 Only. Analog Input Channel 2. Negative input of the programmable gain differential analog input.
10	TP	AD7712 Only. Test Pin. Used when testing the device. Do not connect anything to this pin.
11	V_{SS}	Analog Negative Supply, 0 V to −5 V. Tied to AGND for single supply operation. The input voltage on AIN1 should not go > 30 mV negative w.r.t. V_{SS} for correct operation of the device.
12	AV_{DD}	Analog Positive Supply Voltage, +5 V to +10 V.
13	V_{BIAS}	Input Bias Voltage. This input voltage should be set such that $V_{BIAS} + 0.85 \times V_{REF} < AV_{DD}$ and $V_{BIAS} - 0.85 \times V_{REF} > V_{SS}$ where V_{REF} is REF IN(+) − REF IN(−). Ideally, this should be tied halfway between AV_{DD} and V_{SS}. Thus, with AV_{DD} = +5 V and V_{SS} = 0, it can be tied to REF OUT; with AV_{DD} = +5 V and V_{SS} = −5 V, it can be tied to AGND, while with AV_{DD} = +10 V, it can be tied to +5 V or to REF OUT.
14	REF IN(−)	Reference Input. The REF IN(−) can lie anywhere between AV_{DD} and V_{SS} provided REF IN(+) is greater than REF IN(−).
15	REF IN(+)	Reference Input. The reference input is differential providing that REF IN(+) is greater than REF IN(−). REF IN(+) can lie anywhere between AV_{DD} and V_{SS}.
16	REF OUT	Reference Output. The internal +2.5 V reference is provided at this pin. This is a single-ended output which is referred to AGND.
17	I_{OUT}	AD7710 Only. Compensation Current Output. A 20 μA constant current is provided at this pin. This current can be used in conjunction with an external thermistor to provide cold junction compensation.
17	AIN2	AD7712 Only. Analog Input Channel 2. High level analog input which accepts an analog input voltage range of $\pm 4 \times V_{REF}$/GAIN. At the nominal V_{REF} of +2.5 V and a gain of 1, the AIN2 input voltage range is ±10 V.
18	AGND	Ground reference point for analog circuitry.

Pin	Mnemonic	Function
19	$\overline{TFS}$	Transmit Frame Synchronization. Active low logic input used to write serial data to the device with serial data expected after the falling edge of this pulse. In the self-clocking mode, the serial clock becomes active after $\overline{TFS}$ goes low. In the external clocking mode, $\overline{TFS}$ must go low before the first bit of the data word is written to the part.
20	$\overline{RFS}$	Receive Frame Synchronization. Active low logic input used to access serial data from the device. In the self-clocking mode, the SCLK and SDATA lines both become active after $\overline{RFS}$ goes low. In the external clocking mode, the SDATA line becomes active after $\overline{RFS}$ goes low.
21	$\overline{DRDY}$	Logic output. A falling edge indicates that a new output word is available for transmission. The $\overline{DRDY}$ pin will return high upon completion of transmission of a full output word. $\overline{DRDY}$ is also used to indicate when the AD7710/AD7712 has completed its on-chip calibration sequence.
22	SDATA	Serial Data. Input/Output with serial data being written to the control register or the calibration registers and serial data being accessed from the control register, calibration registers or the data register. During an output data read operation, serial data becomes active after $\overline{RFS}$ goes low (provided $\overline{DRDY}$ is low). During a write operation, valid serial data is expected on the rising edges of SCLK when $\overline{TFS}$ is low. The output data coding is natural binary for unipolar inputs and offset binary for bipolar inputs.
23	DV_{DD}	Digital Supply Voltage, +5 V. DV_{DD} should never exceed AV_{DD} by more than 0.3 V. If DV_{DD} powers up before AV_{DD}, or if DV_{DD} can exceed AV_{DD} by more than 0.3 V at any other time, the protection scheme outlined in Figure 5 should be used.
24	DGND	Ground reference point for digital circuitry.

TERMINOLOGY

INTEGRAL NONLINEARITY

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full-scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

POSITIVE FULL-SCALE ERROR

Positive full-scale error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal input full-scale voltage. For AIN(+),* the ideal full-scale input voltage is (AIN(−) + V_{REF}/GAIN −3/2 LSBs); for AIN2 of AD7712, the ideal full-scale voltage is +4 × V_{REF}/GAIN −3/2 LSBs. Positive full-scale error applies to both unipolar and bipolar analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar offset error is the deviation of the first code transition from the ideal input voltage. For AIN(+), the ideal input voltage is (AIN(−) +0.5 LSB); for AIN2 of AD7712, the ideal input is 0.5 LSB when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal input voltage. For AIN(+), the ideal input voltage is (AIN(−) −0.5 LSB); for AIN2 of AD7712, the ideal input voltage is −0.5 LSB when operating in the bipolar mode.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal input voltage. For AIN(+), the ideal input voltage is (AIN(−) −V_{REF}/GAIN + 0.5 LSB); for AIN2 of AD7712, the ideal input voltage is (−4 × V_{REF}/GAIN+0.5 LSB) when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive full-scale overrange is the amount of overhead available to handle input voltages on AIN(+) input greater than (AIN(−)+V_{REF}/GAIN) or on AIN2 of AD7712 of greater than +4 × V_{REF}/GAIN (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages on AIN(+) below (AIN(−)−V_{REF}/GAIN) or on AIN2 of AD7712 below −4 × V_{REF}/GAIN without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks on AIN1(+) even in the unipolar mode provided that AIN(+) is greater than AIN(−) and greater than V_{SS} −30 mV.

OFFSET CALIBRATION RANGE

In the system calibration modes, the AD7710/AD7712 calibrates its offset with respect to the analog input. The offset calibration range specification defines the range of voltages that the AD7710/AD7712 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7710/AD7712 can accept in the system calibration mode and still calibrate full scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7710/AD7712's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full-scale that the AD7710/AD7712 can accept and still calibrate gain accurately.

*AIN(+) refers to AIN1(+) and AIN2(+) of AD7710 and AIN1(+) of AD7712. AIN(−) refers to AIN1(−) and AIN2(−) of AD7710 and AIN1(−) of AD7712.

CONTROL REGISTER (24 BITS)

A write to the device with the A0 input low writes data to the control register. A read to the device with the A0 input low accesses the contents of the control register. The control register is 24-bits wide and when writing to the register 24 bits of data must be written otherwise the data will not be loaded to the control register. In other words, it is not possible to write just the first 12-bits of data into the control register. If more than 24 clock pulses are provided before $\overline{TFS}$ returns high, then all clock pulses after the 24th clock pulse are ignored. Similarly, a read operation from the control register should access 24 bits of data.

MSB

MD2	MD1	MD0	G2	G1	G0	CH	PD	WL	IO[1]	BO	B/U

FS11[2]	FS10	FS9	FS8	FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0

LSB

[1]Don't Care on AD7712.
[2]Must always be 0 to ensure correct operation of the part.

Operating Mode			
MD2	**MD1**	**MD0**	**Operating Mode**
0	0	0	Normal Mode. This is the normal mode of operation of the device whereby a read to the device accesses data from the data register. This is the default condition of these bits after the internal power-on reset.
0	0	1	Activate Self-Calibration. This activates self-calibration on the channel selected by CH. This is a one-step calibration sequence, and when complete the part returns to Normal Mode (with MD2, MD1, MD0 of the control registers returning to 0,0,0). The $\overline{DRDY}$ output indicates when this self-calibration is complete and valid data is available in the output register. For this calibration type, the zero scale calibration is done internally on shorted (zeroed) inputs and the full-scale calibration is done on V_{REF}.
0	1	0	Activate System Calibration. This activates system calibration on the channel selected by CH. This is a two-step calibration sequence, with the zero scale calibration done first on the selected input channel and $\overline{DRDY}$ indicating when this zero scale calibration is complete. The part returns to Normal Mode at the end of this first step in the two-step sequence.
0	1	1	Activate System Calibration. This is the second step of the system calibration sequence with full-scale calibration being performed on the selected input channel. Once again, $\overline{DRDY}$ indicates when this full-scale calibration is complete. When this calibration is complete, the part returns to Normal Mode.
1	0	0	Activate System-Offset Calibration. This activates system-offset calibration on the channel selected by CH. This is a one-step calibration sequence and when complete the part returns to Normal Mode with $\overline{DRDY}$ indicating when this system offset calibration is complete. For this calibration type, the zero scale calibration is done on the selected input channel and the full-scale calibration is done internally on V_{REF}.
1	0	1	Activate Background Calibration. This activates background calibration on the channel selected by CH. If the background calibration mode is on, then the AD7710/AD7712 provides continuous self-calibration of the reference and shorted (zeroed) inputs. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the device when there is a change in the ambient temperature. In this mode, shorted (zeroed) inputs and V_{REF}, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are automatically updated.
1	1	0	Read/Write Zero-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the zero scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the zero scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits regardless, of the status of the WL bit of the control register. Therefore, when writing to the calibration register, 24 bits of data must be written, otherwise the new data will not be transferred to the calibration register.
1	1	1	Read/Write Full-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the full-scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the full-scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register. Therefore, when writing to the calibration register, 24 bits of data must be written, otherwise the new data will not be transferred to the calibration register.

Filter Selection (FS11–FS0)

The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$) filter response. The 12 bits of data programmed into these bits determine the filter cutoff frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device.

The first notch of the filter occurs at a frequency determined by the relationship: filter first notch frequency = $(f_{CLK\ IN}/512)/code$ where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 2,000. With the nominal $f_{CLK\ IN}$ of 10 MHz, this results in a first notch frequency range from 9.76 Hz to 1.028 kHz. To ensure correct operation of the part, the value of the code loaded to these bits must be within this range. Failure to do this will result in unspecified operation of the device.

Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I and II show the effect of the filter notch frequency and gain on the effective resolution of the part. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 50 Hz, then a new word is available at a 50 Hz rate or every 20 ms. If the first notch is at 1 kHz, a new word is available every 1 ms.

The settling time of the filter to a full-scale step input change is worst case 4 × 1/(output data rate). This settling time is to 100% of the final value. For example, with the first filter notch at 50 Hz, the settling time of the filter to a full-scale step input change is 80 ms max. If the first notch is at 1 kHz, the settling time of the filter to a full-scale input step is 4 ms max. This settling time can be reduced to 3 × 1/(output data rate) by synchronizing the step input change to a reset of the digital filter. In other words, if the step input takes place with $\overline{SYNC}$ low, the settling time will be 3 × 1/(output data rate). If a change of channel takes place, the settling time is 3 × 1/(output data rate) regardless of the $\overline{SYNC}$ input, but $\overline{DRDY}$ does not stay high for 3 × 1/output rate.

The −3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter −3 dB frequency = 0.262 × first notch frequency, but $\overline{DRDY}$ does not stay high for 3 × 1/output rate.

Tables I and II show the output rms noise for some typical notch and −3 dB frequencies. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. These numbers are typical and are generated with an analog input voltage of 0 V. The output noise from the part comes from two sources. First, there is the electrical noise in the semiconductor devices used in the implementation of the modulator (device noise). Secondly, when the analog input signal is converted into the digital domain, quantization noise is added. The device noise is at a low level and is largely independent of frequency. The quantization noise starts at an even lower level but rises rapidly with increasing frequency to become the dominant noise source. Consequently, lower filter notch settings (below 60 Hz approximately) tend to be device noise dominated while higher notch settings are dominated by quantization noise. Changing the filter notch and cutoff frequency in the quantization noise dominated region results in a more dramatic improvement in noise performance than it does in the device noise dominated region as shown in Table I. Furthermore, quantization noise is added after the PGA, so effective resolution is independent of gain for the higher filter notch frequencies. Meanwhile, device noise is added in the PGA, and therefore effective resolution suffers a little at high gains for lower notch frequencies.

At the lower filter notch settings (below 60 Hz), the no missing codes performance of the device is at the 24-bit level. At the higher settings, more codes will be missed until at 1 kHz notch setting, no missing codes performance is only guaranteed to the 12-bit level. However, since the effective resolution of the part is 10.5 bits for this filter notch setting, this no missing codes performance should be more than adequate for all applications.

The effective resolution of the device is defined as the ratio of the output rms noise to the input full scale. This does not remain constant with increasing gain or with increasing bandwidth. Table II shows the same table as Table I except that the output is now expressed in terms of effective resolution (the magnitude of the rms noise with respect to 2 × V_{REF}/GAIN, i.e., the input full scale). It is possible to do post filtering on the device to improve the output data rate for a given −3 dB frequency and also to further reduce the output noise (see Digital Filtering section).

Table I. Output Noise vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate[1]	−3 dB Frequency	Typical Output RMS Noise (μV)							
		Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz[2]	2.62 Hz	1.7	1.0	0.5	0.36	0.36	0.36	0.36	0.36
25 Hz[2]	6.55 Hz	4.9	2.2	1.2	0.6	0.36	0.36	0.36	0.36
30 Hz[2]	7.86 Hz	6.1	2.4	1.2	0.84	0.5	0.36	0.36	0.36
50 Hz[2]	13.1 Hz	7.5	3.8	2.0	1.0	0.6	0.5	0.5	0.45
60 Hz[2]	15.72 Hz	8.5	4.0	2.0	1.0	0.6	0.5	0.5	0.45
100 Hz[3]	26.2 Hz	13	6.4	3.7	1.8	1.1	0.9	0.65	0.65
250 Hz[3]	65.5 Hz	130	75	25	12	7.5	4	2.7	1.7
500 Hz[3]	131 Hz	0.6 × 10^3	0.26 × 10^3	140	70	35	25	15	8
1 kHz[3]	262 Hz	3.1 × 10^3	1.6 × 10^3	0.7 × 10^3	0.29 × 10^3	180	120	70	40

NOTES
[1]The default condition (after the internal power-on reset) for the first notch of filter is 60 Hz.
[2]For these filter notch frequencies, the output rms noise is primarily dominated by device noise and as a result is independent of the value of the reference voltage. Therefore, increasing the reference voltage will give an increase in the effective resolution of the device (i.e., the ratio of the rms noise to the input full scale is increased since the output rms noise remains constant as the input full-scale increases).
[3]For these filter notch frequencies, the output rms noise is dominated by quantization noise and as a result is proportional to the value of the reference voltage.

Table II. Effective Resolution vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate	−3 dB Frequency	Effective Resolution[1] (Bits)							
		Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz	2.62 Hz	21.5	21.5	21.5	20.5	19.5	18.5	17.5	16.5
25 Hz	6.55 Hz	20	20	20	20	19.5	18.5	17.5	16.5
30 Hz	7.86 Hz	19.5	20	20	19.5	19.5	18.5	17.5	16.5
50 Hz	13.1 Hz	19.5	19.5	19.5	19.5	19	18.5	17.5	16.5
60 Hz	15.72 Hz	19	19.5	19.5	19.5	19	18.5	17.5	16.5
100 Hz	26.2 Hz	18.5	18.5	18.5	18.5	18	17.5	17	16
250 Hz	65.5 Hz	15	15	15.5	15.5	15.5	15.5	15	14.5
500 Hz	131 Hz	13	13	13	13	13	12.5	12.5	12.5
1 kHz	262 Hz	10.5	10.5	11	11	11	10.5	10	10

NOTE
[1]Effective resolution is defined as the magnitude of the output rms noise with respect to the input full scale (i.e., 2 × V_{REF}/GAIN). The above table applies for a V_{REF} of +2.5 V and resolution numbers are rounded to the nearest 0.5 LSB.

CIRCUIT DESCRIPTION

The AD7710/AD7712 is a sigma-delta A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those in industrial control or process control applications. It contains a sigma-delta (or charge balancing) ADC, a calibration microcontroller with on-chip static RAM, a clock oscillator, a digital filter and a bidirectional serial communications port.

The part contains two programmable gain analog input channels. The gain range on both inputs is from 1 to 128. For the differential inputs, this means that the input can accept unipolar signals of between 0 mV to +20 mV and 0 mV to +2.5 V or bipolar signals in the range from ±20 mV to ±2.5 V when the reference input voltage equals +2.5 V. The input voltage range for the AIN2 input of the AD7712 is $\pm 4 \times V_{REF}/GAIN$ and is ±10 V with the nominal reference of +2.5 V and a gain of 1. The input signal to the selected analog input channel is continuously sampled at a rate determined by the frequency of the master clock, CLK IN, and the selected gain (see Table III). A charge balancing A/D converter (Sigma-Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. The programmable gain function on the analog input is also incorporated in this sigma-delta modulator with the input sampling frequency being modified to give the higher gains. A $sinc^3$ digital low-pass filter processes the output of the sigma-delta modulator and updates the output register at a rate determined by the first notch frequency of this filter. The output data can be read from the serial port randomly or periodically at any rate up to the output register update rate. The first notch of this digital filter (and hence its −3 dB frequency) can be programmed via an on-chip control register. The programmable range for this first notch frequency is from 9.76 Hz to 1.028 kHz, giving a programmable range for the −3 dB frequency of 2.58 Hz to 269 Hz.

The AD7710/AD7712 provides a number of calibration options which can be programmed via the on-chip control register. A calibration cycle may be initiated at any time by writing to this control register. The part can perform self-calibration using the on-chip calibration microcontroller and SRAM to store calibration parameters. Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel using the system calibration mode. Another option is a background calibration mode where the part continuously performs self-calibration and updates the calibration coefficients. Once the part is in this mode, the user does not have to worry about issuing periodic calibration commands to the device or asking the device to recalibrate when there is a change in the ambient temperature or power supply voltage.

The AD7710/AD7712 gives the user access to the on-chip calibration registers allowing the microprocessor to read the device's calibration coefficients and also to write its own calibration coefficients to the part from prestored values in E^2PROM. This gives the microprocessor much greater control over the part's calibration procedure. It also means that the user can verify that the device has performed its calibration correctly by comparing the coefficients after calibration with prestored values in E^2PROM.

The AD7710/AD7712 can be operated in single supply systems provided that the analog input voltage on the differential inputs does not go more negative than −30 mV. For larger bipolar signals on the differential inputs, a V_{SS} of −5 V is required by the part. For battery operation or low power systems, the part offers a standby mode that reduces idle power consumption to typically 100 μW on AD7712 and 7 μW on AD7710.

The AD7710/AD7712 uses a second-order sigma-delta modulator and a digital filter that provides a rolling average of the sampled output. After power-up, or if there is a step change in the input voltage, there is a settling time that must elapse before valid data is obtained.

Input Sample Rate

The modulator sample frequency for the device remains at $f_{CLK\ IN}/512$ (19.5 kHz @ $f_{CLK\ IN}$ = 10 MHz) regardless of the selected gain. However, gains greater than ×1 are achieved by a combination of multiple input samples per modulator cycle and a scaling of the ratio of reference capacitor to input capacitor. As a result of the multiple sampling, the input sample rate of the device varies with the selected gain (see Table III). The effective input impedance is $1/C \cdot f_S$ where C is the input sampling capacitance and f_S is the input sample rate.

Table III. Input Sampling Frequency vs. Gain

Gain	Input Sampling Frequency (f_S)
1	$f_{CLK\ IN}/512$ (19.5 kHz @ $f_{CLK\ IN}$ = 10 MHz)
2	$2 \times f_{CLK\ IN}/512$ (39 kHz @ $f_{CLK\ IN}$ = 10 MHz)
4	$4 \times f_{CLK\ IN}/512$ (78 kHz @ $f_{CLK\ IN}$ = 10 MHz)
8	$8 \times f_{CLK\ IN}/512$ (156 kHz @ $f_{CLK\ IN}$ = 10 MHz)
16	$8 \times f_{CLK\ IN}/512$ (156 kHz @ $f_{CLK\ IN}$ = 10 MHz)
32	$8 \times f_{CLK\ IN}/512$ (156 kHz @ $f_{CLK\ IN}$ = 10 MHz)
64	$8 \times f_{CLK\ IN}/512$ (156 kHz @ $f_{CLK\ IN}$ = 10 MHz)
128	$8 \times f_{CLK\ IN}/512$ (156 kHz @ $f_{CLK\ IN}$ = 10 MHz)

DIGITAL FILTERING

The part's digital filter behaves like a similar analog filter, with a few minor differences.

First, since digital filtering occurs after the A-to-D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full-scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. To alleviate this problem, the part has over-range headroom built into the sigma-delta modulator and digital filter which allows overrange excursions of 5% above the analog input range. If noise signals are larger than this, consideration should be given to analog input filtering, or to reducing the input channel voltage so that its full-scale is half that of the analog input channel full-scale. This will provide an overrange capability greater than 100% at the expense of reducing the dynamic range by 1 bit (50%).

Filter Characteristics

The cutoff frequency of the digital filter is determined by the value loaded to bits FS0 to FS11 in the control register. At the maximum clock frequency of 10 MHz, the minimum cutoff frequency of the filter is 2.58 Hz while the maximum programmable cutoff frequency is 269 Hz.

Figure 2 shows the filter frequency response for a cutoff frequency of 2.62 Hz which corresponds to a first filter notch frequency of 10 Hz. This is a $(\sin x/x)^3$ response (also called sinc^3) that provides >100 dB of 50 Hz and 60 Hz rejection. Programming a different cutoff frequency via FS0–FS11 does not alter the profile of the filter response, it changes the frequency of the notches as outlined in the Control Register section.

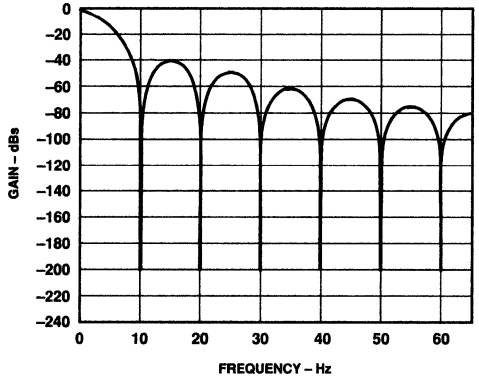

Figure 2. Frequency Response of AD7710/AD7712 Filter

Since the AD7710/AD7712 contains this on-chip, low-pass filtering, there is a settling time associated with step function inputs and data on the output will be invalid after a step change until the settling time has elapsed. The settling time depends upon the notch frequency chosen for the filter. The output data rate equates to this filter notch frequency and the settling time of the filter to a full-scale step input is 4 times the output data period. In applications using both input channels, the settling time of the filter must be allowed to elapse before data from the second channel is accessed.

Post Filtering

The on-chip modulator provides samples at a 19.5 kHz output rate. The on-chip digital filter decimates these samples to provide data at an output rate which corresponds to the programmed first notch frequency of the filter. Since the output data rate exceeds the Nyquist criterion, the output rate for a given bandwidth will satisfy most application requirements. However, there may be some applications which require a higher data rate for a given bandwidth and noise performance. Applications which need this higher data rate will require some post filtering following the digital filter of the AD7710/AD7712.

For example, if the required bandwidth is 7.86 Hz but the required update rate is 100 Hz, the data can be taken from the AD7710/AD7712 at the 100 Hz rate giving a −3 dB bandwidth of 26.2 Hz. Post filtering can be applied to this to reduce the bandwidth and output noise, to the 7.86 Hz bandwidth level, while maintaining an output rate of 100 Hz.

Post filtering can also be used to reduce the output noise from the device for bandwidths below 2.62 Hz. At a gain of 128, the output rms noise is 420 nV. This is essentially device noise or white noise, and since the input is chopped, the noise has a flat frequency response. By reducing the bandwidth below 2.62 Hz, the noise in the resultant passband can be reduced. A reduction in bandwidth by a factor of 2 results in a $\sqrt{2}$ reduction in the output rms noise. This additional filtering will result in a longer settling time.

Antialias Considerations

The digital filter does not provide any rejection at integer multiples of the modulator sample frequency (n × 19.5 kHz, where n = 1, 2, 3 . . .). This means that there are frequency bands, $\pm f_{3\ dB}$ wide ($f_{3\ dB}$ is cutoff frequency selected by FS0 to FS11) where noise passes unattenuated to the output. However, due to the AD7710/AD7712's high oversampling ratio, these bands occupy only a small fraction of the spectrum and most broadband noise is filtered. In any case, because of the high oversampling ratio a simple, RC, single pole filter is generally sufficient to attenuate the signals in these bands on the analog input and thus provide adequate antialiasing filtering.

If passive components are placed in front of the differential inputs, care must be taken to ensure that the source impedance is low enough so as not to introduce gain errors in the system. The dc input impedance for the differential inputs is over 1 GΩ. The input appears as a dynamic load which varies with the clock frequency and with the selected gain (see Figure 3). The input sample rate, as shown in Table III, determines the time allowed for the analog input capacitor, C_{IN}, to be charged. External impedances result in a longer charge time for this capacitor and this may result in gain errors being introduced on the analog inputs. Table IV shows the allowable external resistance/capacitance values such that no gain error to the 16-bit level is introduced while Table V shows the allowable external resistance/capacitance values such that no gain error to the 20-bit level is introduced. Both inputs of the differential input channels look into similar input circuitry.

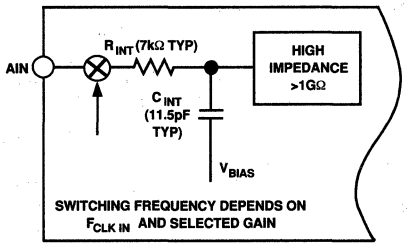

Figure 3. Differential Inputs Impedance

Table IV. Typical External Series Resistance Which Will Not Introduce 16-Bit Gain Error

Gain	External Capacitance (pF)					
	0	50	100	500	1000	5000
1	184 kΩ	45.3 kΩ	27.1 kΩ	7.3 kΩ	4.1 kΩ	1.1 kΩ
2	88.6 kΩ	22.1 kΩ	13.2 kΩ	3.6 kΩ	2.0 kΩ	560 Ω
4	41.4 kΩ	10.6 kΩ	6.3 kΩ	1.7 kΩ	970 Ω	270 Ω
8–128	17.6 kΩ	4.8 kΩ	2.9 kΩ	790 Ω	440 Ω	120 Ω

Table V. Typical External Series Resistance Which Will Not Introduce 20-Bit Gain Error

Gain	External Capacitance (pF)					
	0	50	100	500	1000	5000
1	145 kΩ	34.5 kΩ	20.4 kΩ	5.2 kΩ	2.8 kΩ	700 Ω
2	70.5 kΩ	16.9 kΩ	10 kΩ	2.5 kΩ	1.4 kΩ	350 Ω
4	31.8 kΩ	8.0 kΩ	4.8 kΩ	1.2 kΩ	670 Ω	170 Ω
8–128	13.4 kΩ	3.6 kΩ	2.2 kΩ	550 Ω	300 Ω	80 Ω

The numbers in the above tables assume a full-scale change on the analog input. In any case, the error introduced due to longer charging times is a gain error which can be removed using the system calibration capabilities of the AD7710/AD7712 provided that the resultant span is within the span limits of the system calibration techniques for the AD7710/AD7712.

The AIN2 input of the AD7712 contains a resistive attenuation network as outlined in Figure 4. The typical input impedance on this input is 44 kΩ. As a result, the AIN2 input of the AD7712 should be driven from a low impedance source.

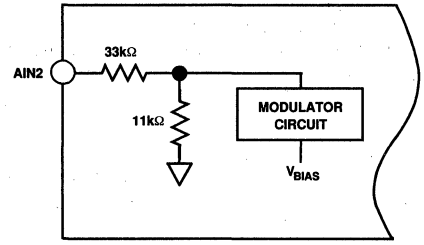

Figure 4. AIN2 of AD7712 Input Impedance

ANALOG INPUT FUNCTIONS

Analog Input Ranges

The analog inputs on the AD7710/AD7712 provide the user with considerable flexibility in terms of analog input voltage ranges. One of the inputs is a differential, programmable gain, input channel which can handle either unipolar or bipolar input signals. The common mode range of this input is from V_{SS} to AV_{DD} provided that the absolute value of the analog input voltage lies between V_{SS} −30 mV and AV_{DD}+30 mV. The second analog input is a single-ended, programmable gain high level input which accepts analog input ranges of 0 to +4 × V_{REF}/GAIN or ±4 × V_{REF}/GAIN.

The dc input leakage current on the AIN1 input is 10 pA maximum at 25°C (±1 nA over temperature). This results in a dc offset voltage developed across the source impedance. However, this dc offset effect can be compensated for by a combination of the differential input capability of the part and its system calibration mode. The dc input current on the AIN2 input depends on the input voltage, For the nominal input voltage range of ±10 V, the input current is ±225 μA typ.

Burn-Out Current

The AIN1(+) input of the AD7710/AD7712 contains a 1 μA current source which can be turned on/off via the control register. This current source can be used in checking that a transducer has not burnt-out or gone open circuit before attempting to take measurements on that channel. If the current is turned on and is allowed flow into the transducer and a measurement of the input voltage on the AIN1 input is taken, it can indicate that the transducer is not functioning correctly. For normal operation, this burn-out current is turned off by writing a 0 to the BO bit in the control register.

Bipolar/Unipolar Inputs

The two analog inputs on the AD7710/AD7712 can accept either unipolar or bipolar input voltage ranges. Bipolar or unipolar options are chosen by programming the B/U bit of the control register. This programs both channels for either unipolar or bipolar operation. Programming the part for either unipolar or bipolar operation does not change any of the input signal conditioning; it simply changes the data output coding. The data coding is binary for unipolar inputs and offset binary for bipolar inputs.

Both analog inputs on the AD7710 and the AIN1 input channel of the AD7712 are differential and, as a result, the voltage to which the unipolar and bipolar signals are referenced is the voltage on the AIN(−) input. For example, if AIN(−) is +1.25 V and the part is configured for unipolar operation with a gain of 1 and a V_{REF} of +2.5 V, the input voltage range on the AIN(+) input is +1.25 V to +3.75 V. If AIN(−) is +1.25 V and the part is configured for bipolar mode with a gain of 1 and a V_{REF} of +2.5 V, the analog input range on the AIN(+) input is −1.25 V to +3.75 V. For the AIN2 input of the AD7712, the input signals are referenced to AGND.

REFERENCE INPUT/OUTPUT

The AD7710/AD7712 contains a temperature compensated +2.5 V reference which has an initial tolerance of ±4%. This reference voltage is provided at the REF OUT pin and it can be used as the reference voltage for the part by connecting the REF OUT pin to the REF IN(+) pin. This REF OUT pin is a single-ended output, referenced to AGND, which is capable of providing up to 1mA to an external load. In applications where REF OUT is connected directly to REF IN(+), REF IN(−) should be tied to AGND to provide the nominal +2.5 V reference for the AD7710/AD7712.

The reference inputs of the AD7710/AD7712, REF IN(+) and REF IN(−), provide a differential reference input capability. The common mode range for these differential inputs is from V_{SS} to AV_{DD}. The nominal differential voltage, V_{REF} (REF IN(+)−REF IN(−)), is +2.5 V for specified operation, but the reference voltage can go to +5 V with no degradation in performance provided that the absolute value of REF IN(+) and REF IN(−) does not exceed its AV_{DD} and V_{SS} limits and the V_{BIAS} input voltage range limits are obeyed. The part is also functional with V_{REF} voltages down to 1 V but with degraded performance as the output noise will, in terms of LSB size, be larger. REF IN(+) must always be greater than REF IN(−) for correct operation of the AD7710/AD7712.

Both reference inputs provide a high impedance, dynamic load similar to the AIN1 analog input. The maximum dc input leakage current is 10 pA (±1 nA over temperature) and source resistance may result in gain errors on the part. The reference inputs look like the AIN1 analog input (see Figure 7). In this case, R_{INT} is 5 kΩ typ and C_{INT} varies with gain. The input sample rate is $f_{CLK\ IN}$/512 and does not vary with gain. For gains of 1 to 8 C_{INT} is 20 pF; for a gain of 16 it is 10 pF; for a gain of 32 it is 5 pF; for a gain of 64 it is 2.5 pF, and for a gain of 128 it is 1.25 pF.

The digital filter of the part removes noise from the reference input just as it does with the analog input, and the same limitations apply regarding lack of noise rejection at integer multiples of the sampling frequency. The output noise performance outlined in Tables I and II assumes a clean reference. If the reference noise in the bandwidth of interest is excessive, it can degrade the performance of the AD7710/AD7712. Using the on-chip reference as the reference source for the part (i.e., connecting REF OUT to REF IN) results in somewhat degraded output noise performance from the AD7710/AD7712 for portions of the noise table that are dominated by the device noise. The on-chip reference noise effect is eliminated in ratiometric applications where the reference is used to provide its excitation voltage for the analog front end. Recommended reference voltage sources for the AD7710/AD7712 include the AD780 and AD680 2.5 V references.

V_{BIAS} Input

The V_{BIAS} input determines at what voltage the internal analog circuitry is biased. It essentially provides the return path for analog currents flowing in the modulator and, as such, it should be driven from a low impedance point to minimize errors.

For maximum internal headroom, the V_{BIAS} voltage should be set halfway between AV_{DD} and V_{SS}. The difference between AV_{DD} and (V_{BIAS} + 0.85 × V_{REF}) determines the amount of headroom which the circuit has at the upper end while the difference between V_{SS} and (V_{BIAS} − 0.85 × V_{REF}) determines the amount of headroom the circuit has at the lower end. Care should be taken in choosing a V_{BIAS} voltage to ensure that is stays within prescribed limits. For single +5 V operation, the selected V_{BIAS} voltage must ensure that V_{BIAS} ± 0.85 × V_{REF} does not exceed AV_{DD} or V_{SS} or that the V_{BIAS} voltage itself is greater than V_{SS} + 2.1 V and less than AV_{DD} − 2.1 V. For single +10 V operation or dual ±5 V operation, the selected V_{BIAS} voltage must ensure that V_{BIAS} ± 0.85 × V_{REF} does not exceed AV_{DD} or V_{SS} or that the V_{BIAS} voltage itself is greater than V_{SS} + 3 V or less than AV_{DD} − 3 V. For example, with AV_{DD} = +4.75 V, V_{SS} = 0 V and V_{REF} = +2.5 V, the allowable range for the V_{BIAS} voltage is +2.125 V to +2.625 V. With AV_{DD} = +9.5 V, V_{SS} = 0 V and V_{REF} = +5 V, the range for V_{BIAS} is +4.25 V to +5.25 V. With AV_{DD} = +4.75 V, V_{SS} = −4.75 V and V_{REF} = +2.5 V, the V_{BIAS} range is −2.625 V to +2.625 V.

The V_{BIAS} voltage does have an effect on the AV_{DD} power supply rejection performance of the AD7710/AD7712. If the V_{BIAS} voltage tracks the AV_{DD} supply, it improves the power supply rejection from the AV_{DD} supply line from 80 dB to 95 dB. Using an external Zener diode, connected between the AV_{DD} line and V_{BIAS}, as the source for the V_{BIAS} voltage gives the improvement in AV_{DD} power supply rejection performance.

USING THE AD7710/AD7712: SYSTEM DESIGN CONSIDERATIONS

The AD7710/AD7712 operates differently from successive approximation ADCs or integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The output register is updated at a rate determined by the first notch of the filter and the output can be read at any time, either synchronously or asynchronously.

Clocking

The AD7710/AD7712 requires a master clock input, which may be an external TTL/CMOS compatible clock signal applied to the MCLK IN pin with the MCLK OUT pin left unconnected. Alternatively, a crystal of the correct frequency can be connected between MCLK IN and MCLK OUT, in which case the clock circuit will function as a crystal controlled oscillator. For lower clock frequencies, a ceramic resonator may be used instead of the crystal. For these lower frequency oscillators, external capacitors may be required on either the ceramic resonator or on the crystal.

The input sampling frequency, the modulator sampling frequency, the −3 dB frequency, output update rate and calibration time are all directly related to the master clock frequency, $f_{CLK\ IN}$. Reducing the master clock frequency by a factor of 2 will halve the above frequencies and update rate and will double the calibration time.

The current drawn from the DV_{DD} power supply is also directly related to $f_{CLK\ IN}$. Reducing $f_{CLK\ IN}$ by a factor of 2 will halve the DV_{DD} current but will not affect the current drawn from the AV_{DD} power supply.

System Synchronization

If multiple AD7710/AD7712s are operated from a common master clock, they can be synchronized to update their output registers simultaneously. A falling edge on the $\overline{SYNC}$ input resets the filter and places the AD7710/AD7712 into a consistent, known state. A common signal to the AD7710/AD7712s' $\overline{SYNC}$ inputs will synchronize their operation. This would normally be done after each AD7710/AD7712 has performed its own calibration or has had calibration coefficients loaded to it.

The $\overline{SYNC}$ input can also be used to reset the digital filter in systems where the turn-on time of the digital power supply (DV_{DD}) is very long. In such cases, the AD7710/AD7712 will start operating internally before the DV_{DD} line has reached its minimum operating level, +4.75 V. With a low DV_{DD} voltage, the AD7710/AD7712's internal digital filter logic does not operate correctly. Thus, the AD7710/AD7712 may have clocked itself into an incorrect operating condition by the time that DV_{DD} has reached its correct level. The digital filter will be reset upon issue of a calibration command (whether it is self-calibration, system calibration or background calibration) to the AD7710/AD7712. This ensures correct operation of the AD7710/AD7712. In systems where the power-on default conditions of the AD7710/AD7712 are acceptable, and no calibration is performed after power-on, issuing a $\overline{SYNC}$ pulse to the AD7710/AD7712 will reset the AD7710/AD7712's digital filter logic. An R, C on the $\overline{SYNC}$ line, with R, C time constant longer than the DV_{DD} power-on time, will perform the $\overline{SYNC}$ function.

Accuracy

Sigma-Delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no missing codes performance. The AD7710/AD7712 achieves excellent linearity by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient. The device also achieves low input drift through the use of chopper stabilized techniques in its input stage. To ensure excellent performance over time and temperature, the AD7710/AD7712 uses digital calibration techniques that minimize offset and gain error.

Autocalibration

Autocalibration on the AD7710/AD7712 removes offset and gain errors from the device. A calibration routine should be initiated on the device whenever there is a change in the ambient operating temperature or supply voltage. It should also be initiated if there is a change in the selected gain, filter notch or bipolar/unipolar input range. However, if the AD7710/AD7712 is in its background calibration mode, the above changes are all automatically taken care of (after the settling time of the filter has been allowed for).

The AD7710/AD7712 offers self-calibration, system calibration and background calibration facilities. For calibration to occur on the selected channel, the on-chip microcontroller must record the modulator output for two different input conditions. These are "zero scale" and "full-scale" points. With these readings, the microcontroller can calculate the gain slope for the input to output transfer function of the converter. Internally, the part works with a resolution of 33 bits to determine its conversion result of either 16 bits or 24 bits.

The AD7710/AD7712 also provides the facility to write to the on-chip calibration registers and in this manner the span and offset for the part can be adjusted by the user. The offset calibration register contains a value which is subtracted from all conversion results, while the full-scale calibration register contains a value which is multiplied by all conversion results. The offset calibration coefficient is subtracted from the result prior to the multiplication by the full-scale coefficient. In the first three modes outlined here, the $\overline{\text{DRDY}}$ indicates that calibration is complete by going low. If $\overline{\text{DRDY}}$ is low before (or goes low during) the calibration command, it may take up to one modulator cycle before $\overline{\text{DRDY}}$ goes high to indicate that calibration is in progress. Therefore, the $\overline{\text{DRDY}}$ line should be ignored for up to one modulator cycle after the last bit of the calibration command is written to the control register.

Self-Calibration

In the self-calibration mode with a unipolar input range, the zero scale point used in determining the calibration coefficients is with both inputs shorted (i.e., AIN(+) = AIN(−) = V_{BIAS} for differential inputs and AIN = V_{BIAS} for single-ended inputs) and the full-scale point is V_{REF}. The zero scale coefficient is determined by converting an internal shorted inputs node. The full scale coefficient is determined from the span between this shorted inputs conversion and a conversion on an internal V_{REF} node. The self-calibration mode is invoked by writing the appropriate values (0, 0, 1) to the MD2, MD1 and MD0 bits of the control register. In this calibration mode, the shorted inputs node is switched in to the modulator first and a conversion is performed; the V_{REF} node is then switched in and another conversion is performed. When the calibration sequence is complete, the calibration coefficients updated and the filter resettled to the analog input voltage, the $\overline{\text{DRDY}}$ output goes low. The self-calibration procedure takes into account the selected gain on the PGA.

For bipolar input ranges in the self-calibrating mode, the sequence is very similar to that just outlined. In this case, the two points which the AD7710/AD7712 calibrates are midscale (bipolar zero) and positive full-scale.

System Calibration

System calibration allows the AD7710/AD7712 to compensate for system gain and offset errors as well as its own internal errors. System calibration performs the same slope factor calculations as self-calibration but uses voltage values presented by the system to the AIN inputs for the zero and full-scale points. System calibration is a two-step process. The zero scale point must be presented to the converter first. It must be applied to the converter before the calibration step is initiated and remain stable until the step is complete. System calibration is initiated by writing the appropriate values (0, 1, 0) to the MD2, MD1 and MD0 bits of the control register. The $\overline{\text{DRDY}}$ output from the device will signal when the step is complete by going low. After the zero scale point is calibrated, the full-scale point is applied and the second step of the calibration process is initiated by again writing the appropriate values (0, 1, 1) to MD2, MD1 and MD0. Again the full-scale voltage must be set up before the calibration is initiated and it must remain stable throughout the calibration step. $\overline{\text{DRDY}}$ goes low at the end of this second step to indicate that the system calibration is complete. In the unipolar mode, the system calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

This two-step system calibration mode offers another feature. After the sequence has been completed, additional offset or gain calibrations can be performed by themselves to adjust the zero reference point or the system gain. This is achieved by performing the first step of the system calibration sequence (by writing 0, 1, 0 to MD2, MD1, MD0). This will adjust the zero scale or offset point but will not change the slope factor from what was set during a full system calibration sequence.

System calibration can also be used to remove any errors from an antialiasing filter on the analog input. A simple R, C antialiasing filter on the front end may introduce a gain error on the analog input voltage but the system calibration can be used to remove this error.

System Offset Calibration

System offset calibration is a variation of both the system calibration and self-calibration. In this case, the zero scale point for the system is presented to the AIN input of the converter. System offset calibration is initiated by writing 1, 0, 0 to MD2, MD1, MD0. The system zero scale coefficient is determined by converting the voltage applied to the AIN input, while the full-scale coefficient is determined from the span between this AIN conversion and a conversion on V_{REF}. The zero scale point should be applied to the AIN input for the duration of the calibration sequence. This is a one step calibration sequence with $\overline{\text{DRDY}}$ going low when the sequence is completed. In the unipolar mode, the system offset calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

Background Calibration

The AD7710/AD7712 also offers a background calibration mode where the part interleaves its calibration procedure with its normal conversion sequence. In the background calibration mode, the same voltages are used as the calibration points as are used in the self-calibration mode, i.e., shorted inputs and V_{REF}. The background calibration mode is invoked by writing 1, 0, 1 to MD2, MD1, MD0 of the control register. When invoked, the background calibration mode reduces the output data rate of the

AD7710/AD7712 by a factor of six while the −3 dB bandwidth remains unchanged. Its advantage is that the part is continually performing calibration and automatically updating its calibration coefficients. As a result, the effects of temperature drift, supply sensitivity and time drift on zero and full scale errors are automatically removed. When the background calibration mode is turned on, the part will remain in this mode until bits MD2, MD1 and MD0 of the control register are changed. With background calibration mode on, the first result from the AD7710/AD7712 will be incorrect as the full-scale calibration will not have been performed. For a step change on the input, the second output update will have settled to 100% of the final value.

Table VI summarizes the calibration modes and the calibration points associated with them. It also gives the duration from when the calibration is invoked to when valid data is available to the user.

Table VI. Calibration Truth Table

Cal Type	MD2, MD1, MD0	Zero Scale Cal	Full-Scale Cal	Sequence	Duration
Self-Cal	0, 0, 1	Shorted Inputs	V_{REF}	One Step	9 × 1/Output Rate
System Cal	0, 1, 0	AIN	–	Two Step	4 × 1/Output Rate
System Cal	0, 1, 1	–	AIN	Two Step	4 × 1/Output Rate
System Offset Cal	1, 0, 0	AIN	V_{REF}	One Step	9 × 1/Output Rate
Background Cal	1, 0, 1	Shorted Inputs	V_{REF}	One Step	6 × 1/Output Rate

Span and Offset Limits

Whenever a system calibration mode is used, there are limits on the amount of offset and span that can be accommodated. The range of input span in both the unipolar and bipolar modes for both inputs on the AD7710 and AIN1 of the AD7712 has a minimum value of 0.8 × V_{REF}/GAIN and a maximum value of 2.1 × V_{REF}/GAIN. For AIN2 on the AD7712, both numbers are a factor of 4 higher.

The amount of offset that can be accommodated depends on whether the unipolar or bipolar mode is being used. This offset range is limited by the requirement that the positive full-scale calibration limit is ≤ 1.05 × V_{REF}/GAIN for the differential inputs. Therefore, the offset range plus the span range cannot exceed 1.05 × V_{REF}/GAIN for the differential inputs. If the span is at its minimum (0.8 × V_{REF}/GAIN) the maximum the offset can be is (0.25 × V_{REF}/GAIN) for the differential inputs. For AIN2 of AD7712, both ranges are multiplied by a factor of 4.

In the bipolar mode, the system offset calibration range is again restricted by the span range. The span range of the converter in bipolar mode is equidistant around the voltage used for the zero scale point thus the offset range plus half the span range cannot exceed (1.05 × V_{REF}/GAIN) for the differential inputs. If the span is set to 2 × V_{REF}/GAIN, the offset span cannot move more than ±(0.05 × V_{REF}/GAIN) before the endpoints of the transfer function exceed the input overrange limits ±(1.05 × V_{REF} /GAIN) for the differential inputs. If the span range is set to the minimum ±(0.4 × V_{REF}/GAIN) the maximum allowable offset range is ±(0.65 × V_{REF}/GAIN) for the differential inputs. Once again, for AIN2 of AD7712, both ranges are multiplied by a factor of 4.

POWER-UP AND CALIBRATION

On power-up, the AD7710/AD7712 performs an internal reset which sets the contents of the control register to a known state. However, to ensure correct calibration for the device a calibration routine should be performed after power-up.

The power dissipation and temperature drift of the AD7710/AD7712 are low and no warm-up time is required before the initial calibration is performed. However, if an external reference is being used, this reference must have stabilized before calibration is initiated.

Drift Considerations

The AD7710/AD7712 uses chopper stabilization techniques to minimize input offset drift. Charge injection in the analog switches and dc leakage currents at the sampling node are the primary sources of offset voltage drift in the converter. The dc input leakage current is essentially independent of the selected gain. Gain drift within the converter depends primarily upon the temperature tracking of the internal capacitors. It is not affected by leakage currents.

Measurement errors due to offset drift or gain drift can be eliminated at any time by recalibrating the converter or by operating the part in the background calibration mode. Using the system calibration mode can also minimize offset and gain errors in the signal conditioning circuitry. Integral and differential linearity errors are not significantly affected by temperature changes.

POWER SUPPLIES AND GROUNDING

Since the analog inputs and reference input are differential, most of the voltages in the analog modulator are common-mode voltages. V_{BIAS} provides the return path for most of the analog currents flowing in the analog modulator. As a result, the V_{BIAS} input should be driven from a low impedance to minimize errors due to charging/discharging impedances on this line. When the internal reference is used as the reference source for the part, AGND is the ground return for this reference voltage.

The analog and digital supplies to the AD7710/AD7712 are independent and separately pinned out to minimize coupling between the analog and digital sections of the device. The digital filter will provide rejection of broadband noise on the power supplies, except at integer multiples of the modulator sampling frequency. The digital supply (DV_{DD}) must never exceed the analog positive supply (AV_{DD}) by more than 0.3 V. Power supply sequencing therefore is important. If separate analog and digital supplies are used, care must be taken to ensure that the analog supply is powered up first. If this cannot be ensured or if DV_{DD} can exceed AV_{DD} at any other time, the protection scheme outlined in Figure 5 is recommended to protect the device. In systems where AV_{DD} = +5 V and DV_{DD} = +5 V, it is recommended that AV_{DD} and DV_{DD} are driven from the same +5 V supply, although each supply should be decoupled separately. It is preferable that the common supply is the system's analog +5 V supply.

It is also important that power is applied to the AD7710/AD7712 before signals at REF IN, AIN or the logic input pins in order to avoid latch-up. If separate supplies are used for the AD7710/AD7712 and the system digital circuitry, then the AD7710/AD7712 should be powered up first. If it is not possible to guarantee this, then current limiting resistors should be placed in series with the logic inputs.

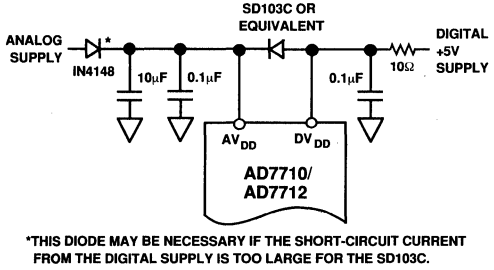

Figure 5. Protection Scheme for DV_{DD} Powering-Up Before AV_{DD}

DIGITAL INTERFACE

The AD7710/AD7712's serial communications port provides a flexible arrangement to allow easy interfacing to industry standard microprocessors, microcontrollers and digital signal processors. A serial read to the part can access data from the output register, the control register or from the calibration registers. A serial write to the part can write data to the control register or the calibration registers.

Two different modes of operation are available, optimized for different types of interface where the AD7710/AD7712 can act either as master in the system (it provides the serial clock) or as slave (an external serial clock can be provided to the AD7710/AD7712). These two modes, labelled self-clocking mode and external clocking mode, are discussed in detail in the following sections.

Self-Clocking Mode

The part is configured for its self-clocking mode by tying the MODE pin high. In this mode, the part provides the serial clock signal used for the transfer of data to and from the AD7710/AD7712. This self-clocking mode can be used with processors that allow an external device to clock their serial port including most digital signal processors and microcontrollers such as the 68HC11 and 68HC05. It also allows easy interfacing to serial parallel conversion circuits in systems with parallel data communication, allowing interfacing to 74XX299 Universal Shift registers without any additional decoding. In the case of shift registers, the serial clock line should have a pull-down resistor instead of the pull-up resistor shown in Figure 6 and Figure 7.

Read Operation

Data can be read from either the output register, the control register or the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for the duration of the serial read operation. With A0 high, data is accessed from either the output register or from the calibration registers. With A0 low, data is accessed from the control register.

The function of the $\overline{\text{DRDY}}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{\text{DRDY}}$ goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If data is not read from the output register, the $\overline{\text{DRDY}}$ line will remain low. The output register will continue to be updated at the output update rate but $\overline{\text{DRDY}}$ will not indicate this. A read from the device in this circumstance will access the most recent word in the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{\text{DRDY}}$ will not indicate this and the new data word will be lost to the user. $\overline{\text{DRDY}}$ is not affected by reading from the control register or the calibration registers.

Data can only be accessed from the output data register when $\overline{\text{DRDY}}$ is low. If $\overline{\text{RFS}}$ goes low with $\overline{\text{DRDY}}$ high, no data transfer will take place. $\overline{\text{DRDY}}$ does not have any effect on reading data from the control register or from the calibration registers.

Figures 6a and 6b show timing diagrams for reading from the part in the self-clocking mode. Figure 6a shows a situation where all the data is read from the part in one read operation. Figure 6b shows a situation where the data is read from the AD7710/AD7712 over a number of read operations. Both read operations show a read from the part's output data register. A read from the control register or calibration registers is similar but in these cases the $\overline{\text{DRDY}}$ line is not related to the read function. Depending on the output update rate, it can go low at any stage in the control/calibration register read cycle without affecting the read and its status should be ignored. A read operation from either the control or calibration registers must always read 24 bits of data from the respective register.

Figure 6a shows a read operation from the part where $\overline{\text{RFS}}$ remains low for the duration of the data word transmission. For the timing diagram shown, it is assumed that there is a pull-up resistor on the SCLK output. With $\overline{\text{DRDY}}$ low, the $\overline{\text{RFS}}$ input is brought low. $\overline{\text{RFS}}$ going low enables the serial clock of the AD7710/AD7712 and also places the MSB of the word on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The final active falling edge of SCLK clocks out the LSB and this LSB is valid prior to the final active rising edge of SCLK. Coincident with the next falling edge of SCLK, $\overline{\text{DRDY}}$ is reset high. $\overline{\text{DRDY}}$ going high turns off the SCLK and the SDATA outputs. This means that the data hold time for the LSB is slightly shorter than for all other bits.

Figure 6b shows a timing diagram for a read operation where $\overline{\text{RFS}}$ returns high during the transmission of the word and returns low again to access the rest of the data word. As before, the waveform for SCLK assumes that there is a pull-up resistor on this line. Timing parameters and functions are very similar to that outlined for Figure 6a, but Figure 6b has a number of additional times to show timing relationships when $\overline{\text{RFS}}$ returns high in the middle of transferring a word.

$\overline{\text{RFS}}$ should return high during a low time of SCLK. On the rising edge of $\overline{\text{RFS}}$, the SCLK and SDATA outputs are turned

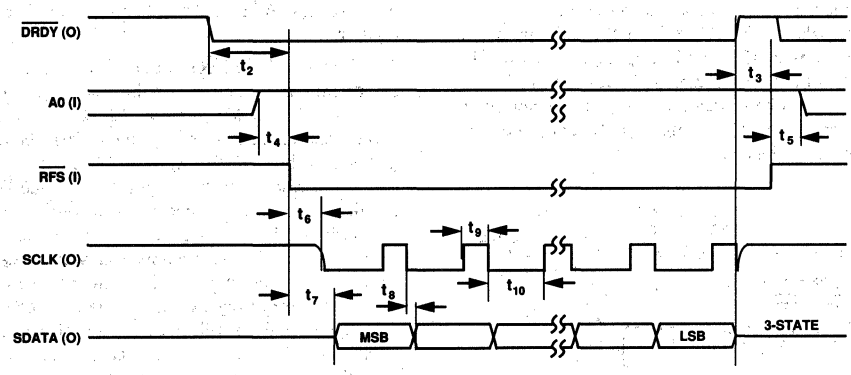

Figure 6a. Self-Clocking Mode, Output Data Read Operation

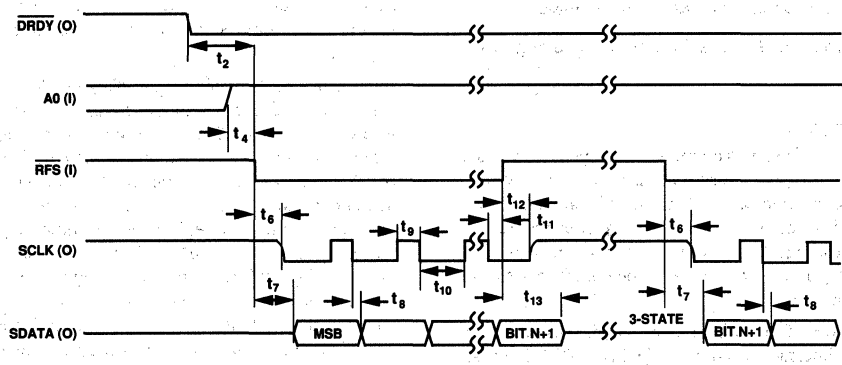

Figure 6b. Self-Clocking Mode, Output Data Read Operation (RFS Returns High During Read Operation)

off. DRDY remains low and will remain low until all bits of the data word are read from the part, regardless of the number of times RFS changes state during the read operation. Depending on the time between the falling edge of SCLK and the rising edge of RFS, the next bit (BIT N + 1) may appear on the data-bus before RFS goes high. When RFS returns low again, it turns on the SCLK output and activates the SDATA output. When the entire word is transmitted, the DRDY line will go high turning off the SDATA and SCLK lines as per Figure 6a.

Write Operation

Data can be written to either the control register or calibration registers. In either case, the write operation is not affected by the DRDY line and the write operation does not have any effect on the status of DRDY. A write operation to the control register or the calibration register must always write 24 bits to the respective register.

Figure 7a shows a write operation to the AD7710/AD7712 with TFS remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. The falling edge of TFS enables the internally generated SCLK output. The serial data to be loaded to the AD7710/AD7712 must be valid on the rising edge of this SCLK signal. Data is clocked into the AD7710/AD7712 on the rising edge of the SCLK signal with the MSB transferred first. On the last active high time of SCLK, the LSB is loaded to the AD7710/AD7712. Subsequent to the next falling edge of SCLK, the SCLK output is turned off. (The timing diagram of Figure 7a assumes a pull-up resistor on the SCLK line.)

Figure 7b shows a timing diagram for a write operation to the AD7710/AD7712 with TFS returning high during the write operation and returning low again to write the rest of the data word. Once again, the timing diagram of Figure 7b assumes a pull-up resistor on the SCLK output. Timing parameters and functions are very similar to that outlined for Figure 7a but Figure 7b has a number of additional times to show timing relationships when TFS returns high in the middle of transferring a word.

The falling edge of TFS again initiates the SCLK output and data to be loaded to the AD7710/AD7712 must be valid prior to the rising edge of this SCLK signal. The rising edge of TFS turns off the SCLK output. TFS should return high during the low time of SCLK. When TFS returns low again, it turns on the SCLK output. When all data bits have been written to the device, the SCLK output is turned off as per Figure 7a.

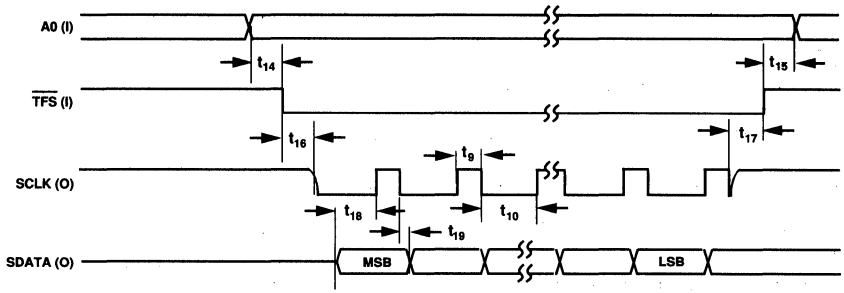

Figure 7a. Self-Clocking Mode, Control/Calibration Register Write Operation

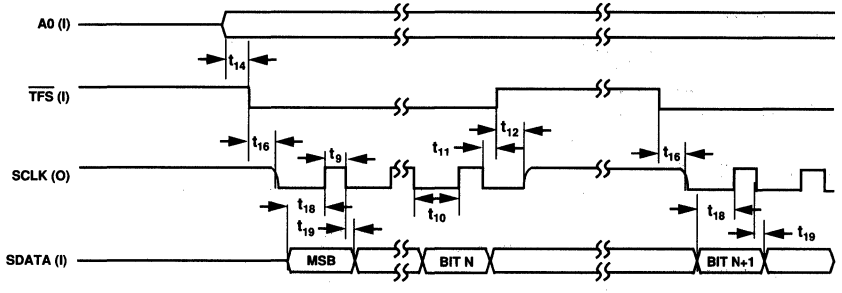

Figure 7b. Self-Clocking Mode, Control/Calibration Register Write Operation ($\overline{TFS}$ Returns High During Write Operation)

External Clocking Mode

The AD7710/AD7712 is configured for its external clocking mode by tying the MODE pin low. In this mode, SCLK of the part is configured as an input and an external serial clock must be provided to this SCLK pin. This external clocking mode is designed for direct interface to systems which provide a serial clock output that is synchronized to the serial data output, including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

Read Operation

As with the self-clocking mode, data can be read from either the output register, the control register or the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for the duration of the serial read operation. With A0 high, data is accessed from either the output register or from the calibration registers. With A0 low, data is accessed from the control register.

The function of the $\overline{DRDY}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{DRDY}$ goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If data is not read from the output register, the $\overline{DRDY}$ line will remain low. The output register will continue to be updated at the output update rate but $\overline{DRDY}$ will not indicate this. A read from the device in this circumstance will access the most recent word in the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{DRDY}$ will not indicate this and the new data word will be lost to the user. $\overline{DRDY}$ is not affected by reading from the control register or the calibration register.

Data can only be accessed from the output data register when $\overline{DRDY}$ is low. If $\overline{RFS}$ goes low while $\overline{DRDY}$ is high, no data transfer will take place. $\overline{DRDY}$ does not have any effect on reading data from the control register or from the calibration registers.

Figures 8a and 8b show timing diagrams for reading from the part's in the external clocking mode. Figure 8a shows a situation where all the data is read from the part in one read operation. Figure 8b shows a situation where the data is read from the part over a number of read operations. Both read operations show a read from the part's output data register. A read from the control register or calibration registers is similar but in these cases the $\overline{DRDY}$ line is not related to the read function. Depending on the output update rate, it can go low at any stage in the control/calibration register read cycle without affecting the read and its status should be ignored. A read operation from either the control or calibration registers must always read 24 bits of data from the respective register.

Figure 8a shows a read operation from the AD7710/AD7712 where $\overline{RFS}$ remains low for the duration of the data word transmission. With $\overline{DRDY}$ low, the $\overline{RFS}$ input is brought low. The input SCLK signal should be low between read and write operations. $\overline{RFS}$ going low places the MSB of the word to be read on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The penultimate falling edge of SCLK clocks out the LSB and the final falling edge resets the $\overline{DRDY}$ line high. This rising edge of $\overline{DRDY}$ turns off the serial data output.

Figure 8b shows a timing diagram for a read operation where $\overline{RFS}$ returns high during the transmission of the word and returns low again to access the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 8a but Figure 8b has a number of additional times to show timing relationships when $\overline{RFS}$ returns high in the middle of transferring a word.

$\overline{RFS}$ should return high during a low time of SCLK. On the rising edge of $\overline{RFS}$, the SDATA output is turned off. $\overline{DRDY}$ remains low and will remain low until all bits of the data word are read from the part, regardless of the number of times $\overline{RFS}$ changes state during the read operation. Depending on the time between the falling edge of SCLK and the rising edge of $\overline{RFS}$, the next bit (BIT N + 1) may appear on the databus before $\overline{RFS}$ goes high. When $\overline{RFS}$ returns low again, it activates the SDATA output. When the entire word is transmitted, the $\overline{DRDY}$ line will go high, turning off the SDATA output as per Figure 8a.

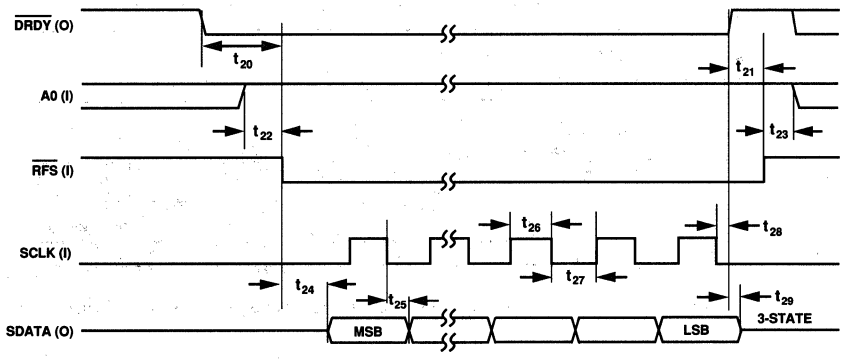

Figure 8a. External Clocking Mode, Output Data Read Operation

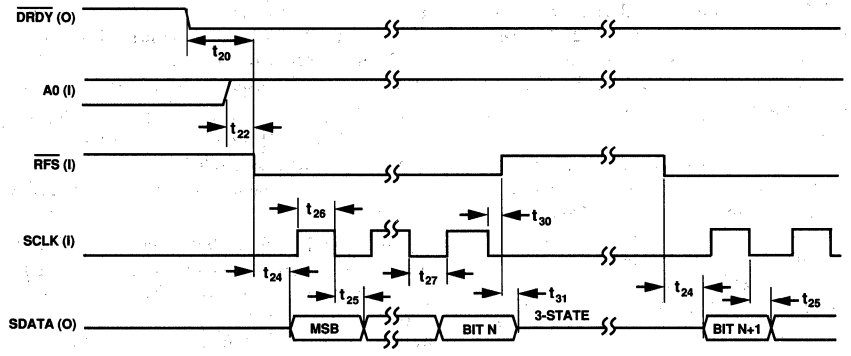

Figure 8b. External Clocking Mode, Output Data Read Operation ($\overline{RFS}$ Returns High During Read Operation)

Write Operation

Data can be written to either the control register or calibration registers. In either case, the write operation is not affected by the $\overline{DRDY}$ line and the write operation does not have any effect on the status of $\overline{DRDY}$. A write operation to the control register or the calibration register must always write 24 bits to the respective register.

Figure 9a shows a write operation to the part with $\overline{TFS}$ remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. As before, the serial clock line should be low between read and write operations. The serial data to be loaded to the part must be valid on the high level of the externally applied SCLK signal. Data is clocked into the part on the high level of this SCLK signal with the MSB transferred first. On the last active high time of SCLK, the LSB is loaded to the part.

Figure 9b shows a timing diagram for a write operation to the AD7710/AD7712 with $\overline{TFS}$ returning high during the write operation and returning low again to write the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 9a, but Figure 9b has a number of additional times to show timing relationships when $\overline{TFS}$ returns high in the middle of transferring a word.

Data to be loaded to the part must be valid for 5/2 MCLK IN cycles prior to the falling edge of the SCLK signal. $\overline{TFS}$ should return high during the low time of SCLK. After $\overline{TFS}$ returns low again, the next bit of the data word to be loaded to the part is clocked in on next high level of the SCLK input. On the last active high time of the SCLK input, the LSB is loaded to the part.

LC²MOS Signal Conditioning ADCs with RTD Excitation Currents

AD7711/AD7713

FEATURES

Charge Balancing ADC
24 Bits No Missing Codes
±0.0015% Nonlinearity
Programmable Gain Front End
Gains from 1 to 128
Three Input Channels (AD7713)
Two Input Channels (AD7711)
Low-Pass Filter with Programmable Filter Cutoffs
Ability to Read/Write Calibration Coefficients
RTD Excitation Current Sources
Bidirectional Microcontroller Serial Interface
Single Supply Operation
Low Power (AD7711: 25 mW typ; AD7713: 3.5 mW typ)
Power-Down Mode

GENERAL DESCRIPTION

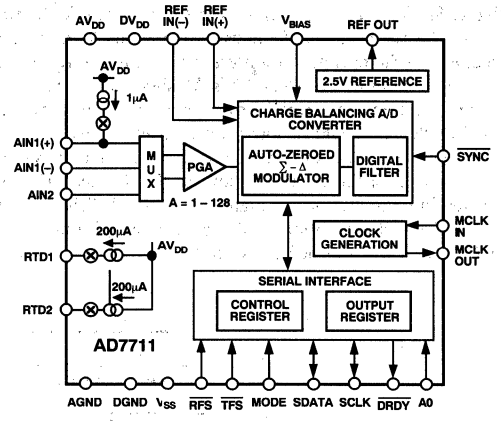
The AD7711/AD7713 is a complete analog front end for low frequency measurement applications. The device accepts low level signals directly from a transducer and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 24 bits of no missing codes performance. The input signal is applied to a proprietary* programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

The AD7711 features one differential analog input and one single-ended analog input. The AD7713 features two differential inputs and one single-ended high level ($4 \times V_{REF}$/Gain) input. Both parts feature a differential reference input and can be operated from a single +5 V supply. The AD7711 can also be operated from dual supplies to allow for negative input voltages. The parts provide two current sources which can be used to provide excitation in three-wire and four-wire RTD configurations.

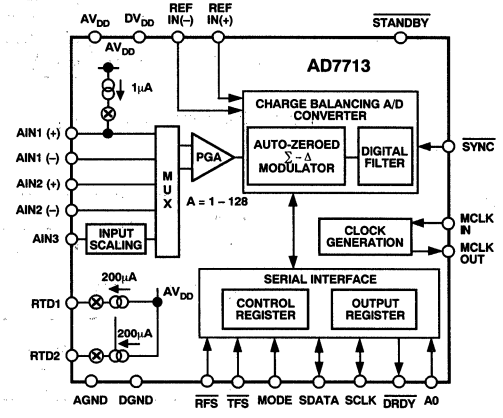
The AD7711/AD7713 is ideal for use in smart, microcontroller-based systems. Gain settings, signal polarity and RTD current control can be configured in software using the bidirectional serial port. The part contains self-calibration, system calibration and background calibration options and also allows the user to read and to write the on-chip calibration registers.

*Protected by U.S. Patent No. 5,134,401.

AD7711 FUNCTIONAL BLOCK DIAGRAM



AD7713 FUNCTIONAL BLOCK DIAGRAM



CMOS construction ensures very low power dissipation and a power-down mode reduces the stand-by power consumption to 7 mW typical (AD7711) and 300 μW typical (AD7713). The part is available in a 24-pin, 0.3 inch wide, plastic and hermetic dual-in-line package (DIP) as well as a 24-lead small outline (SOIC) package.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7713—SPECIFICATIONS

(AV_{DD} = +5 V ± 5%; DV_{DD} = +5 V ± 5%; REF IN(+) = +2.5 V; REF IN(−) = AGND; MCLK IN = 2 MHz, unless otherwise stated. All specifications T_{MIN} to T_{MAX}, unless otherwise noted.)

Parameter	A, S Versions[1]	Units	Conditions/Comments
STATIC PERFORMANCE			
No Missing Codes	24	Bits min	Guaranteed by Design. For Filter Notches ≤ 12 Hz
	22	Bits min	For Filter Notch = 20 Hz
	18	Bits min	For Filter Notch = 50 Hz
	15	Bits min	For Filter Notch = 100 Hz
	12	Bits min	For Filter Notch = 200 Hz
Output Noise	See Tables I & II		Depends on Filter Cutoffs and Selected Gain
Integral Nonlinearity			
@ 25°C	±0.0045	% of FSR max	Filter Notches ≤ 12 Hz; Typically ±0.0015%
T_{MIN} to T_{MAX}	±0.0075	% of FSR max	Filter Notches ≤ 12 Hz
Positive Full-Scale Error[2, 3]	See Note 4		
Full-Scale Drift[5]	3/GAIN	µV/°C typ	For Gains of 1, 2, 4, 8

Gain Drift	1	ppm/°C typ	Additional Drift Contributed by Resistor Attenuator
Offset Error[11]	8	mV max	Additional Error Contributed by Resistor Attenuator

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version, −55°C to +125°C. See also Note 16.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors.

[6]These numbers are guaranteed by design and/or characterization.

[7]The AIN1 and AIN2 analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance depends on the selected gain.

[8]The analog input voltage range on the AIN1(+) and AIN2(+) inputs is given here with respect to the voltage on the AIN1(−) and AIN2(−) inputs. The input voltage range on the AIN3 input is with respect to AGND. The absolute voltage on the AIN1 and AIN2 inputs should not go more positive than AV_{DD} + 30 mV or more negative than AGND − 30 mV.

[9]V_{REF} = REF IN(+) − REF IN(−).

[10]This common-mode voltage range is allowed provided that the input voltage on AIN(+) and AIN(−) does not exceed AV_{DD} + 30 mV and AGND − 30 mV.

[11]This error can be removed using the system calibration capabilities of the AD7711/AD7713. This error is not removed by the AD7711/AD7713's self-calibration feature. The offset drift on the AIN3 input is four times the value given in the Static Performance section.

Offset Calibration Limit[15]	0 to V_{REF}/GAIN	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Input Span	+3.2 × V_{REF}/GAIN	V min	GAIN Is the Selected PGA Gain (Between 1 and 128)
	+(4.2 × V_{REF})/GAIN	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)

NOTES

[12]Sample tested at +25°C to ensure compliance.

[13]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[14]These calibration and span limits apply provided the absolute voltage on the AIN1 and AIN2 analog inputs does not exceed AV_{DD} + 30 mV or go more negative than AGND – 30 mV.

[15]The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

Parameter	A, S Versions[1]	Units	Conditions/Comments
POWER REQUIREMENTS			
Power Supply Voltages			
AV_{DD} Voltage[16]	+5 to +10	V nom	±5% for Specified Performance
DV_{DD} Voltage[17]	+5	V nom	±5% for Specified Performance
Power Supply Currents			
AV_{DD} Current	0.6	mA max	AV_{DD} = +5 V
AV_{DD} Current	0.7	mA max	AV_{DD} = +10 V
DV_{DD} Current	0.5	mA max	$f_{CLK\ IN}$ = 1 MHz. Digital Inputs 0 V or DV_{DD}
DV_{DD} Current	1	mA max	$f_{CLK\ IN}$ = 2 MHz. Digital Inputs 0 V or DV_{DD}
Power Supply Rejection[18] (AV_{DD})	See Note 19	dB typ	Rejection w.r.t. AGND
Power Dissipation			
Normal Mode	5.5	mW max	AV_{DD} = DV_{DD} = +5 V, $f_{CLK\ IN}$ = 1 MHz; Typically 3.5 mW
Standby (Power-Down) Mode	500	μW max	AV_{DD} = DV_{DD} = +5 V; Typically 300 μW

NOTES
[16]Operation with AV_{DD} voltages in the range 5.25 V to 10.5 V is only guaranteed over the 0°C to +70°C temperature range.
[17]The ±5% tolerance on the DV_{DD} input is allowed provided that DV_{DD} does not exceed AV_{DD} by more than 0.3 V.
[18]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 2, 5, 10, 25 or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 2, 6, 10, 30 or 60 Hz.
[19]PSRR depends on gain: Gain of 1 = 70 dB typ; Gain of 2 = 75 dB typ; Gain of 4 = 80 dB typ; Gains of 8 to 128 = 85 dB typ.
Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of the specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V, which readily accumulate on the human body and on test equipment, can discharge without detection. Although devices feature proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper precautions are recommended to avoid any performance degradation or loss of functionality.

AD7713 ORDERING GUIDE

AD7711—SPECIFICATIONS

(AV_{DD} = +5 V ± 5%; DV_{DD} = +5 V ± 5%; V_{SS} = 0 V or −5 V ± 5%; REF IN(+) = +2.5 V; REF IN(−) = AGND; MCLK IN = 10 MHz unless otherwise stated. All specifications T_{MIN} to T_{MAX}, unless otherwise noted.)

Parameter	A, S Versions[1]	Units	Conditions/Comments
STATIC PERFORMANCE			
No Missing Codes	24	Bits min	Guaranteed by Design. For Filter Notches ≤ 60 Hz
	22	Bits min	For Filter Notch = 100 Hz
	18	Bits min	For Filter Notch = 250 Hz
	15	Bits min	For Filter Notch = 500 Hz
	12	Bits min	For Filter Notch = 1 kHz
Output Noise	See Tables I & II		Depends on Filter Cutoffs and Selected Gain
Integral Nonlinearity			
@ 25°C	±0.0045	% of FSR max	Filter Notches ≤ 60 Hz. Typically ±0.0015%
T_{MIN} to T_{MAX}	±0.0075	% of FSR max	Filter Notches ≤ 60 Hz
Positive Full-Scale Error[2, 3]	See Note 4		Excluding Reference
Full-Scale Drift[5]	3/GAIN	μV/°C typ	Excluding Reference. For Gains of 1, 2, 4, 8
	0.35	μV/°C typ	Excluding Reference. For Gains of 16, 32, 64, 128
Unipolar Offset Error[2]	See Note 4		
Unipolar Offset Drift[5]	2.5/GAIN	μV/°C typ	For Gains of 1, 2, 4, 8
	0.3	μV/°C typ	For Gains of 16, 32, 64, 128
Bipolar Zero Error[2]	See Note 4		
Bipolar Zero Drift[5]	2.5/GAIN	μV/°C typ	For Gains of 1, 2, 4, 8
	0.3	μV/°C typ	For Gains of 16, 32, 64, 128
Bipolar Negative Full-Scale Error[2]	±0.006	% of FSR max	Excluding Reference. Typically ±0.0015%
Bipolar Negative Full-Scale Drift[5]	4/GAIN	μV/°C typ	Excluding Reference. For Gains of 1, 2, 4, 8
	0.5	μV/°C typ	Excluding Reference. For Gains of 16, 32, 64, 128
ANALOG INPUTS/REFERENCE INPUTS			
Normal Mode 50 Hz Rejection[6]	100	dB min	For Filter Notches of 10, 25, 50 Hz, ±0.02 × f_{NOTCH}
Normal Mode 60 Hz Rejection[6]	100	dB min	For Filter Notches of 10, 30, 60 Hz, ±0.02 × f_{NOTCH}
DC Input Leakage Current[6] @ +25°C	10	pA max	
T_{MIN} to T_{MAX}	1	nA max	
Sampling Capacitance[6]	20	pF max	
AIN1/REF IN			
Common-Mode Rejection (CMR)	92	dB min	At DC
Common-Mode 50 Hz Rejection[6]	150	dB min	For Filter Notches of 10, 25, 50 Hz, ±0.02 × f_{NOTCH}
Common-Mode 60 Hz Rejection[6]	150	dB min	For Filter Notches of 10, 30, 60 Hz, ±0.02 × f_{NOTCH}
Common-Mode Voltage Range[7]	V_{SS} to AV_{DD}	V min to V max	
Analog Inputs[8]			
Input Voltage Range[9]			For Normal Operation. Depends on Gain Selected.
	0 to $+V_{REF}$[10]	max	Unipolar Input Range (B/U Bit of Control Register = 1)
	$\pm V_{REF}$	max	Bipolar Input Range (B/U Bit of Control Register = 0)
Input Sampling Rate, f_S	See Table III		
AIN2 Offset Error	4	mV max	Removed by System Calibrations but not by Self-Calibration
AIN2 Offset Drift	2	μV/°C	Removed by System Calibration but not by Self-Calibration
Reference Inputs			
REF IN(+) − REF IN(−) Voltage[11]	+2.5 to +5	V min to V max	For Specified Performance; Part Is Functional with Lower V_{REF} Voltages
Input Sampling Rate, f_S	$f_{CLK\ IN}$/512		
REFERENCE OUTPUT			
Output Voltage	2.5	V nom	
Initial Tolerance	±4	% max	
Drift	25	ppm/°C typ	
Output Noise	50	μV typ	pk–pk Noise. 0.1 Hz to 10 Hz Bandwidth
Line Regulation (AV_{DD})	1	mV/V max	
Load Regulation	1.5	mV/mA max	Maximum Load Current 1 mA
External Current	1	mA max	

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version, −55°C to +125°C. See also Note 16.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors.

[6]These numbers are guaranteed by design and/or characterization.

[7]This common-mode voltage range is allowed, provided that the input voltage on AIN(+) or AIN(−) does not exceed AV_{DD} + 30 mV and V_{SS} − 30 mV.

[8]The analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance depends on the selected gain (see Tables IV and V).

[9]The analog input voltage range on the AIN1(+) input is given here with respect to the voltage on the AIN1(−) input. The input voltage range on the AIN2 input is with respect to AGND. The absolute voltage on the analog inputs should not go more positive than AV_{DD} + 30 mV or go more negative than V_{SS} − 30 mV.

[10]V_{REF} = REF IN(+) − REF IN(−).

[11]The reference voltage range may be restricted by the input voltage range requirement on the V_{BIAS} input.

Parameter	A, S Versions[1]	Units	Conditions/Comments
V_{BIAS} INPUT[12]			
Input Voltage Range	$AV_{DD} - 0.85 \times V_{REF}$		See V_{BIAS} Input Section
	or $AV_{DD} - 3$	V max	Whichever Is Smaller; +5 V/−5 V or +10 V/0 V Nominal AV_{DD}/V_{SS}
	or $AV_{DD} - 2.1$	V max	Whichever Is Smaller; +5 V/0 V Nominal AV_{DD}/V_{SS}
	$V_{SS} + 0.85 \times V_{REF}$		See V_{BIAS} Input Section
	or $V_{SS} + 3$	V min	Whichever Is Greater; +5 V/−5 V or +10 V/0 V Nominal AV_{DD}/V_{SS}
	or $V_{SS} + 2.1$	V min	Whichever Is Greater; +5 V/0 V Nominal AV_{DD}/V_{SS}
V_{BIAS} Rejection	65 to 85	dB typ	Increasing with Gain
LOGIC INPUTS			
Input Current	±10	μA max	
All Inputs except MCLK IN			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	2.0	V min	
MCLK IN Only			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	3.5	V min	
LOGIC OUTPUTS			
V_{OL}, Output Low Voltage	0.4	V max	I_{SINK} = 1.6 mA
V_{OH}, Output High Voltage	4.0	V min	I_{SOURCE} = 100 μA
Floating State Leakage Current	±10	μA max	
Floating State Output Capacitance[13]	9	pF typ	
TRANSDUCER BURN-OUT			
Current	100	nA nom	
Initial Tolerance	±10	% typ	
Drift	0.1	%/°C typ	
RTD EXCITATION CURRENTS (RTD1, RTD2)			
Output Current	200	μA nom	
Initial Tolerance	±20	% max	
Drift	20	ppm/°C typ	
Initial Matching	±1	% max	Matching Between RTD1 and RTD2 Currents
Drift Matching	3	ppm/°C typ	Matching Between RTD1 and RTD2 Current Drift
Line Regulation (AV_{DD})	200	nA/V max	AV_{DD} = +5 V
Load Regulation	200	nA/V max	
Output Compliance	$AV_{DD} - 2$	V max	
SYSTEM CALIBRATION			
Positive Full-Scale Calibration Limit[14]	$(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Negative Full-Scale Calibration Limit[14]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Offset Calibration Limit[15]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Input Span[15]	$0.8 \times V_{REF}/GAIN$	V min	GAIN Is the Selected PGA Gain (Between 1 and 128)
	$(2.1 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)

NOTES

[12]The AD7711 is tested with the following V_{BIAS} voltages. With AV_{DD} = +5 V and V_{SS} = 0 V, V_{BIAS} = +2.5 V; with AV_{DD} = +10 V and V_{SS} = 0 V, V_{BIAS} = +5 V and with AV_{DD} = +5 V and V_{SS} = −5 V, V_{BIAS} = 0 V.

[13]Sample tested at +25°C to ensure compliance.

[14]After calibration, if the analog input exceeds positive full scale, then the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[15]These calibration and span limits apply provided that the absolute voltage on the analog inputs does not exceed AV_{DD} + 30 mV or does not go more negative than V_{SS} − 30 mV. The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

AD7711—SPECIFICATIONS

Parameter	A, S Versions[1]	Units	Conditions/Comments
POWER REQUIREMENTS			
Power Supply Voltages			
AV_{DD} Voltage[16]	+5 to +10	V nom	±5% for Specified Performance
DV_{DD} Voltage[17]	+5	V nom	±5% for Specified Performance
AV_{DD} – V_{SS} Voltage	+10.5	V max	For Specified Performance
Power Supply Currents			
AV_{DD} Current	4	mA max	
DV_{DD} Current	4.5	mA max	
V_{SS} Current	1.5	mA max	V_{SS} = −5 V
Power Supply Rejection[18]			Rejection w.r.t. AGND; Assumes V_{BIAS} Is Fixed
Positive Supply (AV_{DD})	See Note 19	dB typ	
Negative Supply (V_{SS})	90	dB typ	
Power Dissipation			
Normal Mode	45	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V; Typically 25 mW
Normal Mode	52.5	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = −5 V; Typically 30 mW
Standby (Power-Down) Mode	15	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V or −5 V; Typically 7 mW

[16]The AD7711 is specified with a 10 MHz clock for AV_{DD} voltages of +5 V ± 5%. It is specified with an 8 MHz clock for AV_{DD} voltages greater than 5.25 V and less than 10.5 V. Operating with AV_{DD} voltages in the range 5.25 V to 10.5 V is only guaranteed over the 0°C to +70°C temperature range.
[17]The ±5% tolerance on the DV_{DD} input is allowed provided that DV_{DD} does not exceed AV_{DD} by more than 0.3 V.
[18]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 10 Hz, 25 Hz or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 10 Hz, 30 Hz or 60 Hz.
[19]PSRR depends on gain: Gain of 1 = 70 dB typ; Gain of 2 = 75 dB typ; Gain of 4 = 80 dB typ; Gains of 8 to 128 = 85 dB typ. These numbers can be improved (to 95 dB typ) by deriving the V_{BIAS} voltage (via Zener diode or reference) from the AV_{DD} supply.

Specifications subject to change without notice.

Vapor Phase (60 sec) . . . . . +215°C
Infrared (15 sec) . . . . . +220°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7711 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

AD7711 ORDERING GUIDE

Model	Temperature Range	Package Option*
AD7711AN	−40°C to +85°C	N-24
AD7711AR	−40°C to +85°C	R-24
AD7711AQ	−40°C to +85°C	Q-24
AD7711SQ	−55°C to +125°C	Q-24

*N = Plastic DIP; Q = Cerdip; R = SOIC. For outline information see Package Information section.

TIMING CHARACTERISTICS[1, 2] (DV_{DD} = +5 V ± 5%; AV_{DD} = +5 V or +10 V[3] ± 5%; AGND = DGND = 0 V; $f_{CLK\ IN}$ = 10 MHz (AD7711) or 2 MHz (AD7713); Input Logic 0 = 0 V, Logic 1 = DV_{DD} unless otherwise stated.)

Parameter	Limit at T_{MIN}, T_{MAX} (A, S Versions)	Units	Conditions/Comments
$f_{CLK\ IN}$[4, 5]	400	kHz min	Master Clock Frequency
	2	MHz max	AD7713
	10	MHz max	AD7711
$t_{CLK\ IN\ LO}$	0.4 × $t_{CLK\ IN}$	ns min	Master Clock Input Low Time; $t_{CLK\ IN}$ = 1/$f_{CLK\ IN}$
$t_{CLK\ IN\ HI}$	0.4 × $t_{CLK\ IN}$	ns min	Master Clock Input High Time
t_r[6]	50	ns max	Digital Output Rise Time; Typically 20 ns

t_{32}	0	ns min	A0 to $\overline{TFS}$ Setup Time
t_{33}	0	ns min	A0 to $\overline{TFS}$ Hold Time
t_{34}	$4 \times t_{CLK\ IN}$	ns min	SCLK Falling Edge to $\overline{TFS}$ Hold Time
t_{35}	$5 \times t_{CLK\ IN}/2 - $ SCLK High	ns min	Data Valid to SCLK Setup Time
t_{36}	30	ns min	Data Valid to SCLK Hold Time

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with $t_R = t_F = 5$ ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]See Figures 6 to 9 of AD7710/AD7712 data sheet.

[3]Operation with AV_{DD} voltages in the range 5.25 V to 10.5 V is only guaranteed over the 0°C to +70°C temperature range.

[4]CLK IN duty cycle range is 45% to 55%. CLK IN must be supplied whenever the AD7711/AD7713 is not in STANDBY mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[5]The AD7711 is production tested at 10 MHz. The AD7713 is production tested with $f_{CLK\ IN}$ at 2 MHz. Both are guaranteed by characterization to operate at 400 kHz.

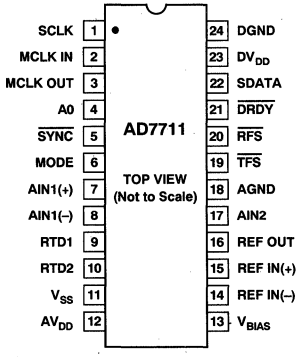
[6]Specified using 10% and 90% points on waveform of interest.

[7]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross 0.8 V or 2.4 V.

[8]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 100 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.

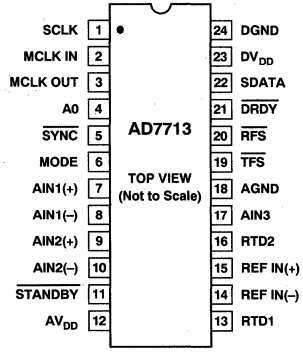
AD7711 PIN CONFIGURATION

DIP and SOIC



AD7713 PIN CONFIGURATION

DIP and SOIC



PIN FUNCTION DESCRIPTION

Mnemonic	Function
SCLK	Serial Clock. Logic input/output depending on the status of the MODE pin. When MODE is high, the device is in its self-clocking mode and the SCLK pin provides a serial clock output. This SCLK becomes active when $\overline{RFS}$ or $\overline{TFS}$ goes low and it goes high impedance when either $\overline{RFS}$ or $\overline{TFS}$ returns high or when the device has completed transmission of an output word. When MODE is low, the device is in its external clocking mode and the SCLK pin acts as an input. This input serial clock can be a continuous clock with all data transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7711/AD7713 in smaller batches of data.
MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS-compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally 2 MHz for AD7713 and 10 MHz for AD7711.
MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT.
A0	Address Input. With this input low, reading and writing to the device is to the control register. With this input high, access is to either the data register or the calibration registers.
$\overline{SYNC}$	Logic Input which allows for synchronization of the digital filters when using a number of AD7711/AD7713s. It resets the nodes of the digital filter.
MODE	Logic Input. When this pin is high, the device is in its self-clocking mode; with this pin low, the device is in its external clocking mode.
AIN1(+)	Analog Input Channel 1. Positive input of the programmable-gain differential analog input. The AIN1(+) input is connected to an output current source which can be used to check that an external transducer has burnt out or has gone open circuit. This output current source can be turned on/off via the control register.
AIN1(−)	Analog Input Channel 1. Negative input of the programmable gain differential analog input.
AIN2	AD7711 Only. Analog Input Channel 2. Single-ended programmable gain analog input.
REF OUT	AD7711 Only. Reference Output. The internal +2.5 V reference is provided at this pin. This is a single-ended output which is reference to AGND. It is a buffered output capable of providing 1 mA to an external load.
V_{BIAS}	AD7711 Only. Input Bias Voltage. This input voltage should be set such that $V_{BIAS} + 0.85 \times V_{REF} < AV_{DD}$ and $V_{BIAS} - 0.85 \times V_{REF} > V_{SS}$ where V_{REF} is REF IN(+) − REF IN(−). See V_{BIAS} input section.
V_{SS}	AD7711 Only. Analog Negative Supply, 0 V to −5 V. Tied to AGND for single supply operation. The input voltage on AIN1 or AIN2 should not go >30 mV negative w.r.t. V_{SS} for correct operation of the device.
AIN2(+)	AD7713 Only. Analog Input Channel 2. Positive input of the programmable gain differential analog input.
AIN2(−)	AD7713 Only. Analog Input Channel 2. Negative input of the programmable gain differential analog input.
$\overline{STANDBY}$	AD7713 Only. Logic Input. Taking this pin low shuts down the internal analog and digital circuitry, reducing power consumption to less than 50 μW.
AV_{DD}	Analog Positive Supply Voltage, +5 V to +10 V.
RTD1	Constant Current Output. A nominal 200 μA constant current is provided at this pin and this can be used as the excitation current for RTDs. This, current can be turned on or off via the control register.
RTD2	Constant Current Output. A nominal 200 μA constant current is provided at this pin and this can be used as the excitation current for RTDs. This current can be turned on or off via the control register. This second current can be used to eliminate lead resistance errors in three-wire RTD configurations.
REF IN(−)	Reference Input. The REF IN(−) can lie anywhere between AV_{DD} and AGND provided REF IN(+) is greater than REF IN(−).
REF IN(+)	Reference Input. The reference input is differential with the provision that REF IN(+) must be greater than REF IN(−). REF IN(+) can lie anywhere between AV_{DD} and AGND.
AIN3	AD7713 only. Analog Input Channel 3. High level analog input which accepts an analog input voltage range of $4 \times V_{REF}$/GAIN. At the nominal V_{REF} of +2.5 V and a gain of 1, the AIN3 input voltage range is 0 to +10 V.
AGND	Ground Reference Point for Analog Circuitry.
$\overline{TFS}$	Transmit Frame Synchronization. Active low logic input used to write serial data to the device with serial data expected after the falling edge of this pulse. In the self-clocking mode, the serial clock becomes active after $\overline{TFS}$ goes low. In the external clocking mode, $\overline{TFS}$ must go low before the first bit of the data word is written to the part.
$\overline{RFS}$	Receive Frame Synchronization. Active low logic input used to access serial data from the device. In the self-clocking mode, the SCLK and SDATA lines both become active after $\overline{RFS}$ goes low. In the external clocking mode, the SDATA line becomes active after $\overline{RFS}$ goes low.

Mnemonic	Function
$\overline{DRDY}$	Logic Output. A falling edge indicates a new output word is available for transmission. The $\overline{DRDY}$ pin will return high upon completion of transmission of a full output word. $\overline{DRDY}$ is also used to indicate when the AD7711/AD7713 has completed its on-chip calibration sequence.
SDATA	Serial Data. Input/Output with serial data being written to either the control register or the calibration registers and serial data being accessed from the control register, calibration registers or the data register. During an output data read operation, serial data becomes active after $\overline{RFS}$ goes low (provided $\overline{DRDY}$ is low). During a write operation, valid serial data is expected on the rising edges of SCLK when $\overline{TFS}$ is low. The output data is natural binary for unipolar inputs and offset binary for bipolar inputs.
DV_{DD}	Digital Supply Voltage, +5 V. DV_{DD} should never exceed AV_{DD} by more than 0.3 V. If DV_{DD} powers up before AV_{DD} or if DV_{DD} can exceed AV_{DD} by more than 0.3 V at any other time, the protection scheme outlined in Figure 5 should be used.
DGND	Ground Reference Point for Digital Circuitry.

TERMINOLOGY

INTEGRAL NONLINEARITY

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

POSITIVE FULL-SCALE ERROR

Positive full-scale error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal input full-scale voltage. For AIN(+), the ideal full-scale input voltage is (AIN(−) + V_{REF}/GAIN − 3/2 LSBs); for AIN2 of AD7711, the ideal full-scale input voltage is V_{REF}/GAIN − 3/2 LSBs; for AIN3 of AD7713, the ideal full-scale voltage is +4 × V_{REF}/GAIN − 3/2 LSBs. Positive full-scale error applies to both unipolar and bipolar analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar offset error is the deviation of the first code transition from the ideal input voltage. For AIN(+), the ideal input voltage is (AIN(−) + 0.5 LSB); for AIN2 of AD7711 and AIN3 of AD7713, the ideal input is 0.5 LSB when operating in the Unipolar Mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal input voltage. For AIN(+), the ideal input voltage is (AIN(−) − 0.5 LSB); for AIN2 of AD7711 the ideal input is −0.5 LSB; AIN3 of AD7713 can only accommodate unipolar input ranges.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal input voltage. For AIN(+), the ideal input voltage is (AIN(−) −V_{REF}/GAIN + 0.5 LSB); for AIN2 of AD7711 the ideal input is −V_{REF}/GAIN to 0.5 LSB when operating from dual supplies; AIN3 of AD7713 can only accommodate unipolar input ranges.

POSITIVE FULL-SCALE OVERRANGE

Positive full-scale overrange is the amount of overhead available to handle input voltages on the AIN(+) inputs greater than (AIN(−) + V_{REF}/GAIN) or on AIN2 of AD7711 of greater than V_{REF}/GAIN or AIN3 of AD7713 of greater than +4 × V_{REF}/GAIN (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or to overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages on AIN(+) below (AIN(−) − V_{REF}/GAIN) or on AIN2 of AD7711 below −V_{REF}/GAIN without overloading the analog modulator or overflowing the digital filter.

OFFSET CALIBRATION RANGE

In the system calibration modes, the AD7711/AD7713 calibrates its offset with respect to the analog input. The offset calibration range specification defines the range of voltages that the AD7711/AD7713 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7711/AD7713 can accept in the system calibration mode and still calibrate full scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7711/AD7713's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full scale that the AD7711/AD7713 can accept and still calibrate gain accurately.

Control Register (24 Bits)

A write to the device with the A0 input low writes data to the control register. A read to the device with the A0 input low accesses the contents of the control register. The control register is 24-bits wide and when writing to the register 24 bits of data must be written otherwise the data will not be loaded to the control register. In other words, it is not possible to write just the first 12 bits of data into the control register. If more than 24 clock pulses are provided before $\overline{TFS}$ returns high, then all clock pulses after the 24th clock pulse are ignored. Similarly, a read operation from the control register should access 24 bits of data.

MSB

MD2	MD1	MD0	G2	G1	G0	S1[1]	S2[2]	WL	RO	BO	B/U
FS11	FS10	FS9	FS8	FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0

LSB

NOTES
[1]On the AD7711 this bit is CH, and on the AD7713 this bit is CH1.
[2]On the AD7711 this bit is PD, and on the AD7713 this bit is CH0.

Operating Mode

MD2	MD1	MD0	Operating Mode
0	0	0	Normal Mode. This is the normal mode of operation of the device whereby a read to the device with A0 high accesses data from the data register. This is the default condition of these bits after the internal power-on reset.
0	0	1	Activate Self-Calibration. This activates self-calibration on the channel selected by CH (CH0 and CH1 on AD7713). This is a one-step calibration sequence, and when complete, the part returns to Normal Mode (with MD2, MD1, MD0 of the control register returning to 0, 0, 0). The $\overline{DRDY}$ line indicated when this self-calibration is complete and valid data is available in the output register. For this calibration type, the zero-scale calibration is done internally on shorted (zeroed) inputs and the full-scale calibration is done internally on V_{REF}.
0	1	0	Activate System Calibration. This activates system calibration on the channel selected by CH (CH0 and CH1 on AD7713). This is a two-step calibration sequence, with the zero-scale calibration done first on the selected input channel and $\overline{DRDY}$ indicating when this zero-scale calibration is complete. The part returns to Normal Mode at the end of this first step in the two-step sequence.
0	1	1	Activate System Calibration. This is the second step of the system calibration sequence with full-scale calibration being performed on the selected input channel. Once again, $\overline{DRDY}$ indicated when this full-scale calibration is complete. When this calibration is complete, the part returns to Normal Mode.
1	0	0	Activate System-Offset Calibration. This activates system-offset calibration on the channel selected by CH (CH0 and CH1 on AD7713). This is a one step calibration sequence and when complete the part returns to Normal Mode with $\overline{DRDY}$ indicating when this system offset calibration is complete. For this calibration type, the zero-scale calibration is done on the selected input channel and the full-scale calibration is done internally on V_{REF}.
1	0	1	Activate Background Calibration. This activates background calibration on the channel selected by CH (CH0 and CH1 on AD7713). If the background calibration mode is on, then the AD7711/AD7713 provides continuous self-calibration of the reference and shorted (zeroed) inputs. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the device when there is a change in the ambient temperature. In this mode, shorted (zeroed) inputs and V_{REF}, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are updated.
1	1	0	Read/Write Zero-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the zero-scale calibration coefficients of the channel selected by CH (CH0 and CH1 on AD7713). A write to the device with A0 high writes data to the zero-scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register. Therefore, when writing to the calibration register, 24 bits of data must be written, otherwise the new data will not be transferred to the calibration register.
1	1	1	Read/Write Full-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the full-scale calibration coefficients of the channel selected by CH (CH0 and CH1 on AD7713). A write to the device with A0 high writes data to the full-scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register. Therefore, when writing to the calibration register, 24 bits of data must be written, otherwise, the new data will not be transferred to the calibration register.

Filter Selection (FS11–FS0)

The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$) filter response. The 12 bits of data programmed into these bits determine the filter cutoff frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device.

The first notch of the filter occurs at a frequency determined by the relationship: filter first notch frequency = $(f_{CLK\ IN}/512)/code$ where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 2,000. The value of the code loaded to these bits **must** be within this range. Failure to do this will result in unspecified operation of the device.

Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I and II show the effect of the filter notch frequency and gain on the effective resolution of the part. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is at 10 Hz then a new word is available at a 10 Hz rate or every 100 ms. If the first notch is at 200 Hz, a new word is available every 5 ms.

The settling time of the filter to a full-scale step input change is worst case 4 × 1/(the output data rate). This settling time is to 100% of the final value. For example, with the first filter notch at 10 Hz, the settling time of the filter to a full-scale step input change is 400 ms max. This settling time can be reduced to 3 × 1/(output data rate) by synchronizing the step input change to a reset of the digital filter. In other words, if the step input takes place with $\overline{SYNC}$ low, the settling time will be 3 × 1/(output data rate). If a change of channel takes place, the settling time is 3 × 1/(output data rate) regardless of the $\overline{SYNC}$ input, but $\overline{DRDY}$ does not stay high for 3 × 1/output rate. The −3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter −3 dB frequency = 0.262 × first notch frequency.

Tables I and II show the output rms noise for some typical notch and −3 dB frequencies for the AD7711. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. These numbers are typical and are generated with an analog input voltage of 0 V. The output noise from the part comes from two sources. The first is the electrical noise in the semiconductor devices used in the implementation of the modulator (device noise). The second occurs when the analog input signal is converted into the digital domain adding quantization noise. The device noise is at a low level and is largely independent of frequency. The quantization noise starts at an even lower level but rises rapidly with increasing frequency to become the dominant noise source. Consequently, lower filter notch settings (below 60 Hz approximately) tend to be device noise dominated while higher notch settings are dominated by quantization noise. Changing the filter notch and cutoff frequency in the quantization noise dominated region results in a more dramatic improvement in noise performance than it does in the device noise dominated region as shown in Table I. Furthermore, quantization noise is added after the PGA, so effective resolution is independent of gain for the higher filter notch frequencies. Meanwhile, device noise is added in the PGA and, therefore, effective resolution suffers a little at high gains for lower notch frequencies.

At the lower filter notch settings (below 60 Hz), the no missing codes performance of the device is at the 24-bit level. At the higher settings, more codes will be missed until at 1 kHz notch setting, no missing codes performance is only guaranteed to the 12-bit level. However, since the effective resolution of the part is 10.5 bits for this filter notch setting, this no missing codes performance should be more than adequate for all applications.

The effective resolution of the device is defined as the ratio of the output rms noise to the input full scale. This does not remain constant with increasing gain or with increasing bandwidth. Table II shows the same table as Table I except that the output is now expressed in terms of effective resolution (the magnitude of the rms noise with respect to 2 × V_{REF}/GAIN, i.e., the input full scale). It is possible to do post filtering on the device to improve the output data rate for a given −3 dB frequency and also to further reduce the output noise (see Digital Filtering section).

Table I. Output Noise vs. Gain and First Notch Frequency for AD7711

First Notch of Filter and O/P Data Rate[1]	−3 dB Frequency	Typical Output RMS Noise (μV)							
		Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz[2]	2.62 Hz	1.7	1.0	0.5	0.36	0.36	0.36	0.36	0.36
25 Hz[2]	6.55 Hz	4.9	2.2	1.2	0.6	0.36	0.36	0.36	0.36
30 Hz[2]	7.86 Hz	6.1	2.4	1.2	0.84	0.5	0.36	0.36	0.36
50 Hz[2]	13.1 Hz	7.5	3.8	2.0	1.0	0.6	0.5	0.5	0.45
60 Hz[2]	15.72 Hz	8.5	4.0	2.0	1.0	0.6	0.5	0.5	0.45
100 Hz[3]	26.2 Hz	13	6.4	3.7	1.8	1.1	0.9	0.65	0.65
250 Hz[3]	65.5 Hz	130	75	25	12	7.5	4	2.7	1.7
500 Hz[3]	131 Hz	0.6×10^3	0.26×10^3	140	70	35	25	15	8
1 kHz[3]	262 Hz	3.1×10^3	1.6×10^3	0.7×10^3	0.29×10^3	180	120	70	40

NOTES
[1]The default condition (after the internal power-on reset) for the first notch of filter is 60 Hz.
[2]For these filter notch frequencies, the output rms noise is primarily dominated by device noise and as a result is independent of the value of the reference voltage. Therefore, increasing the reference voltage will give an increase in the effective resolution of the device (i.e., the ratio of the rms noise to the input full scale is increased since the output rms noise remains constant as the input full scale increases).
[3]For these filter notch frequencies, the output rms noise is dominated by quantization noise and as a result is proportional to the value of the reference voltage.

Table II. Effective Resolution vs. Gain and First Notch Frequency for AD7711

First Notch of Filter and O/P Data Rate	−3 dB Frequency	Effective Resolution[1] (Bits)							
		Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz	2.62 Hz	21.5	21.5	21.5	20.5	19.5	18.5	17.5	16.5
25 Hz	6.55 Hz	20	20	20	20	19.5	18.5	17.5	16.5
30 Hz	7.86 Hz	19.5	20	20	19.5	19.5	18.5	17.5	16.5
50 Hz	13.1 Hz	19.5	19.5	19.5	19.5	19	18.5	17.5	16.5
60 Hz	15.72 Hz	19	19.5	19.5	19.5	19	18.5	17.5	16.5
100 Hz	26.2 Hz	18.5	18.5	18.5	18.5	18	17.5	17	16
250 Hz	65.5 Hz	15	15	15.5	15.5	15.5	15.5	15	14.5
500 Hz	131 Hz	13	13	13	13	13	12.5	12.5	12.5
1 kHz	262 Hz	10.5	10.5	11	11	11	10.5	10	10

NOTE
[1]Effective resolution is defined as the magnitude of the output rms noise with respect to the input full scale (i.e., 2 × V_{REF}/GAIN). The above table applies for a V_{REF} of +2.5 V and resolution numbers are rounded to the nearest 0.5 LSB.

Tables Ia and IIa show the output rms noise for some typical notch and −3 dB frequencies for the AD7713. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. These numbers are typical and are generated with an analog input voltage of 0 V. The output noise from the part comes from two sources. Firstly, there is the electrical noise in the semiconductor devices used in the implementation of the modulator (device noise). Secondly, when the analog input signal is converted into the digital domain, quantization noise is added. The device noise is at a low level and is largely independent of frequency. The quantization noise starts at an even lower level but rises rapidly with increasing frequency to become the dominant noise source. Consequently, lower filter notch settings (below 12 Hz approximately) tend to be device noise dominated while higher notch settings are dominated by quantization noise. Changing the filter notch and cutoff frequency in the quantization-noise dominated region results in a more dramatic improvement in noise performance than it does in the device-noise dominated region as shown in Table Ia. Furthermore, quantization noise is added after the PGA, so effective resolution is independent of gain for the higher filter notch frequencies. Meanwhile, device noise is added in the PGA and, therefore, effective resolution suffers a little at high gains for lower notch frequencies.

At the lower filter notch settings (below 12 Hz), the no missing codes performance of the device is at the 24-bit level. At the higher settings, more codes will be missed until at 200 Hz notch setting, no missing codes performance is only guaranteed to the 12-bit level. However, since the effective resolution of the part is 10.5 bits for this filter notch setting, this no missing codes performance should be more than adequate for all applications.

The effective resolution of the device is defined as the ratio of the output rms noise to the input full scale. This does not remain constant with increasing gain or with increasing bandwidth. Table IIa shows the same table as Table Ia except that the output is now expressed in terms of effective resolution (the magnitude of the rms noise with respect to 2 × V_{REF}/GAIN, i.e., the input full scale). It is possible to do post filtering on the device to improve the output data rate for a given −3 dB frequency and also to further reduce the output noise (see Digital Filtering section).

Table Ia. Output Noise vs. Gain and First Notch Frequency for AD7713

First Notch of Filter and O/P Data Rate[1]	−3 dB Frequency	Typical Output RMS Noise (μV)							
		Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
2 Hz[2]	0.52 Hz	1.7	1.0	0.5	0.36	0.36	0.36	0.36	0.36
5 Hz[2]	1.31 Hz	4.9	2.2	1.2	0.6	0.36	0.36	0.36	0.36
6 Hz[2]	1.57 Hz	6.1	2.4	1.2	0.84	0.5	0.36	0.36	0.36
10 Hz[2]	2.62 Hz	7.5	3.8	2.0	1.0	0.6	0.5	0.5	0.45
12 Hz[2]	3.14 Hz	8.5	4.0	2.0	1.0	0.6	0.5	0.5	0.45
20 Hz[3]	5.24 Hz	13	6.4	3.7	1.8	1.1	0.9	0.65	0.65
50 Hz[3]	13.1 Hz	130	75	25	12	7.5	4	2.7	1.7
100 Hz[3]	26.2 Hz	0.6×10^3	0.26×10^3	140	70	35	25	15	8
200 Hz[3]	52.4 Hz	3.1×10^3	1.6×10^3	0.7×10^3	0.29×10^3	180	120	70	40

NOTES
[1]The default condition (after the internal power-on reset) for the first notch of filter is 12 Hz.
[2]For these filter notch frequencies, the output rms noise is primarily dominated by device noise and a result is independently of the value of the reference voltage. Therefore, increasing the reference voltage will give an increase in the effective resolution of the device (i.e., the ratio of the rms noise to the input full scale is increased since the output rms noise remains constant as the input full-scale increases).
[3]For these filter notch frequencies, the output rms noise is dominated by quantization noise and as a result is proportional to the value of the reference voltage.

Table IIa. Effective Resolution vs. Gain and First Notch Frequency for AD7713

First Notch of Filter and O/P Data Rate	−3 dB Frequency	Effective Resolution[1] (Bits)							
		Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128

100 Hz	26.2 Hz	13	13	13	13	13	12.5	12.5	12.5
200 Hz	52.4 Hz	10.5	10.5	11	11	11	10.5	10	10

NOTE
[1]Effective resolution is defined as the magnitude of the output rms noise with respect to the input full scale (i.e., 2 × V_{REF}/GAIN). The above table applies for a V_{REF} of +2.5 V and resolution numbers are rounded to the nearest 0.5 LSB.

CIRCUIT DESCRIPTION

The AD7711/AD7713 is a sigma-delta A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those in industrial control or process control applications. It contains a sigma-delta (or charge-balancing) ADC, a calibration microcontroller with on-chip static RAM, a clock oscillator, a digital filter and a bidirectional serial communications port.

The AD7711 contains two programmable gain input channels, one differential and one single-ended. The AD7713 contains three programmable gain analog input channels, two differential input and one high-level single-ended input. The gain range on all inputs is from 1 to 128. For the low-level inputs, this means that the input can accept unipolar signals of between 0 mV to +20 mV and 0 V to +2.5 V or bipolar signals in the range from ±20 mV to ±2.5 V when the reference input voltage equals +2.5 V. The input voltage range for the AIN3 of the AD7713 input is $+4 \times V_{REF}/GAIN$ and is 0 V to +10 V with the nominal reference of +2.5 V and a gain of 1. The input signal to the selected analog input channel is continuously sampled at a rate determined by the frequency of the master clock, CLK IN, and the selected gain (see Table III). A charge balancing A/D converter (Sigma-Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. The programmable gain function on the analog input is also incorporated in this sigma-delta modulator with the input sampling frequency being modified to give the higher gains. A $sinc^3$ digital low-pass filter processes the output of the sigma-delta modulator and updates the output register at a rate determined by the first notch frequency of this filter. The output data can be read from the serial port randomly or periodically at any rate up to the output register update rate. The first notch of this digital filter (and hence its −3 dB frequency) can be programmed via an on-chip control register.

The AD7711/AD7713 provides a number of calibration options which can be programmed via the on-chip control register. A calibration cycle may be initiated at any time by writing to this control register. The part can perform self-calibration using the on-chip calibration microcontroller and SRAM to store calibration parameters. Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel using the system calibration mode. Another option is a background calibration mode where the part continuously performs self-calibration and updates the calibration coefficients. Once the part is in this mode, the user does not have to worry about issuing periodic calibration commands to the device or asking the device to recalibrate when there is a change in the ambient temperature or power supply voltage.

The AD7711/AD7713 gives the user access to the on-chip calibration registers allowing the microprocessor to read the device's calibration coefficients and also to write its own calibration coefficients to the part from prestored values in E^2PROM. This gives the microprocessor much greater control over the part's calibration procedure. It also means that the user can verify that the device has performed its calibration correctly by comparing the coefficients after calibration with prestored values in E^2PROM.

The AD7713 is a positive supply only part while the AD7711 can be operated from positive and negative supplies. For battery operation or low power systems, both parts offer a standby mode that reduces idle power consumption to 300 μW typical on AD7713 and 7 mW typical on the AD7711.

The AD7711/AD7713 uses a second-order sigma-delta modulator and a digital filter that provides a rolling average of the sampled output. After power-up or if there is a step change in the input voltage, there is a settling time that must elapse before valid data is obtained.

Input Sample Rate

The modulator sample frequency for the device remains at $f_{CLK\ IN}/512$ (3.9 kHz @ $f_{CLK\ IN}$ = 2 MHz and 19.5 kHz @ f_{CLKIN} = 10 MHz) regardless of the selected gain. However, gains greater than ×1 are achieved by a combination of multiple input samples per modulator cycle and a scaling of the ratio of reference capacitor to input capacitor. As a result of the multiple sampling, the input sample rate of the device varies with the selected gain (see Table III). The effective input impedance is $1/C \cdot f_S$ where C is the input sampling capacitance and f_S is the input sample rate.

Table III. Input Sampling Frequency vs. Gain

Gain	Input Sampling Frequency (f_S)
1	$f_{CLK\ IN}/512$
2	$2 \times f_{CLK\ IN}/512$
4	$4 \times f_{CLK\ IN}/512$
8	$8 \times f_{CLK\ IN}/512$
16	$8 \times f_{CLK\ IN}/512$
32	$8 \times f_{CLK\ IN}/512$
64	$8 \times f_{CLK\ IN}/512$
128	$8 \times f_{CLK\ IN}/512$

DIGITAL FILTERING

The part's digital filter behaves like a similar analog filter, with a few minor differences.

First, since digital filtering occurs after the A-to-D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. To alleviate this problem, the part has over-range headroom built into the sigma-delta modulator and digital filter which allows overrange excursions of 5% above the analog input range. If noise signals are larger than this, consideration should be given to analog input filtering, or to reducing the input channel voltage so that its full scale is half that of the analog input channel full scale. This will provide an overrange capability greater than 100% at the expense of reducing the dynamic range by 1 bit (50%).

Filter Characteristics

The cutoff frequency of the digital filter is determined by the value loaded to bits FS0 to FS11 in the control register. At a clock frequency of 2 MHz, the minimum cutoff frequency of the filter is 0.52 Hz while the maximum programmable cutoff frequency is 53.9 Hz. At a clock frequency of 10 MHz (AD7711 only), the minimum cutoff frequency of the filter is 2.58 Hz while the maximum programmable cutoff frequency is 269 Hz.

Figure 2 shows the filter frequency response for a cutoff frequency of 2.62 Hz which corresponds to a first filter notch frequency of 10 Hz. This is a $(\sin x/x)^3$ response (also called $sinc^3$) that provides >100 dB of 50 Hz and 60 Hz rejection. Programming a different cutoff frequency via FS0–FS11 does not alter

the profile of the filter response, it changes the frequency of the notches as outlined in the Control Register section.

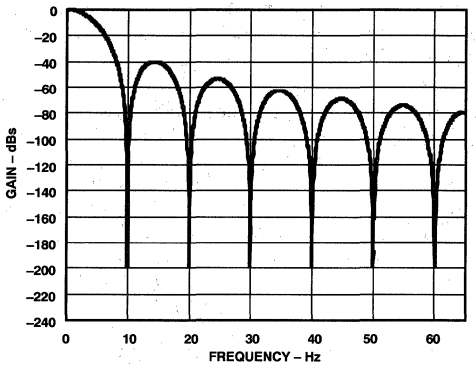

Figure 2. Frequency Response of AD7711/AD7713 Filter

Since the AD7711/AD7713 contains this on-chip, low-pass filtering, there is a settling time associated with step function inputs and data on the output will be invalid after a step change until the settling time has elapsed. The settling time depends upon the notch frequency chosen for the filter. The output data rate equates to this filter notch frequency and the settling time of the filter to a full-scale step input is 4 times the output data period. In applications using both input channels, the settling time of the filter must be allowed to elapse before data from the second channel is accessed.

Post Filtering

The on-chip modulator provides samples at a 3.9 kHz output rate (2 MHz clock) and 19.5 kHz (10 MHz clock). The on-chip digital filter decimates these samples to provide data at an output rate which corresponds to the programmed first notch frequency of the filter. Since the output data rate exceeds the Nyquist criterion, the output rate for a given bandwidth will satisfy most application requirements. However, there may be some applications which require a higher data rate for a given bandwidth and noise performance. Applications which need this higher data rate will require some post filtering following the digital filter of the AD7711/AD7713.

For example, if the required bandwidth is 7.86 Hz but the required update rate is 100 Hz, the data can be taken from the AD7711/AD7713 at the 100 Hz rate giving a −3 dB bandwidth of 26.2 Hz. Post filtering can be applied to this to reduce the bandwidth and output noise, to the 7.86 Hz bandwidth level, while maintaining an output rate of 100 Hz.

Post filtering can also be used to reduce the output noise from the device for low bandwidths. Noise in these bandwidths is essentially device noise or white noise, and since the input is chopped, the noise has a flat frequency response. By reducing the bandwidth, the noise in the resultant passband can be reduced. A reduction in bandwidth by a factor of 2 results in a $\sqrt{2}$ reduction in the output rms noise. This additional filtering will result in a longer settling time.

Antialias Considerations

The digital filter does not provide any rejection at integer multiples of the modulator sample frequency. This means that there are frequency bands, $\pm f_{3\ dB}$ wide ($f_{3\ dB}$ is cutoff frequency selected by FS0 to FS11) where noise passes unattenuated to the output. However, due to the part's high oversampling ratio, these bands occupy only a small fraction of the spectrum and most broadband noise is filtered. In any case, because of the high oversampling ratio a simple, RC, single-pole filter is generally sufficient to attenuate the signals in these bands on the analog input and thus provide adequate antialiasing filtering.

If passive components are placed in front of the AIN1 and AIN2 inputs of the AD7711/AD7713, care must be taken to ensure that the source impedance is low enough so as not to introduce gain errors in the system. The dc input impedance for the AIN1 and AIN2 inputs is over 1 GΩ. The input appears as a dynamic load which varies with the clock frequency and with the selected gain (see Figure 3). The input sample rate, as shown in Table III, determines the time allowed for the analog input capacitor, C_{IN}, to be charged. External impedances result in a longer charge time for this capacitor and this may result in gain errors being introduced on the analog inputs. Both inputs of the differential input channels look into similar input circuitry.

In any case, the error introduced due to longer charging times is a gain error which can be removed using the system calibration capabilities of the AD7711/AD7713 provided that the resultant span is within the span limits of the system calibration techniques for the AD7711/AD7713.

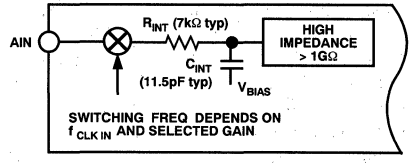

Figure 3. AIN1, AIN2 Input Impedance

The AIN3 input of the AD7713 contains a resistive attenuation network as outlined in Figure 4. The typical input impedance on this input is 44 kΩ. As a result, the AIN3 input of the AD7713 should be driven from a low impedance source.

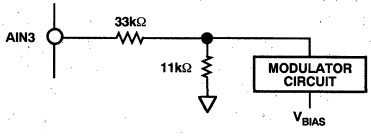

Figure 4. AIN3 Input Impedance

ANALOG INPUT FUNCTIONS

Analog Input Ranges

Both analog inputs on the AD7711 are programmable-gain, input channels which can handle either unipolar or bipolar input signals. The AIN1 channel of the AD7711 is a differential input channel having a common-mode range from V_{SS} to AV_{DD}, provided that the absolute value of the analog input voltage lies between V_{SS} − 30 mV and AV_{DD} + 30 mV. The AIN2 input channel is a single-ended input that is referred to AGND.

The analog inputs on the AD7713 provide the user with considerable flexibility in terms of analog input voltage ranges. Two of the inputs are differential, programmable-gain, input channels which can handle either unipolar or bipolar input signals. The common-mode range of these inputs is from AGND to AV_{DD}

provided that the absolute value of the analog input voltage lies between AGND −30 mV and AV_{DD}+30 mV. The third analog input is a single-ended, programmable gain high-level input which accepts analog input ranges of 0 to +4 × V_{REF}/GAIN.

The dc input leakage current on the AIN1 and AIN2 inputs is 10 pA maximum at 25°C (±1 nA over temperature). This results in a dc offset voltage developed across the source impedance. However, this dc offset effect can be compensated for by a combination of the differential input capability of the part and its system calibration mode. The dc input current on the AIN3 of the AD7713 input depends on the input voltage, For the nominal input voltage range of +10 V, the input current is 225 μA typ.

Burn Out Current

The AIN1(+) input of the AD7711/AD7713 contains a current source which can be turned on/off via the control register. This current source can be used in checking that a transducer has not burnt out or gone open circuit before attempting to take measurements on that channel. If the current is turned on and is allowed flow into the transducer and a measurement of the input voltage on the AIN1 input is taken, it can indicate that the transducer is not functioning correctly. For normal operation, this burn out current is turned off by writing a 0 to the BO bit in the control register. The burn-out current is 1 μA for the AD7711 and 200 nA for the AD7713.

RTD Excitation Currents

The AD7711/AD7713 also contains two matched 200 μA constant current sources which are provided at the RTD1 and RTD2 pins of the device. These currents can be turned on/off via the control register. Writing a 1 to the RO bit of the control register enables these excitation currents.

For four-wire RTD applications, one of these excitation currents is used to provide the excitation current for the RTD, the second current source can be left unconnected. For three-wire RTD configurations, the second on-chip current source can be used to eliminate errors due to voltage drops across lead resistances.

The temperature coefficient of the RTD current sources is typically 20 ppm/°C with a typical matching between the temperature coefficients of both current sources of 3 ppm/°C. For applications where the absolute value of the temperature coefficient is too large, the following schemes can be used to remove the drift error.

The conversion result from the AD7711/AD7713 is ratiometric to the V_{REF} voltage. Therefore, if the V_{REF} voltage varies with the RTD temperature coefficient, the temperature drift from the current source will be removed. For four-wire RTD applications, the reference voltage can be made ratiometric to RTD current source by using the second current with a low TC resistor to generate the reference voltage for the part. In this case if a 12.5 kΩ resistor is used, the 200 μA current source generates +2.5 V across the resistor. This +2.5 V can be applied to the REF IN(+) input of the part and with the REF IN(−) input at ground it will supply a V_{REF} of 2.5 V for the part. For three-wire RTD configurations, the reference voltage for the part is generated by placing a low TC resistor (12.5 kΩ for 2.5 V reference) in series with one of the constant current sources. The RTD current sources can be driven to within 2 V of AV_{DD}. The reference input of the part is differential so the REF IN(+) and REF IN(−) of the part are driven from either side of the resistor. Both schemes ensure that the reference voltage for the part tracks the RTD current sources over temperature and, thereby, removes the temperature drift error.

Bipolar/Unipolar Inputs

The AIN1 and AIN2 inputs on both parts can accept either unipolar or bipolar input voltage ranges while the AIN3 of the AD7713 accepts only unipolar signals. Bipolar or unipolar options for AIN1 and AIN2 are chosen by programming the B/U bit of the control register. This programs both channels for either unipolar or bipolar operation. Programming the part for either unipolar or bipolar operation does not change any of the input signal conditioning; it simply changes the data output coding. The data coding is binary for unipolar inputs and offset binary for bipolar inputs.

The AIN1 and AIN2 channels of the AD7713 and the AIN1 input of the AD7711 are differential, and as a result, the voltage to which the unipolar and bipolar signals are referenced is the voltage on the respective AIN(−) input. For example, if AIN(−) is +1.25 V and the part is configured for unipolar operation with a gain of 1 and a V_{REF} of +2.5 V, the input voltage range on the AIN(+) input is +1.25 V to +3.75 V. For the AIN3 input of the AD7713 and the AIN2 input of the AD7711, the input signals are referenced to AGND.

REFERENCE INPUT

The reference inputs of the part, REF IN(+) and REF IN(−), provide a differential reference input capability. The common-mode range for these differential inputs is from V_{SS} to AV_{DD} (AGND to AV_{DD} on AD7713). The nominal differential voltage, V_{REF} (REF IN(+) − REF IN(−)), is +2.5 V for specified operation but the reference voltage can go to +5 V with no degradation in performance provided that the absolute value of REF IN(+) and REF IN(−) does not exceed its supply limits. The part is also functional with V_{REF} voltages down to 1 V but with degraded performance as the output noise will, in terms of LSB size, be larger. REF IN(+) must always be greater than REF IN(−) for correct operation of the AD7711/AD7713.

Both reference inputs provide a high impedance, dynamic load similar to the analog inputs. The maximum dc input leakage current is 10 pA (±1 nA over temperature) and source resistance may result in gain errors on the part. The reference inputs look like the AIN1 analog input (see Figure 3). In this case, R_{INT} is 5 kΩ typ and C_{INT} varies with gain. The input sample rate is $f_{CLK\ IN}$/512 and does not vary with gain. For gains of 1 to 8 C_{INT} is 20 pF; for a gain of 16 it is 10 pF, for a gain of 32 it is 5 pF, for a gain of 64 it is 2.5 pF, and for a gain of 128 it is 1.25 pF.

The digital filter of the part removes noise from the reference input just as it does with the analog input, and the same limitations apply regarding lack of noise rejection at integer multiples of the sampling frequency. The output noise performance outlined in Tables I and II assumes a clean reference. If the reference noise in the bandwidth of interest is excessive, it can degrade the performance of the AD7711/AD7713. Recommended references for the AD7711/AD7713 are the AD680 and AD780, +2.5 V references.

REFERENCE OUTPUT (AD7711 ONLY)

The AD7711 contains a temperature compensated +2.5 V reference which has an initial tolerance of ±4%. This reference voltage is provided at the REF OUT pin, and it can be used as the reference voltage for the part by connecting REF OUT to the REF IN(+) pin. This REF OUT pin is a single-ended output, referenced to AGND, which is capable of providing up to 1 mA to an external load. In applications where REF OUT is connected

directly to REF IN(+), REF IN(−) should be tied to AGND to provide the nominal +2.5 V reference for the AD7711.

Using the on-chip reference as the reference source for the part results in somewhat degraded output noise performance from the AD7711 for portions of the noise table that are dominated by the device noise. The on-chip reference noise effect is eliminated in ratiometric applications where the reference is used to provide the excitation voltage for the analog front end.

V_{BIAS} Input (AD7711 only)

The V_{BIAS} input determines at what voltage the internal analog circuitry is biased. It essentially provides the return path for analog currents flowing in the modulator and, as such, it should be driven from a low impedance point to minimize errors.

For maximum internal headroom, the V_{BIAS} voltage should be set halfway between AV_{DD} and V_{SS}. The difference between AV_{DD} and (V_{BIAS} + 0.85 × V_{REF}) determines the amount of headroom the circuit has at the upper end, while the difference between V_{SS} and (V_{BIAS} − 0.85 × V_{REF}) determines the amount of headroom the circuit has at the lower end. Care should be taken in choosing a V_{BIAS} voltage to ensure that it stays within prescribed limits. For single +5 V operation, the selected V_{BIAS} voltage must ensure that V_{BIAS} ± 0.85 × V_{REF} does not exceed AV_{DD} or V_{SS} or that the V_{BIAS} voltage itself is greater than V_{SS} + 2.1 V and less than AV_{DD} − 2.1 V. For single +10 V operation or dual ±5 V operation, the selected V_{BIAS} voltage must ensure that V_{BIAS} × 0.85 × V_{REF} does not exceed AV_{DD} or V_{SS} or that the V_{BIAS} voltage itself is greater than V_{SS} + 3 V or less than AV_{DD} − 3 V. For example, with AV_{DD} = +4.75 V, V_{SS} = 0 V and V_{REF} = +2.5 V, the allowable range for the V_{BIAS} voltage is +2.125 V to +2.625 V. With AV_{DD} = +9.5 V, V_{SS} = 0 V and V_{REF} = 5 V, the range for V_{BIAS} is +4.25 V to +5.25 V. With AV_{DD} = +4.75 V, V_{SS} = −4.75 V and V_{REF} = +2.5 V, the V_{BIAS} range is −2.625 V to +2.625 V.

The V_{BIAS} voltage does have an effect on the AV_{DD} power supply rejection performance of the AD7711. If the V_{BIAS} voltage tracks the AV_{DD} supply, it improves the power supply rejection from the AV_{DD} supply line from 80 dB to 95 dB. Using an external Zener diode, connected between the AV_{DD} line and V_{BIAS}, as the source for the V_{BIAS} voltage gives the improvement in AV_{DD} power supply rejection performance.

USING THE AD7711/AD7713

SYSTEM DESIGN CONSIDERATIONS

The AD7711/AD7713 operates differently from successive approximation ADCs or integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The output register is updated at a rate determined by the first notch of the filter and the output can be read at any time, either synchronously or asynchronously.

Clocking

The AD7711/AD7713 requires a master clock input, which may be an external TTL/CMOS compatible clock signal applied to the MCLK IN pin with the MCLK OUT pin left unconnected. Alternatively, a crystal of the correct frequency can be connected between MCLK IN and MCLK OUT, in which case the clock circuit will function as a crystal controlled oscillator. For lower clock frequencies, a ceramic resonator may be used instead of the crystal. For these lower frequency oscillators, external capacitors may be required on either the ceramic resonator or on the crystal.

The input sampling frequency, the modulator sampling frequency, the −3 dB frequency, output update rate and calibration time are all directly related to the master clock frequency, $f_{CLK\ IN}$. Reducing the master clock frequency by a factor of 2 will halve the above frequencies and update rate and will double the calibration time.

The current drawn from the DV_{DD} power supply is also directly related to $f_{CLK\ IN}$. Reducing $f_{CLK\ IN}$ by a factor of 2 will halve the DV_{DD} current but will not affect the current drawn from the AV_{DD} power supply.

System Synchronization

If multiple AD7711/AD7713s are operated from a common master clock, they can be synchronized to update their output registers simultaneously. A falling edge on the $\overline{SYNC}$ input resets the filter and places the part into a consistent, known state. A common signal to the parts' $\overline{SYNC}$ inputs will synchronize their operation. This would normally be done after each AD7711/AD7713 has performed its own calibration or has had calibration coefficients loaded to it.

The $\overline{SYNC}$ input can also be used to reset the digital filter in systems where the turn-on time of the digital power supply (DV_{DD}) is very long. In such cases, the AD7711/AD7713 will start operating internally before the DV_{DD} line has reached its minimum operating level, +4.75 V. With a low DV_{DD} voltage, the part's internal digital filter logic does not operate correctly. Thus, the AD7711/AD7713 may have clocked itself into an incorrect operating condition by the time that DV_{DD} has reached its correct level. The digital filter will be reset upon issue of a calibration command (whether it is self-calibration, system calibration or background calibration) to the AD7711/AD7713. This ensures correct operation of the AD7711/AD7713. In systems where the power-on default conditions of the part are acceptable and no calibration is performed after power-on, issuing a $\overline{SYNC}$ pulse to the part will reset the AD7711/AD7713's digital filter logic. An R, C on the $\overline{SYNC}$ line, with R, C time constant longer than the DV_{DD} power-on time, will perform the $\overline{SYNC}$ function.

ACCURACY

Sigma-Delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no missing codes performance. The AD7711/AD7713 achieves excellent linearity by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient. The device also achieves low input drift through the use of chopper-stabilized techniques in its input stage. To ensure excellent performance over time and temperature, the AD7711/AD7713 uses digital calibration techniques which minimize offset and gain error.

AUTOCALIBRATION

Autocalibration on the AD7711/AD7713 removes offset and gain errors from the device. A calibration routine should be initiated on the device whenever there is a change in the ambient operating temperature or supply voltage. It should also be initiated if there is a change in the selected gain, filter notch or bipolar/unipolar input range. However, if the AD7711/AD7713 is in its background calibration mode, the above changes are all automatically taken care of (after the settling time of the filter has been allowed for).

The AD7711/AD7713 offers self-calibration, system calibration and background calibration facilities. For calibration to occur on the selected channel, the on-chip microcontroller must record the modulator output for two different input conditions. These are "zero-scale" and "full-scale" points. With these readings, the microcontroller can calculate the gain slope for the input to output transfer function of the converter. Internally, the part works with a resolution of 33 bits to determine its conversion result of either 16 bits or 24 bits.

The part also provides the facility to write to the on-chip calibration registers and in this manner the span and offset for the part can be adjusted by the user. The offset calibration register contains a value which is subtracted from all conversion results, while the full-scale calibration register contains a value which is multiplied by all conversion results. The offset calibration coefficient is subtracted from the result prior to the multiplication by the full-scale coefficient. In the first three modes outlined here, the $\overline{DRDY}$ line indicates that calibration is complete by going low. If $\overline{DRDY}$ is low before (or goes low during) the calibration command, it may take up to one modulator cycle before $\overline{DRDY}$ goes high to indicate that calibration is in progress. Therefore, $\overline{DRDY}$ should be ignored for up to one modulator cycle after the last bit of the calibration command is written to the control register.

Self-Calibration

In the self-calibration mode with a unipolar input range, the zero-scale point used in determining the calibration coefficients is with both inputs shorted (i.e., AIN(+) = AIN(−) = V_{BIAS} for the differential inputs and AIN = V_{BIAS} for AIN2 of the AD7711 and AIN3 of the AD7713) and the full-scale point is V_{REF}. The zero-scale coefficient is determined by converting an internal shorted inputs node. The full-scale coefficient is determined from the span between this shorted inputs conversion and a conversion on an internal V_{REF} node. The self-calibration mode is invoked by writing the appropriate values (0, 0, 1) to the MD2, MD1 and MD0 bits of the control register. In this calibration mode, the shorted inputs node is switched in to the modulator first and a conversion is performed; the V_{REF} node is then switched in and another conversion is performed. When the calibration sequence is complete, the calibration coefficients updated and the filter resettled to the analog input voltage, the $\overline{DRDY}$ output goes low. The self-calibration procedure takes into account the selected gain on the PGA.

For bipolar input ranges in the self-calibrating mode, the sequence is very similar to that just outlined. In this case, the two points which the AD7711/AD7713 calibrates are midscale (bipolar zero) and positive full scale.

System Calibration

System calibration allows the AD7711/AD7713 to compensate for system gain and offset errors as well as its own internal errors. System calibration performs the same slope factor calculations as self-calibration but uses voltage values presented by the system to the AIN inputs for the zero and full-scale points. System calibration is a two-step process. The zero-scale point must be presented to the converter first. It must be applied to the converter before the calibration step is initiated and remain stable until the step is complete. System calibration is initiated by writing the appropriate values (0, 1, 0) to the MD2, MD1 and MD0 bits of the control register. The $\overline{DRDY}$ output from the device will signal when the step is complete by going low. After the zero-scale point is calibrated, the full-scale point is applied and the second step of the calibration process is initiated by again writing the appropriate values (0, 1, 1) to MD2, MD1 and MD0. Again the full-scale voltage must be set up before the calibration is initiated and it must remain stable throughout the calibration step. $\overline{DRDY}$ goes low at the end of this second step to indicate that the system calibration is complete. In the unipolar mode, the system calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

This two-step system calibration mode offers another feature. After the sequence has been completed, additional offset or gain calibrations can be performed by themselves to adjust the zero reference point or the system gain. This is achieved by performing the first step of the system calibration sequence (by writing 0, 1, 0 to MD2, MD1, MD0). This will adjust the zero scale or offset point but will not change the slope factor from what was set during a full system calibration sequence.

System calibration can also be used to remove any errors from an antialiasing filter on the analog input. A simple R, C antialiasing filter on the front end may introduce a gain error on the analog input voltage but the system calibration can be used to remove this error.

System Offset Calibration

System offset calibration is a variation of both the system calibration and self-calibration. In this case, the zero-scale point for the system is presented to the AIN input of the converter. System offset calibration is initiated by writing 1, 0, 0 to MD2, MD1, MD0. The system zero-scale coefficient is determined by converting the voltage applied to the AIN input, while the full-scale coefficient is determined from the span between this AIN conversion and a conversion on V_{REF}. The zero-scale point should be applied to the AIN input for the duration of the calibration sequence. This is a one-step calibration sequence with $\overline{DRDY}$ going low when the sequence is completed. In the unipolar mode, the system offset calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

Background Calibration

The AD7711/AD7713 also offers a background calibration mode where the part interleaves its calibration procedure with its normal conversion sequence. In the background calibration mode, the same voltages are used as the calibration points as are used in the self-calibration mode, i.e., shorted inputs and V_{REF}. The background calibration mode is invoked by writing 1, 0, 1 to MD2, MD1, MD0 of the control register. When invoked, the background calibration mode reduces the output data rate of the part by a factor of six while the −3 dB bandwidth remains unchanged. Its advantage is that the part is continually performing calibration and automatically updating its calibration coefficients. As a result, the effects of temperature drift, supply sensitivity and time drift on zero and full-scale errors are automatically removed. When the background calibration mode is turned on, the part will remain in this mode until bits MD2, MD1 and MD0 of the control register are changed. With background calibration mode on, the first result from the AD7711/AD7713 will be incorrect as the full-scale calibration will not have been performed. For a step change on the input, the second output update will have settled to 100% of the final value.

Table IV summarizes the calibration modes and the calibration points associated with them. It also gives the duration from

when the calibration is invoked to when valid data is available to the user.

Span and Offset Limits

Whenever a system calibration mode is used, there are limits on the amount of offset and span that can be accommodated. The range of input span in both the unipolar and bipolar modes for the AIN1 and AIN2 inputs of both the AD7711 and AD7713 has a minimum value of $0.8 \times V_{REF}/GAIN$ and a maximum value of $2.1 \times V_{REF}/GAIN$. For AIN3 of the AD7713, the minimum value is $3.2 \times V_{REF}/GAIN$ while the maximum value is $4.2 \times V_{REF}/GAIN$.

The amount of offset that can be accommodated depends on whether the unipolar or bipolar mode is being used. This offset range is limited by the requirement that the positive full-scale calibration limit is $\leq 1.05 \times V_{REF}/GAIN$ for AIN1 and AIN2. Therefore, the offset range plus the span range cannot exceed $1.05 \times V_{REF}/GAIN$ for AIN1 and AIN2. If the span is at its minimum ($0.8 \times V_{REF}/GAIN$) the maximum the offset can be is ($0.25 \times V_{REF}/GAIN$) for AIN1 and AIN2. For AIN3, both ranges are multiplied by a factor of 4.

In the bipolar mode, the system offset calibration range is again restricted by the span range. The span range of the converter in bipolar mode is equidistant around the voltage used for the zero-scale point thus the offset range plus half the span range cannot exceed ($1.05 \times V_{REF}/GAIN$) for AIN1 and AIN2. If the span is set to $2 \times V_{REF}/GAIN$, the offset span cannot move more than $\pm(0.05 \times V_{REF}/GAIN)$ before the endpoints of the transfer function exceed the input overrange limits $\pm(1.05 \times V_{REF}/GAIN)$ for AIN1. If the span range is set to the minimum $\pm(0.4 \times V_{REF}/GAIN)$ the maximum allowable offset range is $\pm(0.65 \times V_{REF}/GAIN)$ for AIN1 and AIN2. The AIN3 input can only be used in the unipolar mode.

Table IV. Calibration Truth Table

Cal Type	MD2, MD1, MD0	Zero-Scale Cal	Full-Scale Cal	Sequence	Duration
Self-Cal	0, 0, 1	Shorted Inputs	V_{REF}	One Step	9 × 1/Output Rate
System Cal	0, 1, 0	AIN		Two Step	4 × 1/Output Rate
System Cal	0, 1, 1		AIN	Two Step	4 × 1/Output Rate
System Offset Cal	1, 0, 0	AIN	V_{REF}	One Step	9 × 1/Output Rate
Background Cal	1, 0, 1	Shorted Inputs	V_{REF}	One Step	6 × 1/Output Rate

POWER-UP AND CALIBRATION

On power-up, the AD7711/AD7713 performs an internal reset which sets the contents of the control register to a known state. However, to ensure correct calibration for the device, a calibration routine should be performed after power-up.

The power dissipation and temperature drift of the part are low and no warm-up time is required before the initial calibration is performed. However, the external reference must have stabilized before calibration is initiated.

Drift Considerations

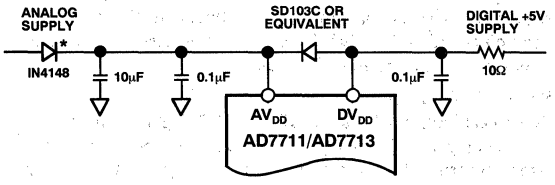
The AD7711/AD7713 uses chopper stabilization techniques to minimize input offset drift. Charge injection in the analog switches and dc leakage currents at the sampling node are the primary sources of offset voltage drift in the converter. The dc input leakage current is essentially independent of the selected gain. Gain drift within the converter depends primarily upon the temperature tracking of the internal capacitors. It is not affected by leakage currents.

Measurement errors due to offset drift or gain drift can be eliminated at any time by recalibrating the converter or by operating the part in the background calibration mode. Using the system calibration mode can also minimize offset and gain errors in the signal conditioning circuitry. Integral and differential linearity errors are not significantly affected by temperature changes.

POWER SUPPLIES AND GROUNDING

The analog and digital supplies to the AD7711/AD7713 are independent and separately pinned out to minimize coupling between the analog and digital sections of the device. The digital filter will provide rejection of broadband noise on the power supplies, except at integer multiples of the modulator sampling frequency. The digital supply (DV_{DD}) must never exceed the analog positive supply (AV_{DD}) by more than 0.3 V. Power supply sequencing is, therefore, important. If separate analog and digital supplies are used, care must be taken to ensure that the analog supply is powered up first. If this cannot be ensured or if DV_{DD} can exceed AV_{DD} at any other time, the protection scheme outlined in Figure 5 is recommended to protect the device. In systems where $AV_{DD} = +5$ V and $DV_{DD} = +5$ V, it is recommended that AV_{DD} and DV_{DD} are driven from the same +5 V supply, although each supply should be decoupled separately. It is preferable that the common supply is the system's analog +5 V supply.

It is also important that power is applied to the AD7711/AD7713 before signals at REF IN, AIN or the logic input pins in order to avoid latch-up. If separate supplies are used for the AD7711/AD7713 and the system digital circuitry, then the AD7711/AD7713 should be powered up first. If it is not possible to guarantee this, then current limiting resistors should be placed in series with the logic inputs.



*THIS DIODE MAY BE NECESSARY IF THE SHORT-CIRCUIT CURRENT FROM THE DIGITAL SUPPLY IS TOO LARGE FOR THE SD103C.

Figure 5. Protection Scheme for DV_{DD} Powering-Up Before AV_{DD}

DIGITAL INTERFACE

The digital interface section for the AD7711/AD7713 is identical to that outlined in the DIGITAL INTERFACE section of the AD7710/AD7712 data sheet.

LC²MOS Signal Conditioning ADC with RTD Current Source

AD7711A*

FEATURES

Charge Balancing ADC
- **24 Bits No Missing Codes**
- **±0.0015% Nonlinearity**

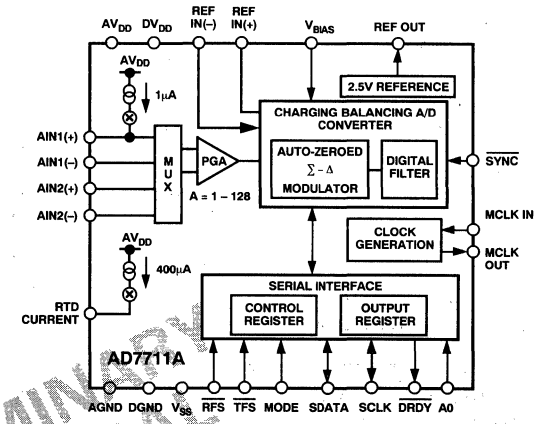
Two-Channel Programmable Gain Front End
- **Gains from 1 to 128**
- **Differential Inputs**

Low-Pass Filter with Programmable Filter Cutoffs
Ability to Read/Write Calibration Coefficients
Bidirectional Microcontroller Serial Interface
Internal/External Reference Option
Single or Dual Supply Operation
Low Power (25 mW typ) with Power-Down Mode (7 mW typ)

APPLICATIONS

RTD Transducers

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

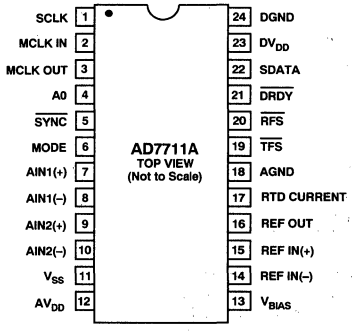
The AD7711A is a complete analog front end for low frequency measurement applications. The device accepts low level signals directly from a transducer and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 24 bits of no missing codes performance. The input signal is applied to a proprietary programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

The part features two differential analog inputs and a differential reference input. Normally, one of the channels will be used as the main channel with the second channel used as an auxiliary input to periodically measure a second voltage. It can be operated from a single supply (by tying the V_{SS} pin to AGND) provided that the input signals on the analog inputs are more positive than −30 mV. By taking the V_{SS} pin negative, the part can convert signals down to $-V_{REF}$ on its inputs. The part also provides a 400 μA current source that can be used to provide excitation for RTD transducers. The AD7711A thus performs all signal conditioning and conversion for a single or dual channel system.

The AD7711A is ideal for use in smart, microcontroller based systems. Input channel selection, gain settings and signal polarity can be configured in software using the bidirectional serial port. The AD7711A contains self-calibration, system calibration and background calibration options and also allows the user to read and write the on-chip calibration registers.

CMOS construction ensures low power dissipation and a software programmable power down mode reduces the standby power consumption to only 7 mW typical. The part is available in a 24-pin, 0.3 inch-wide, plastic and hermetic dual-in-line package (DIP) as well as a 24-lead small outline (SOIC) package.

PIN CONFIGURATION
DIP and SOIC



*Protected by U.S. Patent No. 5,134,401.

Load Regulation	1.5	mV/mA max	Maximum Load Current 1 mA
External Current	1	mA max	

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version −55°C to +125°C. See also Note 16.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors.

[6]This common-mode voltage range is allowed provided that the input voltage on AIN(+) and AIN(−) does not exceed AV_{DD} + 30 mV and V_{SS} − 30 mV.

[7]These numbers are guaranteed by design and/or characterization.

[8]The analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance depends on the selected gain (see Tables IV and V).

[9]The analog input voltage range on the AIN1(+) and AIN2(+) inputs is given here with respect to the voltage on the AIN1(−) and AIN2(−) inputs. The absolute voltage on the analog inputs should not go more positive than AV_{DD} + 30 mV or go more negative than V_{SS} − 30 mV.

[10]V_{REF} = REF IN(+) − REF IN(−).

[11]The reference input voltage range may be restricted by the input voltage range requirement on the V_{BIAS} input.

Parameter	A, S Versions[1]	Units	Conditions/Comments
V_{BIAS} INPUT[12]			
Input Voltage Range	$AV_{DD} - 0.85 \times V_{REF}$		See V_{BIAS} Input Section
	or $AV_{DD} - 3$	V max	Whichever Is Smaller; +5 V/−5 V or +10 V/0 V Nominal AV_{DD}/V_{SS}
	or $AV_{DD} - 2.1$	V max	Whichever Is Smaller; +5 V/0 V Nominal AV_{DD}/V_{SS}
	$V_{SS} + 0.85 \times V_{REF}$		See V_{BIAS} Input Section
	or $V_{SS} + 3$	V min	Whichever Is Greater; +5 V/−5 V or +10 V/0 V Nominal AV_{DD}/V_{SS}
	or $V_{SS} + 2.1$	V min	Whichever Is Greater; +5 V/0 V Nominal AV_{DD}/V_{SS}
V_{BIAS} Rejection	65 to 85	dB typ	Increasing with Gain
LOGIC INPUTS			
Input Current	±10	μA max	
All Inputs Except MCLK IN			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	2.0	V min	
MCLK IN Only			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	3.5	V min	
LOGIC OUTPUTS			
V_{OL}, Output Low Voltage	0.4	V max	I_{SINK} = 1.6 mA
V_{OH}, Output High Voltage	$DV_{DD} - 1$	V min	I_{SOURCE} = 100 μA
Floating State Leakage Current	±10	μA max	
Floating State Output Capacitance[13]	9	pF typ	
TRANSDUCER BURN-OUT			
Current	100	nA nom	
Initial Tolerance	±10	% typ	
Drift	0.1	%/°C typ	
RTD EXCITATION CURRENT			
Output Current	400	μA nom	
Initial Tolerance	±20	μA max	
Drift	20	ppm/°C typ	
Line Regulation (AV_{DD})	400	nA/V max	AV_{DD} = +5 V
Load Regulation	400	nA/V max	
Output Compliance	$AV_{DD} - 2$	V max	
SYSTEM CALIBRATION			
Positive Full-Scale Calibration Limit[14]	$(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Negative Full-Scale Calibration Limit[14]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Offset Calibration Limit[15]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Input Span[15]	$0.8 \times V_{REF}/GAIN$	V min	GAIN Is the Selected PGA Gain (Between 1 and 128)
	$(2.1 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)

NOTES

[12]The AD7711A is tested with the following V_{BIAS} voltages. With AV_{DD} = +5 V and V_{SS} = 0 V, V_{BIAS} = +2.5 V; with AV_{DD} = +10 V and V_{SS} = 0 V, V_{BIAS} = +5 V and with AV_{DD} = +5 V and V_{SS} = −5 V, V_{BIAS} = 0 V.

[13]Sample tested at +25°C to ensure compliance.

[14]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale then the device will output all 0s.

[15]These calibration and span limits apply provided the absolute voltage on the analog inputs does not exceed AV_{DD} + 30 mV or go more negative than V_{SS} − 30 mV. The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

AD7711A—SPECIFICATIONS

Parameter	A, S Versions[1]	Units	Conditions/Comments
POWER REQUIREMENTS			
Power Supply Voltages			
AV_{DD} Voltage[16]	+5 to +10	V nom	±5% for Specified Performance
DV_{DD} Voltage[17]	+5	V nom	±5% for Specified Performance
AV_{DD}–V_{SS} Voltage	+10.5	V max	For Specified Performance
Power Supply Currents			
AV_{DD} Current	4	mA max	
DV_{DD} Current	4.5	mA max	
V_{SS} Current	1.5	mA max	V_{SS} = −5 V
Power Supply Rejection[18]			Rejection w.r.t. AGND; Assumes V_{BIAS} Is Fixed
Positive Supply (AV_{DD})	See Note 19	dB typ	
Negative Supply (V_{SS})	90	dB typ	
Power Dissipation			
Normal Mode	45	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V; Typically 25 mW
Normal Mode	52.5	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = −5 V; Typically 30 mW
Standby (Power-Down) Mode	15	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V or −5 V; Typically 7 mW

NOTES

[16]The AD7711A is specified with a 10 MHz clock for AV_{DD} voltages of +5 V ±5%. It is specified with an 8 MHz clock for AV_{DD} voltages greater than 5.25 V and less than 10.5 V. Operation with AV_{DD} voltages in the range 5.25 V to 10.5 V is only guaranteed over the 0 to +70°C temperature range.

[17]The ±5% tolerance on the DV_{DD} input is allowed provided that DV_{DD} does not exceed AV_{DD} by more than 0.3 V.

[18]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 10 Hz, 25 Hz or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 10 Hz, 30 Hz or 60 Hz.

[19]PSRR depends on gain: Gain of 1: 70 dB typ; Gain of 2: 75 dB typ; Gain of 4: 80 dB typ; Gains of 8 to 128: 85 dB typ. These numbers can be improved (to 95 dB typ) by deriving the V_{BIAS} voltage (via Zener diode or reference) from the AV_{DD} supply.

Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of the specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model[1]	Temperature Range	Package Option[2]
AD7711AAN	−40°C to +85°C	N-24
AD7711AAR	−40°C to +85°C	R-24

NOTES

[2]N = Plastic DIP; R = SOIC. For outline information see Package Information section.

CONTROL REGISTER (24 BITS)

A write to the device with the A0 input low writes data to the control register. A read to the device with the A0 input low accesses the contents of the control register. The control register is 24-bits wide and when writing to the register 24 bits of data must be written otherwise the data will not be loaded to the control register. In other words, it is not possible to write just the first 12-bits of data into the control register. If more than 24 clock pulses are provided before $\overline{TFS}$ returns high, then all clock pulses after the 24th clock pulse are ignored. Similarly, a read operation from the control register should access 24 bits of data.

MSB

MD2	MD1	MD0	G2	G1	G0	CH	PD	WL	IO	BO	B/U

FS11*	FS10	FS9	FS8	FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0

LSB

*Must always be 0 to ensure correct operation of the device.

Operating Mode			
MD2	**MD1**	**MD0**	**Operating Mode**
0	0	0	Normal Mode. This is the normal mode of operation of the device whereby a read to the device with A0 high accesses data from the data register. This is the default condition of these bits after the internal power on reset.
0	0	1	Activate Self-Calibration. This activates self-calibration on the channel selected by CH. This is a one-step calibration sequence, and when complete, the part returns to normal mode (with MD2, MD1, MD0 of the control register returning to 0, 0, 0). The $\overline{DRDY}$ output indicates when this self-calibration is complete and valid data is available in the output register. For this calibration type, the zero scale calibration is done internally on shorted (zeroed) inputs and the full-scale calibration is done internally on V_{REF}.
0	1	0	Activate System Calibration. This activates system calibration on the channel selected by CH. This is a two-step calibration sequence, with the zero scale calibration done first on the selected input channel and $\overline{DRDY}$ indicating when this zero scale calibration is complete. The part returns to normal mode at the end of this first step in the two-step sequence.
0	1	1	Activate System Calibration. This is the second step of the system calibration sequence with full-scale calibration being performed on the selected input channel. Once again, $\overline{DRDY}$ indicates when the full-scale calibration is complete. When this calibration is complete, the part returns to normal mode.
1	0	0	Activate System Offset Calibration. This activates system offset calibration on the channel selected by CH. This is a one-step calibration sequence and, when complete, the part returns to normal mode with $\overline{DRDY}$ indicating when this system offset calibration is complete. For this calibration type, the zero scale calibration is done on the selected input channel and the full-scale calibration is done internally on V_{REF}.
1	0	1	Activate Background Calibration. This activates background calibration on the channel selected by CH. If the background calibration mode is on, then the AD7711A provides continuous self-calibration of the reference and shorted (zeroed) inputs. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the device when there is a change in the ambient temperature. In this mode, the shorted (zeroed) inputs and V_{REF}, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are automatically updated.
1	1	0	Read/Write Zero Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the zero scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the zero scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register. Therefore, when writing to the calibration register 24 bits of data must be written, otherwise the new data will not be transferred to the calibration register.
1	1	1	Read/Write Full-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the full-scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the full-scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register. Therefore, when writing to the calibration register 24 bits of data must be written, otherwise the new data will not be transferred to the calibration register.

Filter Selection (FS11–FS0)

The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$) filter response. The 12 bits of data programmed into these bits determine the filter cutoff frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device.

The first notch of the filter occurs at a frequency determined by the relationship: filter first notch frequency = $(f_{CLK\ IN}/512)/code$ where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 2,000. With the nominal $f_{CLK\ IN}$ of 10 MHz, this results in a first notch frequency range from 9.76 Hz to 1.028 kHz. To ensure correct operation of the AD7711A, the value of the code loaded to these bits must be within this range. Failure to do this will result in unspecified operation of the device.

Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I and II and Figure 2 show the effect of the filter notch frequency and gain on the effective resolution of the AD7711A. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 50 Hz, then a new word is available at a 50 Hz rate or every 20 ms. If the first notch is at 1 kHz, a new word is available every 1 ms.

The settling time of the filter to a full-scale step input change is worst case 4 × 1/(output data rate). This settling time is to 100% of the final value. For example, with the first filter notch at 50 Hz, the settling time of the filter to a full-scale step input change is 80 ms max. If the first notch is at 1 kHz, the settling time of the filter to a full-scale input step is 4 ms max. This settling time can be reduced to 3 × 1/(output data rate) by synchronizing the step input change to a reset of the digital filter. In other words, if the step input takes place with $\overline{SYNC}$ low, the settling time will be 3 × 1/(output data rate). If a change of channels takes place, the settling time is 3 × 1/(output data rate) regardless of the $\overline{SYNC}$ input.

The −3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter −3 dB frequency = 0.262 × first notch frequency.

All other features and functions of the AD7711A are as per the AD7710. Refer to the AD7710/AD7712 data sheet for detailed description.

3 V/5 V, CMOS, Low Cost, Low Power, Signal Conditioning ADC

AD7714*

FEATURES

Charge Balancing ADC
- 24 Bits No Missing Codes
- 0.0015% Nonlinearity

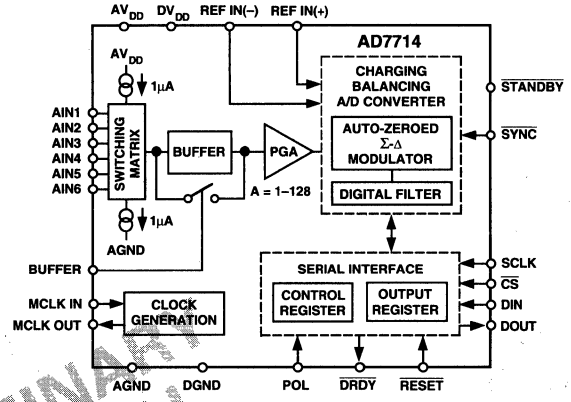
Five-Channel Programmable Gain Front End
- Gains from 1 to 128
- Can be Configured as Three Fully Differential Inputs or Five Pseudo-Differential Inputs

Three-Wire Serial Interface
3 V (AD7714-3) or 5 V (AD7714-5) Operation
Low Power (750 μW typ) with Power-Down (50 μW typ)
Low-Pass Filter with Programmable Filter Cutoffs
Ability to Read/Write Calibration Coefficients

APPLICATIONS

Portable Industrial Instruments
Portable Weigh Scales
Loop-Powered Systems
Smart Transmitters

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7714 is a complete analog front end for low frequency measurement applications. The device accepts low level signals directly from a transducer and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 24 bits of no missing codes performance. The input signal is applied to a proprietary programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

The part features three differential analog inputs (which can also be configured as five pseudo-differential analog inputs) as well as a differential reference input. It operates from a single supply (+3 V or +5 V). The AD7714 thus performs all signal conditioning and conversion for a system consisting of up to five channels.

The AD7714 is ideal for use in smart, microcontroller- or DSP-based systems. It features a serial interface that can be configured for three-wire operation. Gain settings, signal polarity and channel selection can be configured in software using the input serial port. The AD7714 contains self-calibration, system calibration and background calibration options and also allows the user to read and write the on-chip calibration registers.

CMOS construction ensures very low power dissipation, and the power-down mode reduces the standby power consumption to 50 μW typ. The part is available in a 24-pin, 0.3 inch-wide, plastic and hermetic dual-in-line package (DIP); a 24 lead small outline (SOIC) package and a 28-lead shrink small outline package (SSOP).

PRODUCT HIGHLIGHTS

1. The AD7714 consumes less than 500 μA ($f_{CLK\ IN}$ = 1 MHz) or 1 mA ($f_{CLK\ IN}$ = 2.5 MHz) in total supply current, making it ideal for use in loop-powered systems.
2. The programmable gain channels allow the AD7714 to accept input signals directly from a strain gage or transducer removing a considerable amount of signal conditioning.
3. The AD7714 is ideal for microcontroller or DSP processor applications with a three-wire serial interface reducing the number of interconnect lines and reducing the number of opto-couplers required in isolated systems. The part contains on-chip registers that allow control over filter cutoff, input gain, channel selection, signal polarity and calibration modes.
4. The part features excellent static performance specifications with 24-bit no missing codes, ±0.0015% accuracy and low rms noise (<300 mV). End-point errors and the effects of temperature drift are eliminated by on-chip self-calibration, which removes zero-scale and full-scale errors.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7714-5–SPECIFICATIONS

(AV_{DD} = +5 V, DV_{DD} = +3 V or +5 V, REF IN(+) = +2.5 V; REF IN(–) = AGND; $f_{CLK\ IN}$ = 2.4576 MHz unless otherwise stated. All specifications T_{MIN} to T_{MAX} unless otherwise noted.)

Parameter	A, S Versions[1]	Units	Conditions/Comments
STATIC PERFORMANCE			
No Missing Codes	24	Bits min	Guaranteed by Design. For Filter Notches ≤ 60 Hz
	22	Bits min	For Filter Notch = 100 Hz
	18	Bits min	For Filter Notch = 250 Hz
	15	Bits min	For Filter Notch = 500 Hz
	12	Bits min	For Filter Notch = 1 kHz
Output Noise	See Tables I & II		Depends on Filter Cutoffs and Selected Gain
Integral Nonlinearity	±0.0015	% of FSR max	Filter Notches ≤ 60 Hz

	0.4	mA max	Typically 0.3 mA. DV_{DD} = 5 V. $f_{CLK\,IN}$ = 1 MHz
	0.5	mA max	Typically 0.4 mA. DV_{DD} = 3 V. $f_{CLK\,IN}$ = 2.4576 MHz
	1	mA max	Typically 0.8 mA. DV_{DD} = 5 V. $f_{CLK\,IN}$ = 2.4576 MHz
Power Supply Rejection[18] (AVDD)	See Note 19	dB typ	
Normal Mode Power Dissipation			AV_{DD} = DV_{DD} = +3 V. Digital I/Ps = 0 V or DV_{DD}. BST Bit = 0
	1.5	mW max	Typically 1 mW. BUFFER = 0 V. $f_{CLK\,IN}$ = 1 MHz
	2.4	mW max	Typically 1.6 mW. BUFFER = +5 V. $f_{CLK\,IN}$ = 1 MHz
	3	mW max	Typically 2.1 mW. BUFFER = 0 V. $f_{CLK\,IN}$ = 2.4576 MHz
	4.5	mW max	Typically 3.6 mW. BUFFER = +5 V. $f_{CLK\,IN}$ = 2.4576 MHz
Normal Mode Power Dissipation			AV_{DD} = DV_{DD} = +5 V. Digital I/Ps = 0 V or DV_{DD}. BST Bit = 0
	3.5	mW max	Typically 2.5 mW. BUFFER = 0 V. $f_{CLK\,IN}$ = 1 MHz
	5	mW max	Typically 3.5 mW. BUFFER = +5 V. $f_{CLK\,IN}$ = 1 MHz
	7.5	mW max	Typically 5.5 mW. BUFFER = 0 V. $f_{CLK\,IN}$ = 2.4576 MHz
	10	mW max	Typically 8 mW. BUFFER = +5 V. $f_{CLK\,IN}$ = 2.4576 MHz
Standby (Power-Down) Dissipation	100	µW max	Typically 50 µW

NOTES

[1]Temperature ranges are as follows: A Version: –40°C to +85°C; S Version: –55°C to +125°C.

[2]Applies after calibration at the temperature of interest.

[3]These errors will be of the order of the output noise of the part as shown in Tables I to IV.

[4]Recalibration at any temperature will remove these drift errors.

[5]Positive Full-Scale Error includes Zero-Scale Errors (Unipolar Offset Error or Bipolar Zero Error) and applies to both unipolar and bipolar input ranges.

[6]Full-Scale Drift includes Zero-Scale Drift (Unipolar Offset Drift or Bipolar Zero Drift) and applies to both unipolar and bipolar input ranges.

[7]Gain Error does not include Zero-Scale Errors. It is calculated as Full-Scale Error—Unipolar Offset Error for unipolar ranges and Full-Scale Error—Bipolar Zero Error for bipolar ranges.

[8]Gain Drift does not include Unipolar Offset Drift/Bipolar Zero Drift. It is effectively the drift of the part if zero-scale calibrations only were performed as is the case with background calibration for gains of 64 and 128.

[9]This Common-Mode voltage range is allowed provided that the input voltage on the differential inputs does not go more positive than AV_{DD} + 30 mV or go more negative than AGND – 30 mV. The common-mode mode voltage applies to those inputs which form differential pairs (see Table VI).

[10]These numbers are guaranteed by design and/or characterization.

[11]The analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance depends on the selected gain.

[12]The analog input voltage range on the analog inputs is given here with respect to the voltage on the respective negative input of its differential or pseudo-differential pair (see Table V). The absolute voltage on the analog inputs should not go more positive than AV_{DD} + 30 mV or go more negative than AGND – 30 mV.

[13]V_{REF} = REF IN(+) – REF IN(–).

[14]Sample tested at +25°C to ensure compliance.

[15]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[16]These calibration and span limits apply provided the absolute voltage on the analog inputs does not exceed AV_{DD} + 30 mV or go more negative than AGND – 30 mV. The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

[17]For higher gains (≥8) at $f_{CLK\,IN}$ = 2.4576 MHz, the BST bit of the Filter High Register must be set to 1. For other conditions, it can be set to 0.

[18]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 5, 10, 25 or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 6, 10, 30 or 60 Hz.

[19]PSRR depends on gain: Gain of 1: 70 dB typ; Gain of 2: 75 dB typ; Gain of 4: 80 dB typ; Gains of 8 to 128: 85 dB typ.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1, 2] (DV_{DD} = +3 V to +5 V, ± 5%; AV_{DD} = +3 V or +5 V, ± 5%; AGND = DGND = 0 V; f_{CLKIN} = 2.5 MHz; Input Logic 0 = 0 V, Logic 1 = DV_{DD} unless otherwise noted.)

Parameter	Limit at T_{MIN}, T_{MAX} (A, S Versions)	Units	Conditions/Comments
f_{CLKIN}[3, 4]	400	kHz min	Master Clock Frequency: Crystal Oscillator or Externally Supplied
	2.5	MHz max	For Specified Performance
$t_{CLK\ IN\ LO}$	0.4 × $t_{CLK\ IN}$	ns min	Master Clock Input Low Time. $t_{CLK\ IN}$ = 1/$f_{CLK\ IN}$
$t_{CLK\ IN\ HI}$	0.4 × $t_{CLK\ IN}$	ns min	Master Clock Input High Time
t_r[5]	50	ns max	Digital Output Rise Time. Typically 20 ns
t_f[5]	50	ns max	Digital Output Fall Time. Typically 20 ns
t_{DRDY}	500 × $t_{CLK\ IN}$	ns nom	$\overline{DRDY}$ High Time
t_1	1000	ns min	$\overline{SYNC}$ Pulse Width
t_2	1000	ns min	$\overline{RESET}$ Pulse Width
Read Operation			
t_3	0	ns min	$\overline{DRDY}$ to $\overline{CS}$ Setup Time
t_4	20	ns min	$\overline{CS}$ Falling Edge to SCLK Falling Edge (POL = 1) or SCLK Rising Edge (POL = 0) Setup Time
t_5[6]	0	ns min	SCLK Active Edge to Data Valid Delay[7]
	20	ns max	DV_{DD} = +5 V
	40	ns max	DV_{DD} = +3 V
t_6	200	ns min	SCLK High Pulse Width
t_7	200	ns min	SCLK Low Pulse Width
t_8	20	ns min	$\overline{CS}$ Rising Edge to SCLK Rising Edge (POL = 1) or SCLK Falling Edge (POL = 0) Hold Time
t_9[8]	10	ns min	Bus Relinquish Time after SCLK Rising Edge (POL = 1) or
	50	ns max	SCLK Falling Edge (POL = 0). DV_{DD} = +5 V
	100	ns max	SCLK Falling Edge (POL = 0). DV_{DD} = +3 V
t_{10}	50	ns max	SCLK Rising Edge (POL = 1) or SCLK Falling Edge (POL = 0) to $\overline{DRDY}$ High[9]
Write Operation			
t_{11}	20	ns min	$\overline{CS}$ Falling Edge to SCLK Falling Edge (POL = 1) or SCLK Rising Edge (POL = 0) Setup Time
t_{12}	30	ns min	Data Valid to SCLK Active Edge Setup Time[6]
t_{13}	20	ns min	Data Valid to SCLK Active Edge Hold Time[6]
t_{14}	200	ns min	SCLK High Pulse Width
t_{15}	200	ns min	SCLK Low Pulse Width
t_{16}	20	ns min	$\overline{CS}$ Rising Edge to SCLK Rising Edge (POL = 1) or SCLK Falling Edge (POL = 0) Hold Time

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of DV_{DD}) and timed from a voltage level of 1.6 V.

[2]See Figures 2 and 3.

[3]CLKIN Duty Cycle range is 45% to 55%. CLKIN must be supplied whenever the AD7714 is not in standby mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7714 is production tested with f_{CLKIN} at 2.5 MHz (1 MHz for some I_{DD} tests). It is guaranteed by characterization to operate at 400 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross the V_{OL} or V_{OH} limits.

[7]SCLK active edge is falling edge of SCLK with POL = 1; SCLK active edge is rising edge of SCLK with POL = 0.

[8]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 100 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.

[9]$\overline{DRDY}$ returns high after the first read from the device after an output update. The same data can be read again, if required, while $\overline{DRDY}$ is high although care should be taken that subsequent reads do not occur close to the next output update.

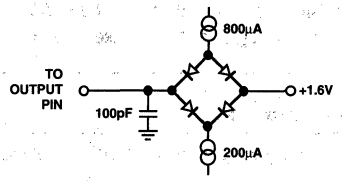

Figure 1. Load Circuit for Access Time and Bus Relinquish Time

ORDERING GUIDE

Model	AV_{DD} Supply	Temperature Range	Package Option*
AD7714AN-5	5 V	–40°C to +85°C	N-24
AD7714AR-5	5 V	–40°C to +85°C	R-24
AD7714ARS-5	5 V	–40°C to +85°C	RS-28
AD7714SQ-5	5 V	–55°C to +125°C	Q-24
AD7714AN-3	3 V	–40°C to +85°C	N-24

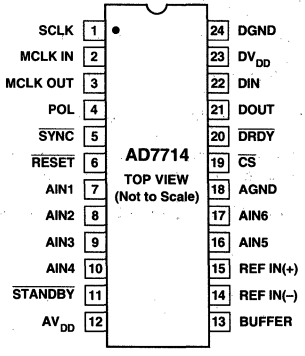
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

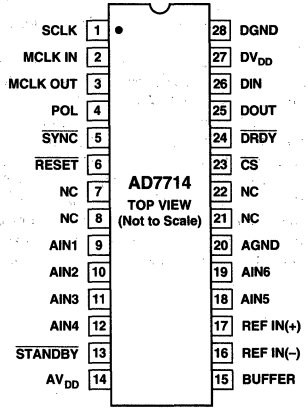
ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7714 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS

DIP & SOIC



SSOP



NC = NO CONNECT

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PIN FUNCTION DESCRIPTION

DIP/SOIC PIN NUMBERS

Pin No.	Mnemonic	Function
1	SCLK	Serial Clock. Logic Input. An external serial clock is applied to this input to access serial data from the AD7714. This serial clock can be a continuous clock with all data transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7714 in smaller batches of data.
2	MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS-compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally either 2.5 MHz or 1 MHz.
3	MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT.
4	POL	Clock Polarity. Logic Input. With this input low, the first transition of the serial clock in a data transfer operation is from a low to a high. In microcontroller applications this means that the serial clock should idle low between data transfers. With this input high, the first transition of the serial clock in a data transfer operation is from a high to a low. In microcontroller applications, this means that the serial clock should idle high between data transfers.
5	$\overline{\text{SYNC}}$	Logic Input which allows for synchronization of the digital filters and analog modulators when using a number of AD7714s. While $\overline{\text{SYNC}}$ is low, the nodes of the digital filter, the filter control logic and the calibration control logic are reset and the analog modulator is also held in its reset state.
6	$\overline{\text{RESET}}$	Logic Input. Active low input which resets the control logic, interface logic, digital filter and analog modulator of the part to power-on status.
7	AIN1	Analog Input Channel 1. Programmable-gain analog input which can be used as a pseudo-differential input when used with AIN6 or as the positive input of a differential analog input pair when used with AIN2 (see Communications Register section).
8	AIN2	Analog Input Channel 2. Programmable-gain analog input which can be used as a pseudo-differential input when used with AIN6 or as the negative input of a differential analog input pair when used with AIN1 (see Communications Register section).
9	AIN3	Analog Input Channel 3. Programmable-gain analog input which can be used as a pseudo-differential input when used with AIN6 or as the positive input of a differential analog input pair when used with AIN4 (see Communications Register section).
10	AIN4	Analog Input Channel 4. Programmable-gain analog input which can be used as a pseudo-differential input when used with AIN6 or as the negative input of a differential analog input pair when used with AIN3 (see Communications Register section).
11	$\overline{\text{STANDBY}}$	Logic Input. Taking this pin low shuts down the analog and digital circuitry, reducing power consumption to typically 50 μW.
12	AV_{DD}	Analog Positive Supply Voltage, +3 V nominal (AD7714-3) or +5 V nominal (AD7714-5).
13	BUFFER	Buffer Option Select. Logic Input. With this input low, the on-chip buffer on the analog input (after the multiplexer and before the analog modulator) is shorted out. With the buffer shorted out the current flowing in the AV_{DD} line is reduced to 300 μA ($f_{CLK\ IN}$ = 1 MHz) or 500 μA ($f_{CLK\ IN}$ = 2.5 MHz). With this input high, the on-chip buffer is in series with the analog input allowing the inputs to handle higher source impedances.
14	REF IN(–)	Reference Input. Negative input of the differential reference input to the AD7714. The REF IN(–) can lie anywhere between AV_{DD} and AGND provided REF IN(+) is greater than REF IN(–).
15	REF IN(+)	Reference Input. Positive input of the differential reference input to the AD7714. The reference input is differential with the provision that REF IN(+) must be greater than REF IN(–). REF IN(+) can lie anywhere between AV_{DD} and AGND.
16	AIN5	Analog Input Channel 5. Programmable-gain analog input which is the positive input of a differential analog input pair when used with AIN6 (see Communications Register section).
17	AIN6	Analog Input Channel 6. Reference point for AIN1 through AIN4 in pseudo-differential mode or as the negative input of a differential analog input pair when used with AIN5 (see Communications Register section).
18	AGND	Ground reference point for analog circuitry.

Pin No.	Mnemonic	Function
19	$\overline{CS}$	Chip Select. Active low Logic Input used to select the AD7714. With this input hard-wired low, the AD7714 can operate in its three-wire interface mode with SCLK, DIN and DOUT used to interface to the device. $\overline{CS}$ can be used to select the device in systems with more than one device on the serial bus or as a frame synchronization signal in communicating with the AD7714.
20	$\overline{DRDY}$	Logic output. A logic low on this output indicates that a new output word is available from the AD7714 data register. The $\overline{DRDY}$ pin will return high upon completion of a read operation of a full output word. If no data read has taken place, after an output update, the $\overline{DRDY}$ line will return high for 500 × $t_{CLK\ IN}$ cycles prior to he next output update. This gives an indication of when a read operation should not be attempted to avoid reading from the data register as it is being updated. $\overline{DRDY}$ is also used to indicate when the AD7714 has completed its on-chip calibration sequence.
21	DOUT	Serial Data Output with serial data being read from the output shift register on the part. This output shift register can contain information from the calibration registers, mode register, communications register, filter selection registers or data register depending on the register selection bits of the Communications Register.
22	DIN	Serial Data Input with serial data being written to the input shift register on the part. Data from this input shift register is transferred to the calibration registers, mode register, communications register or filter selection registers depending on the register selection bits of the Communications Register.
23	DV_{DD}	Digital Supply Voltage, +3 V or +5 V nominal.
24	DGND	Ground reference point for digital circuitry.

TERMINOLOGY*

INTEGRAL NONLINEARITY

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero-scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and Full-Scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

POSITIVE FULL-SCALE ERROR

Positive Full-Scale Error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal AIN(+) voltage (AIN(–) + V_{REF}/GAIN – 3/2 LSBs). It applies to both unipolar and bipolar analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar Offset Error is the deviation of the first code transition from the ideal AIN(+) voltage (AIN(–) + 0.5 LSB) when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal AIN(+) voltage (AIN(–) – 0.5 LSB) when operating in the bipolar mode.

GAIN ERROR

This is a measure of the span error of the ADC. It includes full-scale errors but not zero-scale errors. For unipolar input ranges it is defined as (full-scale error–unipolar offset error) while for bipolar input ranges it is defined as (full-scale error–bipolar zero error).

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal AIN(+) voltage (AIN(–) – V_{REF}/GAIN + 0.5 LSB), when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive Full-Scale Overrange is the amount of overhead available to handle input voltages on AIN(+) input greater than AIN(–) + V_{REF}/GAIN (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages on AIN(+) below AIN(–) – V_{REF}/GAIN without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode provided that AIN(+) is greater than AIN(–) and greater than AGND – 30 mV.

OFFSET CALIBRATION RANGE

In the system calibration modes, the AD7714 calibrates its offset with respect to the analog input. The Offset Calibration Range specification defines the range of voltages that the AD7714 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7714 can accept in the system calibration mode and still calibrate full-scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7714's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full-scale that the AD7714 can accept and still calibrate gain accurately.

*AIN(–) refers to the negative input of the differential input pairs or to AIN6 when referring to the pseudo-differential input configurations

AD7714-5 Output Noise

Table I shows the output rms noise and effective resolution for some typical notch and –3 dB frequencies for the AD7714-5 with $f_{CLK\,IN}$ = 2.4576 MHz while Table II gives the information for $f_{CLK\,IN}$ = 1 MHz. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V and with BUFFER = 0. These numbers are typical and are generated at an analog input voltage of 0 V. The numbers in brackets in each table are for the effective resolution of the part (rounded to the nearest 0.5 LSB). The effective resolution of the device is defined as the ratio of the output rms noise to the input full-scale (i.e., $2 \times V_{REF}$/GAIN). It should be noted that it is not calculated using peak-to-peak output noise numbers. Peak-to-peak noise numbers can be up to 6.6 times the rms numbers while effective resolution numbers based on peak-to-peak noise can be 2.5 bits below the effective resolution based on rms noise as quoted in the tables.

The output noise from the part comes from two sources. The first is the electrical noise in the semiconductor devices used in the implementation of the modulator (device noise). Secondly, when the analog input signal is converted into the digital domain, quantization noise is added. The device noise is at a low level and is largely independent of frequency. The quantization noise starts at an even lower level but rises rapidly with increasing frequency to become the dominant noise source. Consequently, lower filter notch settings (below 100 Hz approximately for $f_{CLK\,IN}$ = 2.4576 MHz and below 40 Hz approximately for $f_{CLK\,IN}$ = 1 MHz) tend to be device noise dominated while higher notch settings are dominated by quantization noise. Changing the filter notch and cutoff frequency in the quantization-noise dominated region results in a more dramatic improvement in noise performance than it does in the device-noise dominated region as shown in Tables I and II. Furthermore, quantization noise is added after the PGA, so effective resolution is largely independent of gain for the higher filter notch frequencies. Meanwhile, device noise is added in the PGA and, therefore, effective resolution reduces at high gains for lower notch frequencies. Additionally, in the device-noise dominated region, the output noise is largely independent of reference voltage while in the quantization-noise dominated region, the noise is proportional to the value of the reference. Noise numbers in the device noise dominated region will be higher than those in the Table I for BUFFER = 1 (at a gain of 128, 10 Hz notch rms noise will be 500 nV). It is possible to do post-filtering on the device to improve the output data rate for a given –3 dB frequency and also to further reduce the output noise.

At the lower filter notch settings (below 60 Hz for $f_{CLK\,IN}$ = 2.4576 MHz and below 25 Hz for $f_{CLK\,IN}$ = 1 MHz), the no missing codes performance of the device is at the 24-bit level. At the higher settings, more codes will be missed until at 1 kHz notch setting for $f_{CLK\,IN}$ = 2.4576 MHz (400 Hz for $f_{CLK\,IN}$ = 1 MHz), no missing codes performance is only guaranteed to the 12-bit level.

Table I. Output Noise/Effective Resolution vs. Gain and First Notch Frequency for $f_{CLK\,IN}$ = 2.4576 MHz, BUFFER = 0

AD7714-3 Output Noise

Table III shows the output rms noise and effective resolution for some typical notch and –3 dB frequencies for the AD7714-3 with $f_{CLK\ IN}$ = 2.4576 MHz while Table IV gives the information for $f_{CLK\ IN}$ = 1 MHz. The numbers given are for the bipolar input ranges with a V_{REF} of +1.25 V and BUFFER = 0. These numbers are typical and are generated at an analog input voltage of 0 V. The numbers in brackets in each table are for the effective resolution of the part (rounded to the nearest 0.5 LSB). The effective resolution of the device is defined as the ratio of the output rms noise to the input full-scale (i.e., $2 \times V_{REF}/GAIN$). It should be noted that it is not calculated using peak-to-peak output noise numbers. Peak-to-peak noise numbers can be up to 6.6 times the rms numbers while effective resolution numbers based on peak-to-peak noise can be 2.5 bits below the effective resolution based on rms noise as quoted in the tables.

The output noise from the part comes from two sources. The first is the electrical noise in the semiconductor devices used in the implementation of the modulator (device noise). Secondly, when the analog input signal is converted into the digital domain, quantization noise is added. The device noise is at a low level and is largely independent of frequency. The quantization noise starts at an even lower level but rises rapidly with increasing frequency to become the dominant noise source. Consequently, lower filter notch settings (below 100 Hz approximately for $f_{CLK\ IN}$ = 2.4576 MHz and below 40 Hz approximately for $f_{CLK\ IN}$ = 1 MHz) tend to be device noise dominated while higher notch settings are dominated by quantization noise. Changing the filter notch and cutoff frequency in the quantization noise dominated region results in a more dramatic improvement in noise performance than it does in the device-noise dominated region as shown in Tables III and IV. Furthermore, quantization noise is added after the PGA, so effective resolution is largely independent of gain for the higher filter notch frequencies. Meanwhile, device noise is added in the PGA and, therefore, effective resolution suffers a little at high gains for lower notch frequencies. Additionally, in the device-noise dominated region, the output noise is largely independent of reference voltage while in the quantization-noise dominated region, the noise is proportional to the value of the reference. Noise numbers in the device noise dominated region will be higher than those in the Table III for BUFFER = 1 (at a gain of 128, 10 Hz notch rms noise will be 500 nV). It is possible to do post-filtering on the device to improve the output data rate for a given –3 dB frequency and also to further reduce the output noise (see Digital Filtering section).

At the lower filter notch settings (below 60 Hz for $f_{CLK\ IN}$ = 2.4576 MHz and below 25 Hz for $f_{CLK\ IN}$ = 1 MHz), the no missing codes performance of the device is at the 24-bit level. At the higher settings, more codes will be missed until at 1 kHz notch setting for $f_{CLK\ IN}$ = 2.4576 MHz (400 Hz for $f_{CLK\ IN}$ = 1 MHz), no missing codes performance is only guaranteed to the 12-bit level.

On-Chip Registers

The AD7714 contains eight on-chip registers which can be accessed via the serial port of the part. The first of these is a Communications Register which controls the channel selection, decides whether the next operation is a read or write operation and also decides which register the next read or write operation accesses. The $\overline{DRDY}$ status is also available by reading from the Communications Register. The second register is a Mode Register which determines calibration mode and gain setting. The third register is labelled the Filter High Register and this determines the word length, bipolar/unipolar operation and contains the upper 4 bits of the filter selection word. The fourth register is labelled the Filter Low Register and contains the lower 8 bits of the filter selection word. The fifth register is a Test Register which is accessed when testing the device. The sixth register is the Data Register from which the output data from the part is accessed. The final two registers are calibration registers; one is the Calibration Zero-Scale Register and the other is the Calibration Full-Scale Register. The registers are discussed in more detail in the following sections.

Communications Register (RS2–RS0 = 0, 0, 0)

The Communications Register is an eight bit register from which data can either be read or to which data can be written. On power-up or after a $\overline{RESET}$, the AD7714 is waiting for a write operation to the Communications Register. This is the default state of the interface, and in situations where the interface sequence is lost, if enough writes to the device (at least four bytes) take place with DIN high, the AD7714 returns to its default state. Table V outlines the bit designations for the Communications Register.

Table V. Communications Register

0/$\overline{DRDY}$	RS2	RS1	RS0	R/$\overline{W}$	CH2	CH1	CH0

0/$\overline{DRDY}$

For a read operation, this bit provides the status of the $\overline{DRDY}$ flag from the part. The status of this bit is the same as the $\overline{DRDY}$ output pin. For a write operation, a 0 must be written to this bit so that the write operation will be recognized by the register. If a 1 is written to this bit, the part will not clock on to subsequent bits in the register.

RS2–RS0

Register Selection Bits. RS2 is the MSB of the three selection bits. The three bits select to which one of eight on-chip registers the next read or write operation takes place as follows:

RS2	RS1	RS0	Register	Register Size
0	0	0	Communications Register	8 Bits
0	0	1	Mode Register	8 Bits
0	1	0	Filter High Register	8 Bits
0	1	1	Filter Low Register	8 Bits
1	0	0	Test Register	8 Bits
1	0	1	Data Register	16 Bits or 24 Bits
1	1	0	Calibration Zero-Scale Register	24 Bits
1	1	1	Calibration Full-Scale Register	24 Bits

R/$\overline{W}$

Read/Write Select. This bit selects whether the next operation is a read or write operation to the selected register. A 0 indicates a write cycle for the next operation to the appropriate register, while a 1 indicates a read operation from the appropriate register.

CH2–CH0

Channel Select. These three bits select a channel for either conversion or for access to calibration coefficients as outlined in Table VI. There are three pairs of calibration registers on the part with some of the input channel combinations sharing calibration registers. With CH2, CH1 and CH0 at a logic 1, the part internally looks at shorted AIN6 inputs. This can be used as a test method to evaluate the noise performance of the part. The power-on or RESET status of these bits is 1, 0, 0 selecting the differential pair AIN1 and AIN2.

Table VI. Channel Selection

CH2	CH1	CH0	AIN(+)	AIN(–)	Type	Calibration Register Pair
0	0	0	AIN1	AIN6	Pseudo Differential	Register Pair 0
0	0	1	AIN2	AIN6	Pseudo Differential	Register Pair 1
0	1	0	AIN3	AIN6	Pseudo Differential	Register Pair 2
0	1	1	AIN4	AIN6	Pseudo Differential	Register Pair 2
1	0	0	AIN1	AIN2	Fully Differential	Register Pair 0
1	0	1	AIN3	AIN4	Fully Differential	Register Pair 1
1	1	0	AIN5	AIN6	Fully Differential	Register Pair 2
1	1	1	AIN6	AIN6	Test Mode	Register Pair 2

Mode Register (RS2-RS0 = 0, 0, 1); Power On/Reset Status: 00 Hex

The Mode Register is an eight bit register from which data can either be read or to which data can be written. Table VII outlines the bit designations for the Mode Register.

Table VII. Mode Register

MD2	MD1	MD0	G2	G1	G0	BO	FSYNC

MD2	MD1	MD0	Operating Mode
0	0	0	Normal Mode; this is the normal mode of operation of the device whereby the device is performing normal conversions. This is the default condition of these bits after Power-On or RESET.
0	0	1	Self-Calibration; this activates self-calibration on the channel selected by CH2, CH1 and CH0 of the Communications Register. This is a one step calibration sequence and when complete the part returns to Normal Mode. The $\overline{DRDY}$ output or bit indicates when this self-calibration is complete and when a new valid word is available in the data register. For this calibration type, the zero-scale calibration is done internally on shorted (zeroed) inputs and the full-scale calibration is done internally on V_{REF}.
0	1	0	Zero-Scale System Calibration; this activates zero-scale system calibration on the channel selected by CH2, CH1 and CH0 of the Communications Register. Calibration is performed on the analog input voltage provided at the analog input during this calibration sequence. The $\overline{DRDY}$ output or bit indicates when this zero-scale calibration is complete and the part returns to Normal Mode.
0	1	1	Full-Scale System Calibration; this activates full-scale system calibration on the selected input channel. Calibration is performed on the analog input voltage provided at the analog input during this calibration sequence. Once again, $\overline{DRDY}$ indicates when this full-scale calibration is complete. When this calibration is complete, the part returns to Normal Mode.
1	0	0	System-Offset Calibration; this activates system-offset calibration on the channel selected by CH2, CH1 and CH0 of the Communications Register. This is a one step calibration sequence and when complete the part returns to Normal Mode with $\overline{DRDY}$ indicating when this system offset calibration is complete. For this calibration type, the zero-scale calibration is done on the selected input channel and the full-scale calibration is done internally on V_{REF}.
1	0	1	Background Calibration; this activates background calibration on the channel selected by CH2, CH1 and CH0 of the Communications Register. If the background calibration mode is on, the AD7714 provides continuous self-calibration of the shorted (zeroed) inputs. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the offset of the device when there is a change in the ambient temperature or supplies. In this mode, the shorted (zeroed) inputs, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are automatically updated. Because the background calibration does not perform full-scale calibrations, a full-scale self-calibration should be performed before placing the part in background calibration mode.
1	1	0	Zero-Scale Self-Calibration; this activates zero-scale self-calibration on the channel selected by CH2, CH1 and CH0 of the Communications Register. This zero-scale calibration is done internally on shorted (zeroed) inputs. This is a one step calibration sequence and when complete the part returns to Normal Mode. The $\overline{DRDY}$ output or bit indicates when this zero-scale self-calibration is complete.
1	1	1	Full-Scale Self-Calibration; this activates full-scale self-calibration on the channel selected by CH2, CH1 and CH0 of the Communications Register. This full-scale calibration is done internally on V_{REF}. This is a one step calibration sequence and when complete the part returns to Normal Mode. The $\overline{DRDY}$ output indicates when this full-scale self-calibration is complete.
G2	G1	G0	Gain Setting
0	0	0	1
0	0	1	2
0	1	0	4
0	1	1	8
1	0	0	16
1	0	1	32
1	1	0	64
1	1	1	128
BO			Burn Out Current. A 0 in this bit turns off the on-chip burn out currents. This is the default (Power-On or RESET) status of this bit. A 1 in this bit activates the burn out currents.
FSYNC			Filter Synchronization. When this bit is high, the nodes of the digital filter, the filter control logic and the calibration control logic are reset, and the analog modulator is also held in its reset state. When this bit goes low, valid data is available in 3 × 1/(output update rate), i.e., the settling time of the filter.

Filter Registers. Power On/Reset Status: Filter High Register: 01 Hex. Filter Low Register: 40 Hex
There are two 8-bit Filter Registers on the AD7714 from which data can either be read or to which data can be written. Tables VIII and IX outline the bit designations for the Filter Registers.

Table VIII. Filter High Register (RS2–RS0 = 0, 1, 0)

$\overline{B}$/U	WL	BST	0	FS11	FS10	FS9	FS8

Table IX. Filter Low Register (RS2–RS0 = 0, 1, 1)

FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0

$\overline{B}$/U	Bipolar/Unipolar Operation. A 0 in this bit selects Bipolar Operation. This is the default (Power-On or $\overline{RESET}$) status of this bit. A 1 in this bit selects unipolar operation.
WL	Word Length. A 0 in this bit selects 16-bit word length when reading from the data register (i.e., $\overline{DRDY}$ returns high after 16 serial clock cycles). This is the default (Power-On or RESET) status of this bit. A 1 in this bit selects 24-bit word length.
BST	Current Boost. A 0 in this bit reduces the current taken by the analog front-end. When the part is operated with $f_{CLK\ IN}$ = 1 MHz, this bit should be 0 to reduce the current drawn from AV_{DD}. When the AD7714 is operated from $f_{CLK\ IN}$ = 2.4576 MHz with gains of 8 to 128, this bit needs to be 1 to ensure correct operation of the device. The Power-On or $\overline{RESET}$ status of this bit is 0.
0	To ensure correct operation of the part, a 0 must be written to this bit.
FS11–FS0	Filter Selection. The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$) filter response. The 12-bits of data programmed into these bits determine the filter cut-off frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device. The first notch of the filter occurs at a frequency determined by the relationship: *filter first notch frequency = ($f_{CLK\ IN}$/128)/code* where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 4,000. With the nominal $f_{CLK\ IN}$ of 2.4576 MHz, this results in a first notch frequency range from 4.8 Hz to 1.01 kHz. To ensure correct operation of the AD7714, the value of the code loaded to these bits must be within this range. Failure to do this will result in unspecified operation of the device. Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I through IV show the effect of the filter notch frequency and gain on the effective resolution of the AD7714. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 50 Hz, then a new word is available at a 50 Hz rate or every 20 ms. If the first notch is at 1 kHz, a new word is available every 1 ms. The settling-time of the filter to a full-scale step input change is worst case 4 × 1/(output data rate). For example, with the first filter notch at 50 Hz, the settling time of the filter to a full-scale step input change is 80 ms max. If the first notch is at 1 kHz, the settling time of the filter to a full-scale input step is 4 ms max. This settling-time can be reduced to 3 × 1/(output data rate) by synchronizing the step input change to a reset of the digital filter. In other words, if the step input takes place with the $\overline{SYNC}$ input low or the FSYNC bit high, the settling-time time will be 3 × 1/(output data rate) from when $\overline{SYNC}$ returns high or FSYNC returns low. If a change of channel takes place, the settling-time is 3 × 1/(output data rate) regardless of the $\overline{SYNC}$ or FSYNC status as the part issues an internal SYNC command when requested to change channels. The –3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter –3 dB frequency = 0.262 × first notch frequency.

Test Register (RS2–RS0 = 1, 0 , 0)
The part contains a Test Register which is used in testing the device. The user is advised not to change the status of any of the bits in this register from the default (Power-On or RESET) status of all 0s as the part will be placed in one of its test modes and will not operate correctly. If the part enters one of its test modes, exercising $\overline{RESET}$ will exit the part from the mode.

Data Register (RS2–RS0 = 1, 0, 1)
The Data Register on the part is a read-only register which contains the most up-to-date conversion result from the AD7714. The register can be programmed to be either 16 bits or 24 bits wide, determined by the status of the WL bit of the Mode Register. If an attempt is made to write to this register, the 16 or 24 bits of data will not actually be written to any location of the AD7714.

Calibration Zero-Scale Register (RS2–RS0 = 1, 1, 0)
The AD7714 contains 3 zero-scale calibration registers, labelled Register 0 to Register 2. Each of these registers is a 24-bit read/write register and 24 bits must be written; otherwise no data will be transferred to the register. The register is used in conjunction with the associated full-scale calibration register to form a register pair. These register pairs are associated with input channel pairs as outlined in Table VI.

There is a possibility that after accessing the calibration registers (either read or write operation), the first output data read from the part contain incorrect data. In addition, a read or write operation to the calibration register should not be attempted while a calibration is in progress. These eventualities can be avoided by taking either the $\overline{\text{SYNC}}$ input low or the FSYNC bit of the Mode Register high before the calibration register operation and taking them either high or low respectively after the operation is complete.

Calibration Full-Scale Register (RS2–RS0 = 1, 1, 1)
The AD7714 contains 3 full-scale calibration registers, labelled Register 0 to Register 2. Each of these registers is a 24-bit read/write register and 24 bits must be written, otherwise no data will be transferred to the register. The register is used in conjunction with the associated zero scale calibration register to form a register pair. These register pairs are associated with input channel pairs as outlined in Table VI.

There is a possibility that after accessing the calibration registers (either read or write operation), the first output data read from the part will contain incorrect data. In addition, a read or write operation to the calibration register should not be attempted while a calibration is in progress. These eventualities can be avoided by taking either the $\overline{\text{SYNC}}$ input low or the FSYNC bit of the Mode Register high before the calibration register operation and taking them either high or low respectively after the operation is complete.

CIRCUIT DESCRIPTION

The AD7714 is a sigma-delta A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those in weigh-scale, industrial control or process control applications. It contains a sigma-delta (or charge-balancing) ADC, a calibration microcontroller with on-chip static RAM, a clock oscillator, a digital filter and a bidirectional serial communications port. The part consumes only 500 μA of power supply current, making it ideal for battery-powered or loop-powered instruments. The part comes in two versions, the AD7714-5 which is specified for operation from a +5 V analog supply (AV_{DD}) and the AD7714-3 which is specified for operation from a +3 V analog supply. The AD7714-5 can be operated with a digital supply (DV_{DD}) voltage of +3 V or +5 V.

The part contains three programmable-gain fully differential analog input channels which can be reconfigured as five pseudo-differential inputs. The gain range on all channels is from 1 to 128 allowing the part to accept unipolar signals of between 0 mV to +20 mV and 0 V to +2.5 V or bipolar signals in the range from ±20 mV to ±2.5 V when the reference input voltage equals +2.5 V. With a reference voltage of +1.25 V, the input ranges are from 0 mV to +10 mV to 0 V to +1.25 V in unipolar mode and from ±10 mV to ±1.25 V in bipolar mode.

The input signal to the selected analog input channel is continuously sampled at a rate determined by the frequency of the master clock, MCLK IN, and the selected gain. A charge-balancing A/D converter (Sigma-Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. The programmable gain function on the analog input is also incorporated in this sigma delta modulator with the input sampling frequency being modified to give the higher gains. A $Sinc^3$ digital low-pass filter processes the output of the sigma-delta modulator and updates the output register at a rate determined by the first notch frequency of this filter. The output data can be read from the serial port randomly or periodically at any rate up to the output register update rate. The first notch of this digital filter (and hence its –3 dB frequency) can be programmed via the filter high and filter low registers. With a master clock frequency of 2.4576 MHz, the programmable range for this first notch frequency is from 4.8 Hz to 1.01 kHz giving a programmable range for the –3 dB frequency of 1.26 Hz to 265 Hz.

The basic connection diagram for the part is shown in Figure 2. This shows both the AV_{DD} and DV_{DD} pins of the AD7714 being driven from the analog +3 V or +5 V supply. Some applications will have AV_{DD} and DV_{DD} driven from separate supplies. In the connection diagram shown, the AD7714's analog inputs are configured as three fully differential inputs. The part is set up for unbuffered mode on the these analog inputs. An AD780, precision +2.5 V reference, provides the reference source for the part. On the digital side, the part is configured for three-wire operation with $\overline{\text{CS}}$ tied to DGND. A quartz crystal or ceramic resonator provides the master clock source for the part.

The AD7714 provides a number of calibration options which can be programmed via the MD2, MD1 and MD0 bits of the Mode Register. A calibration cycle may be initiated at any time by writing to these bits of the Mode Register. The part can perform self-calibration using the on-chip calibration microcontroller and SRAM to store calibration parameters. Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel using the system calibration mode. Another option is a background calibration mode where the part continuously performs internal zero-scale calibrations and updates the calibration coefficients. Using the part in this mode, the user does not have to worry

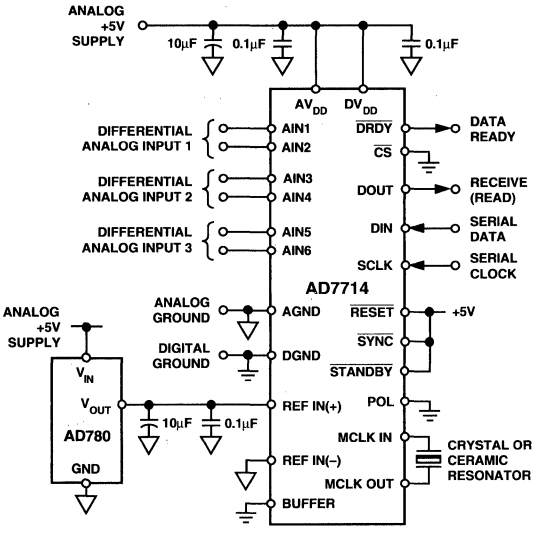

Figure 2. Basic Connection Diagram

about issuing periodic calibration commands to the device or ask the device to recalibrate when there is a change in the ambient temperature or power supply voltage. This automatic removal of offset errors is achieved at the expense of output update rate which is reduced by a factor of six. Using the part in background calibration mode automatically removes offset errors but not full-scale errors. A full-scale self-calibration should be performed before entering the background calibration mode. The residual gain drift in background calibration mode is 2 ppm/°C.

The AD7714 gives the user access to the on-chip calibration registers allowing the microprocessor to read the device's calibration coefficients and also to write its own calibration coefficients to the part from prestored values in E²PROM. This gives the microprocessor much greater control over the AD7714's calibration procedure. It also means that the user can verify that the device has performed its calibration correctly by comparing the coefficients after calibration with prestored values in E²PROM. Table X details the calibration options and sequences available on the AD7714. For the table, Sel Gain refers to the selected operating gain.

DIGITAL INTERFACE

The AD7714's serial interface consists of five signals, $\overline{CS}$, SCLK, DIN, DOUT and $\overline{DRDY}$. The DIN line is used for

Table X. Calibration Sequences

Calibration Type	MD2, MD1, MD0	Calibration Sequence	Duration
Self Calibration	0, 0, 1	Internal ZS Cal @ Sel Gain + Internal FS Cal @ Sel Gain	9 × 1/Output Rate
ZS System Calibration	0, 1, 0	ZS Cal on AIN @ Sel Gain	3 × 1/Output Rate
FS System Calibration	0, 1, 1	FS Cal on AIN @ Sel Gain	3 × 1/Output Rate
System-Offset Calibration	1, 0, 0	ZS Cal on AIN @ Sel Gain + Internal FS Cal @ Sel Gain	9 × 1/Output Rate
Background Calibration	1, 0, 1	Internal ZS Cal @ Sel Gain	6 × 1/Output Rate
ZS Self Calibration	1, 1, 0	Internal ZS Cal @ Sel Gain	3 × 1/Output Rate
FS Self Calibration	1, 1, 1	Internal FS Cal @ Sel Gain	3 × 1/Output Rate

transferring data into the on-chip registers while the DOUT line is used for accessing data from the on-chip registers. SCLK is the serial clock input for the device and all data transfers (either on DIN or DOUT) take place with respect to this SCLK signal. The $\overline{DRDY}$ line is used as a status signal to indicate when data is ready to be read from the AD7714's data register. $\overline{DRDY}$ goes low when a new data word is available in the output register. It is reset high when a read operation from the data register is complete. It also goes high prior to the updating of the output register to indicate when not to read from the device to ensure that a data read is not attempted while the register is being updated. $\overline{CS}$ is used to select the device. It can be used to decode the AD7714 in systems where a number of parts are connected to the serial bus.

The AD7714 serial interface can operate in three-wire mode by tying the $\overline{CS}$ input low. In this case, the SCLK, DIN and DOUT lines are used to communicate with the AD7714 and the status of $\overline{DRDY}$ can be obtained by interrogating the MSB of the Communications Register.

Figures 3 and 4 show timing diagrams for interfacing to the AD7714 with $\overline{CS}$ used to decode the part. Figure 3 is for a read operation from the AD7714's output shift register while Figure 4 shows a write operation to the input shift register. Both diagrams are for the POL input at a logic high; for operation with the POL input at a logic high simply invert the SCLK waveform shown in the diagrams. It is possible to read the same data twice from the output register even though the $\overline{DRDY}$ line returns high after the first read operation. Care must be taken, however, to ensure that the read operations have been completed before the next output update is about to take place.

The serial interface can be reset by exercising the $\overline{RESET}$ input on the part. It can also be reset by writing a series of 1s on the DIN input. If a logic 1 is written to the AD7714 DIN line for at least 32 serial clock cycles, the serial interface is reset. This ensures that in three-wire systems that if the interface gets lost either via a software error or by some glitch in the system, it can be reset back into a known state. This known state (which is also where the interface returns to after a $\overline{RESET}$) is that the part is expecting a write operation to the Communications Register.

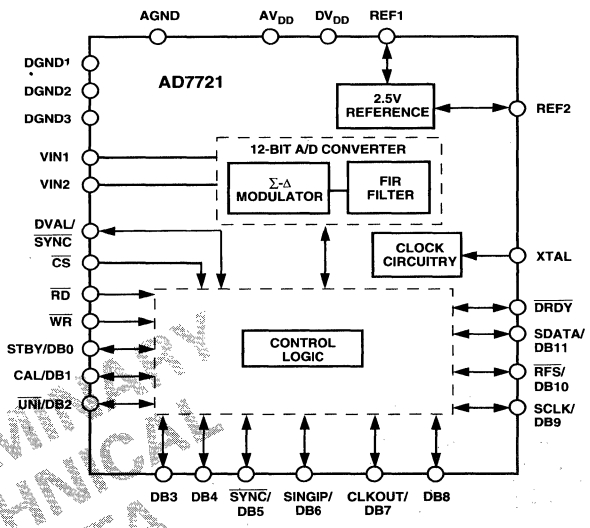
FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7721 is a complete low power, 12-bit, sigma-delta ADC. The part operates from a +5 V supply and accepts a differential input of 0 V to 2.5 V or ±1.25 V. The analog input is continuously sampled by an analog modulator at a 30 MHz rate eliminating the need for external sample-and-hold circuitry. The modulator output is processed by two finite impulse response (FIR) digital filters in series. The on-chip filtering reduces the external antialias requirements to first order in most cases. Settling-time for a step input is 98.74 µs while the group delay for the filter is 49.37 µs.

The AD7721 provides 12-bit performance for input bandwidths up to 210 kHz. The part provides data at an output word rate of 468.75 kHz. The sample rate, filter corner frequency and output word rate are set by an external clock or crystal that is nominally set to 15 MHz.

Use of a single bit DAC in the modulator guarantees excellent linearity and dc accuracy. Endpoint accuracy is ensured by on-chip calibration of offset and gain. This calibration procedure minimizes the part's zero-scale and full-scale errors.

The output data is accessed from the output register through a flexible serial port or a parallel port. This offers easy, high speed interfacing to modern microcontrollers and digital signal processors. The serial interface operates in external clocking (slave) mode. In this mode, an external serial clock and framing pulse must be provided to access the data from the output register.

The part provides an on-chip, accurate 2.5 V reference. A REFIN/REFOUT function is provided that allows either this internal reference or an external system reference to be used as the reference source for the part.

CMOS construction ensures low power dissipation while a power-down mode, initiated by the STBY pin, reduces the idle power consumption to only 100 µW.

V_{OL}, Output Low Voltage	0.4	0.4	V max	$\lvert I_{OUT} \rvert \le 1.6$ mA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Parameter	A Version	S Version	Units	Test Conditions/Comments
POWER SUPPLIES				
AV_{DD}	4.75/5.25	4.75/5.25	V min/V max	
DV_{DD}	4.75/5.25	4.75/5.25	V min/V max	
I_{DD} (Total from AV_{DD}, DV_{DD})	70	80	mA max	
Power Consumption	350	400	mW max	STBY = 0 V
Power Consumption	100	100	μW max	STBY = +5 V

NOTES
[1]Operating temperature range is as follows: A Version: –40°C to +85°C; S Version: –55°C to +125°C.
[2]Applies after calibration at temperature of interest.
[3]Full-scale error applies to both positive and negative full-scale error. It excludes reference error. The ADC gain is calibrated w.r.t. the voltage on the REF2 pin.
Specifications subject to change without notice.

TIMING CHARACTERISTICS[1] (AV_{DD} = +5 V ± 5%; DV_{DD} = +5 V ± 5%; AGND = DGND = 0 V, $f_{CLK\ IN}$ = 15 MHz, REFIN = +2.5 V)

NOTES
[1]t_7 and t_{14} are measured with the load circuit below and defined as the time required for an output to cross 0.4 V or 2 V.
[2]t_9 and t_{15} are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit shown below. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the time quoted in the Timing Characteristics is the true bus relinquish time of the part and, as such, is independent of external bus loading capacitance.

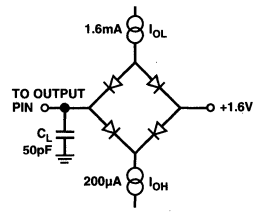

Figure 1. Load Circuit for Access Time and Bus Relinquish Time

PIN FUNCTION DESCRIPTION

Mnemonic	Function
AV_{DD}	Analog Positive Supply Voltage, +5 V ± 5%.
AGND	Ground reference point for analog circuitry.
DV_{DD}	Digital Supply Voltage, +5 V ± 5%.
DGND	Ground reference point for digital circuitry.
VIN1 VIN2	Analog Input. In unipolar operation, the analog input range on VIN1 is VIN2 to (VIN2 + V_{REF}); for diffxerential (bipolar) operation, the analog input range on VIN1 is (VIN2 ± V_{REF}/2). Alternatively, VIN2 can be connected to the internal reference in bipolar mode to give a single-ended input on VIN1 of (VREF ± VREF/2). VIN2 can be connected to the internal reference on chip by taking SINGIP high in the serial mode or writing to bit SINGIP in the parallel mode. The absolute analog input range must lie between 0 and AV_{DD}. The analog input is continuously sampled and processed by the analog modulator.
REF1 REF2	Reference Pins. The AD7721 can operate with the on-board reference which has a nominal value of 2.5 V. Alternatively, an external reference can be used. There are three modes of operation: 1. Using the internal reference. REF2 is used as the REFOUT. A 10 nF capacitor is required on REF2. 2. Using an external reference. REF1 is used as REFIN with the external reference source being connected to this pin. This reference is internally buffered thus, the reference sees a high impedance static load. However, there will be an error added to this reference due to the offset voltage of the internal buffer amplifier, the offset having a value of ±5 mV maximum. A 10 nF capacitor is required from REF2 to ground. This method is useful when the external reference cannot drive a 10 nF load capacitor. 3. For system gain errors less than 0.02%, REF1 is grounded and the external reference is connected to REF2. REF2 is directly connected to the on-chip modulator. With this arrangement, a capacitor of value 10 nF is required between REF2 and ground.
XTAL	The AD7721 operates with a 15 MHz crystal or with a 15 MHz external clock which is connected to the XTAL pin. The modulator samples the analog input on both phases of the clock, increasing the sampling rate to 30 MHz.
$\overline{DRDY}$	Logic Output. In parallel mode, a falling edge indicates a new output word is available for transmission. $\overline{DRDY}$ will return high upon completion of a read operation. If a read operation does not occur between output updates, $\overline{DRDY}$ will become active for two clock cycles before the next output update. In serial mode, $\overline{DRDY}$ goes high for one SCLK cycle to indicate that data is available.
$\overline{CS}$	Chip Select. When the ADC is operated in parallel mode, this input selects the device. Note that serial mode operation is attained by tying $\overline{CS}$ along with $\overline{RD}$ and $\overline{WR}$ to DGND.
$\overline{RD}$	Read. This digital input is used in conjunction with $\overline{CS}$ to read data from the device when configured for parallel mode operation.
$\overline{WR}$	Write. This digital input is used in conjunction with $\overline{CS}$ to write data to the device when the part is configured for parallel mode operation.
SDATA/DB11 STBY/DB0 DVAL/$\overline{SYNC}$	The function of these pins depends on the status of $\overline{CS}$, $\overline{RD}$ and $\overline{WR}$. Driving $\overline{CS}$ low along with $\overline{RD}$ or $\overline{WR}$ reads data or writes data to the device in the parallel mode. Tying $\overline{CS}$, $\overline{RD}$ and $\overline{WR}$ low together configures the part for serial mode operation. NOTE: All three pins must be low for a minimum of two clock cycles of the internal clock (15 MHz) before the part is configured for serial mode operation.

MODE	SDATA/DB11	$\overline{RFS}$/DB10	SCLK/DB9	DB8	CLKOUT/DB7	SINGIP/DB6	$\overline{SYNC}$/DB5
Parallel	DB11	DB10	DB9	DB8	DB7	DB6	DB5
Serial	SDATA	RFS	SCLK		CLKOUT	SINGIP	$\overline{SYNC}$

MODE	DB4	DB3	$\overline{UNI}$/DB2	CAL/DB1	STBY/DB0	DVAL/$\overline{SYNC}$
Parallel	DB4	DB3	DB2	DB1	DB0	DVAL/$\overline{SYNC}$
Serial			$\overline{UNI}$	CAL	STBY	DVAL

SERIAL MODE ONLY

For serial mode operation, $\overline{CS}$, $\overline{WR}$ and $\overline{RD}$ must be tied to DGND.

SDATA/DB11	Serial Data Output. Output serial data becomes active after $\overline{RFS}$ goes low. Sixteen bits of data are clocked out starting with the MSB. Serial data is clocked out on the rising edge of SCLK and is valid on the subsequent falling edge of SCLK.
$\overline{RFS}$/DB10	Receive Frame Synchronization. Active low logic input. This is a logic input with $\overline{RFS}$ provided externally as a strobe or framing pulse to access serial data from the output register. Alternatively, $\overline{RFS}$ may be provided by connecting this input to $\overline{DRDY}$ which is active high in the serial mode. When $\overline{RFS}$ is high, SDATA is high impedance.
SCLK/DB9	Serial Clock. Logic Input. This input serial clock can be a continuous clock or, alternatively, it can be a non-continuous clock with the information being read from the AD7721 in smaller batches of data.
CLKOUT/DB7	Serial Clock. Logic Output. The internal digital clock is provided as an output on this pin. This buffered signal can alternatively be used as the clock input to SCLK in the serial mode.
SINGIP/DB6	Single-Ended Analog Input, Digital Input. The AD7721 can accept a single-ended analog input. A logic high on the logic input SINGIP causes the pin VIN2 to be connected to the reference internally, enabling the AD7721 to accept a single-ended analog input. When SINGIP is at a logic low, the AD7721 operates with a differential input.
$\overline{SYNC}$/DB5	Synchronization Input. The internal digital filter is reset on the rising edge of a $\overline{SYNC}$ pulse. The filter reset operation requires 2048 clock cycles, throughout which $\overline{DRDY}$ remains low. Should a $\overline{SYNC}$ be requested while the part is in calibration mode, the $\overline{SYNC}$ will be acted upon immediately and the calibration will be abandoned.
$\overline{UNI}$/DB2	Analog Input Range Select, Digital Input. The analog input range can be ±1.25 V or 0 V to 2.5 V. The $\overline{UNI}$ pin is used to select the input range required. A logic high on this pin selects the ±1.25 V range while a logic low selects the 0 V to 2.5 V analog input range.
CAL/DB1	Calibration Mode Pin. When this pin is pulsed high, the part is placed in its calibration mode and both the gain and offset are calibrated. At the end of calibration, new offset and gain calibration coefficients are loaded to the calibration registers.
STBY/DB0	Standby Mode Input. Logic input used to put the device into the power save (standby) mode. The STBY pin is low for normal operation and high for standby operation. When the part is placed in the standby mode, the values in the offset and gain registers are unaffected.
DVAL/$\overline{SYNC}$	Data Valid Digital Output. An excessive overload on the modulator inputs can cause the modulator to go unstable. Once this condition is detected by internal circuits, the modulator is reset into a stable state and DVAL goes low for 2048 clock cycles. This period allows sufficient time for the modulator and digital filter to settle. An overload on the input pins can also cause clipping in the digital filter. This will cause DVAL to remain low. As well as the AD7721 indicating an overload by taking DVAL low, the AD7721 also highlights an overload by loading the output register. A positive overload causes the output register to be reset to 111 . . . 11 (unipolar input) or 011 . . . 11 (bipolar input). A negative overload causes the output register to be set to 000 . . .00 (unipolar input) or 100 . . .00 (bipolar input). When DVAL goes low, data can still be read from the interface and $\overline{DRDY}$ will continue to indicate that there is data to be read.

PARALLEL MODE ONLY

DVAL/$\overline{SYNC}$	Data Valid Digital Output/Synchronization Input depending on the status of bit DB3 in the control register. When the AD7721 is powered up, bit DB3 will be set to "0," causing this pin to be programmed as DVAL. The pin can be placed in $\overline{SYNC}$ mode by writing a "1" to bit DB3 in the control register. When changing the function of this pin from $\overline{SYNC}$ mode to DVAL mode, a logic high must be applied to the pin. DVAL: An overload in the modulator is highlighted as in the serial mode. $\overline{SYNC}$: Operates as in the serial mode except $\overline{DRDY}$ remains high while the digital filter is being reset.
SDATA/DB11–STBY/DB0	Data Outputs DB11 to DB0, DB11 being the Most Significant Bit (MSB).

SERIAL INTERFACE

The AD7721's serial communications port provides a flexible arrangement to allow easy interfacing to industry-standard microprocessors, microcontrollers and digital signal processors. The AD7721 can be operated in External-Clocking mode. This External-Clocking mode is designed for direct interface to systems that provide a serial clock output which is synchronized to the serial data output including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors. This external clock can have a frequency up to 20 MHz. Alternatively, the SCLK input can be provided by the master clock by connecting CLKOUT to SCLK. The $\overline{RFS}$ signal can also be provided by the AD7721 by connecting $\overline{RFS}$ to $\overline{DRDY}$.

Figure 2 shows the timing diagram for reading from the AD7721. $\overline{DRDY}$ goes high to indicate the presence of a new word in the output register. $\overline{DRDY}$ remains high for one internal clock (15 MHz) cycle. $\overline{RFS}$ is taken low to access data from the AD7721. The serial clock input does not have to be continuous. The serial data can be accessed in a number of bytes. However, $\overline{RFS}$ must remain low for the duration of the data transfer operation. Although the AD7721 has a 12-bit digital output in the parallel mode, sixteen bits of data are available for transmission in the serial mode, starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. $\overline{DRDY}$ rises for one internal clock cycle when a new word is available in the output register. Any earlier result still in the output register is lost at this time.

PARALLEL INTERFACE

Read Operation

The device defaults to parallel mode if $\overline{CS}$, $\overline{RD}$ and $\overline{WR}$ are not tied to DGND together. Figure 3 shows a timing diagram for reading from the AD7721 in the parallel mode. When conversion is complete, $\overline{DRDY}$ goes low to indicate that new data is available in the AD7721's output register. When the data has been read from the register using the $\overline{CS}$ and $\overline{RD}$ inputs, the $\overline{DRDY}$ pin returns high. This $\overline{DRDY}$ pin can be used to drive an edge-triggered interrupt of a microprocessor. $\overline{CS}$ and $\overline{RD}$ going low accesses the 12-bit conversion result.

Write Operation

The write operation is used for self-calibration, selecting unipolar or bipolar analog input ranges, placing the part in power down mode (standby) or programming the function of pin DVAL/$\overline{SYNC}$. When the AD7721 is placed in the write mode, data bits DB0 to DB3 and DB6 function as control bits, DB0 becoming the Standby mode bit, DB1 becoming the Calibration mode bit, DB2 being used to select the analog input range and, DB3 being used to select the function of pin DVAL/$\overline{SYNC}$. Writing a logic "1" to DB2 selects bipolar operation while a logic low selects unipolar operation. For a single-ended input in bipolar mode, DB6 (SINGIP) is taken to a logic high. When SINGIP is at a logic low, VIN2 must be provided externally. The part powers up in unipolar mode. Calibration is performed by writing a logic "1" to DB1 while the part is put into the standby mode by inputting a logic high to DB0. Writing a "1" to bit DB3 places pin DVAL/$\overline{SYNC}$ in $\overline{SYNC}$ mode while

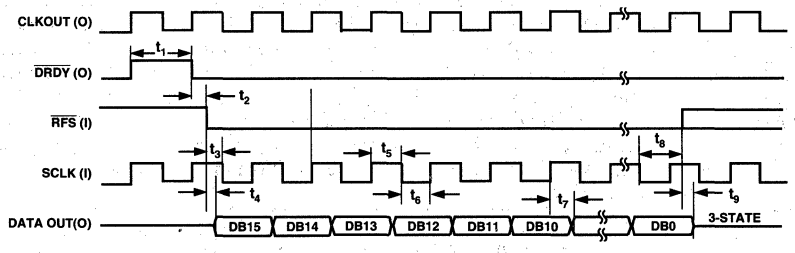

Figure 2. Serial Mode Output Register Read

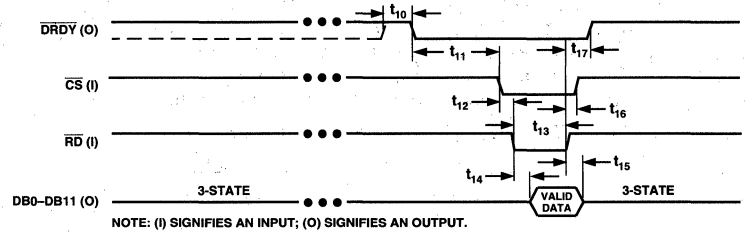

Figure 3. Parallel Mode Output Register Read

writing a "0" places the pin in DVAL mode. $\overline{CS}$ and $\overline{WR}$ going low places this information in the control register. Figure 4 shows a timing diagram for the write operation. Bits DB4 to DB5 and bits DB7 to DB15 are used to test the AD7721 in parallel mode. Thus, for normal operation, a logic "0" is inputted to these bits.

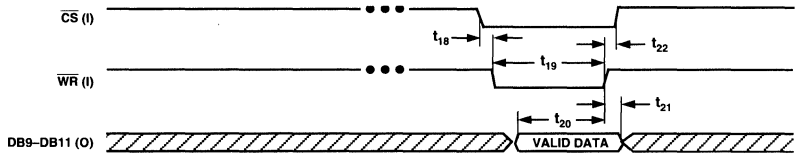

Figure 4. Write Timing Diagram

READ	DB11	DB10	DB9	DB8	DB7	DB6	DB5	DB4
WRITE	0	0	0	0	0	SINGIP	0	0

READ	DB3	DB2	DB1	DB0

Figure 5. Control Register

ANALOG INPUT

In the bipolar mode configuration, the analog input range is ±1.25 V. The designed code transitions occur midway between successive integer LSB values. The output code is 2s complement binary with 1 LSB = 0.61 mV in parallel mode and 38 µV in serial mode. The ideal input/output transfer function is illustrated in Figure 6.

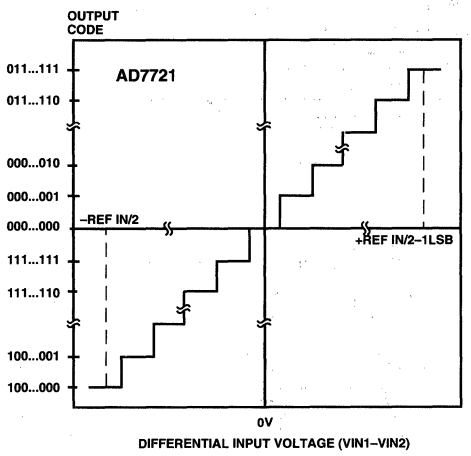

Figure 6. Bipolar Mode Transfer Function

In the unipolar mode, the analog input range is 0 V to 2.5 V. Again, the designed code transitions occur midway between successive integer LSB values. The output code is straight binary with 1 LSB = 0.61 mV in parallel mode and 38 µV in serial mode. The ideal input/output transfer function is shown in Figure 7.

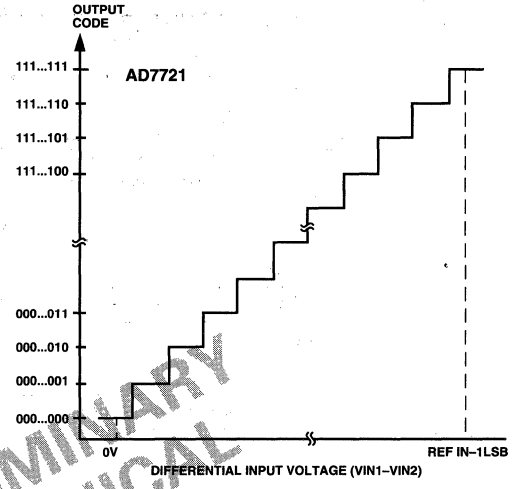

Figure 7. Unipolar Mode Transfer Function

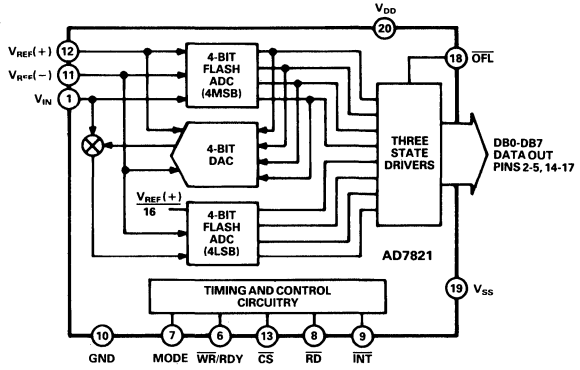
LC²MOS High Speed, µP-Compatible 8-Bit ADC with Track/Hold Function

AD7821

FEATURES

- **Fast Conversion Time: 660 ns max**
- **100 kHz Track-and-Hold Function**
- **1 MHz Sample Rate**
- **Unipolar and Bipolar Input Ranges**
- **Ratiometric Reference Inputs**
- **No External Clock**
- **Extended Temperature Range Operation**
- **Skinny 20-Pin DIPs, SOIC and 20-Terminal Surface Mount Packages**

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7821 is a high-speed, 8-bit, sampling, analog-to-digital converter that offers improved performance over the popular AD7820. It offers a conversion time of 660 ns (vs. 1.36 µs for the AD7820) and 100 kHz signal bandwidth (vs. 6.4 kHz). The sampling instant is better defined and occurs on the falling edge of $\overline{WR}$ or $\overline{RD}$. The provision of a V_{SS} pin (Pin 19) allows the part to operate from ±5 V supplies and to digitize bipolar input signals. Alternatively, for unipolar inputs, the V_{SS} pin can be grounded and the AD7821 will operate from a single +5 V supply, like the AD7820.

The AD7821 has a built-in track-and-hold function capable of digitizing full-scale signals up to 100 kHz max. It also uses a half-flash conversion technique that eliminates the need to generate a CLK signal for the ADC.

The AD7821 is designed with standard microprocessor control signals ($\overline{CS}$, $\overline{RD}$, $\overline{WR}$, RDY, $\overline{INT}$) and latched, three-state data outputs capable of interfacing to high-speed data buses. An overflow output ($\overline{OFL}$) is also provided for cascading devices to achieve higher resolution.

The AD7821 is fabricated in Linear-Compatible CMOS (LC²MOS), an advanced, mixed technology process combining precision bipolar circuits with low-power CMOS logic. The part features a low power dissipation of 50 mW.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time
   The half-flash conversion technique, coupled with fabrication on Analog Devices' LC²MOS process, enables a very fast conversion time. The conversion time for the WR-RD mode is 660 ns, with 700 ns for the RD mode.
2. Built-In Track-and-Hold
   This allows input signals with slew rates up to 1.6 V/µs to be converted to 8-bits without an external track-and-hold. This corresponds to a 5 V peak-to-peak, 100 kHz sine-wave signal.
3. Total Unadjusted Error
   The AD7821 features an excellent total unadjusted error figure of less than ±1 LSB over the full operating temperature range.
4. Unipolar/Bipolar Input Ranges
   The AD7821 is specified for single supply (+5 V) operation with a unipolar full-scale range of 0 to +5 V, and for dual supply (±5 V) operation with a bipolar input range of ±2.5 V. Typical performance characteristics are given for other input ranges.
5. Dynamic Specifications for DSP Users
   In addition to the traditional ADC specifications, the AD7821 is specified for ac parameters, including signal-to-noise ratio, distortion and slew rate.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7821—SPECIFICATIONS

V_{DD} = +5 V ± 5%, GND = 0 V. Unipolar Input Range: V_{SS} = GND, $V_{REF}(+)$ = 5 V, $V_{REF}(-)$ = GND. Bipolar Input Range: V_{SS} = −5 V ± 5%, $V_{REF}(+)$ = 2.5 V, $V_{REF}(-)$ = −2.5 V. These test conditions apply unless otherwise stated. All specifications T_{min} to T_{max} unless otherwise stated. Specifications apply for RD Mode (Pin 7 = 0 V).

t_{ID}[3]					Data Access Time after $\overline{INT}$ (Stand-Alone Operation)
	30	35	40	ns max	C_L = 20 pF
	45	60	70	ns max	C_L = 100 pF

NOTES
[1]Sample tested at +25°C to ensure compliance. All input control signals are specified with tr = tf = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.
[2]C_L = 50 pF.
[3]Measured with load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[4]Defined as the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

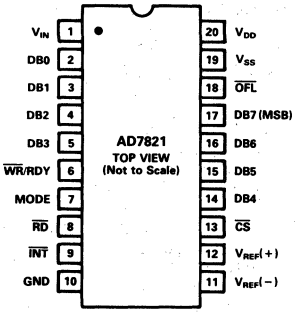
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

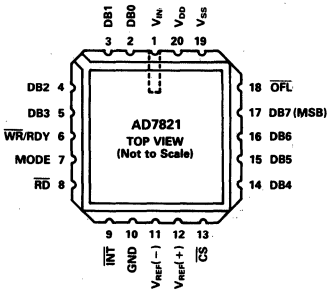
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN CONFIGURATIONS

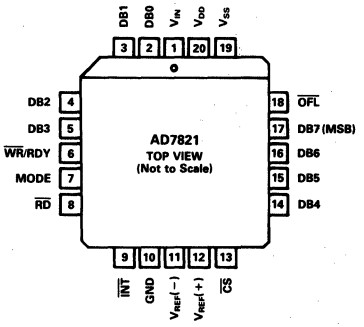
DIP AND SOIC



LCCC



PLCC



PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	V_{IN}	Analog Input: Range $V_{REF}(-) \le V_{IN} \le V_{REF}(+)$.
2	DB0	Three-State Data Output (LSB).
3–5	DB1–DB3	Three-State Data Outputs.
6	$\overline{WR}$/RDY	WRITE control input/READY status output. See Digital Interface section.
7	MODE	Mode Selection Input. It determines whether the device operates in the WR-RD or RD mode. This input is internally pulled low through a 50 μA current source. See Digital Interface section.
8	$\overline{RD}$	READ Input. $\overline{RD}$ must be low to access data from the part. See Digital Interface section.
9	$\overline{INT}$	INTERRUPT Output. $\overline{INT}$ going low indicates that the conversion is complete. $\overline{INT}$ returns high on the rising edge of $\overline{CS}$ or $\overline{RD}$. See Digital Interface section.
10	GND	Ground.
11	$V_{REF}(-)$	Lower limit of reference span. Range: $V_{SS} \le V_{REF}(-) < V_{REF}(+)$.
12	$V_{REF}(+)$	Upper limit of reference span. Range: $V_{REF}(-) < V_{REF}(+) \le V_{DD}$.
13	$\overline{CS}$	Chip Select Input. The device is selected when this input is low.
14–16	DB4–DB6	Three-State Data Outputs.
17	DB7	Three-State Data Output (MSB).
18	$\overline{OFL}$	Overflow Output. If the analog input is higher than ($V_{REF}(+) - 1/2$ LSB), $\overline{OFL}$ will be low at the end of conversion. It is a non-three-state output which can be used to cascade 2 or more devices to increase resolution.
19	V_{SS}	Negative supply voltage. V_{SS} = 0 V; Unipolar Operation. V_{SS} = −5 V; Bipolar Operation.
20	V_{DD}	Positive supply voltage, +5 V.

3 V to 5 V Single Supply, 200 kSPS, Single/Multichannel 12-Bit Sampling ADCs

AD7853/AD7858

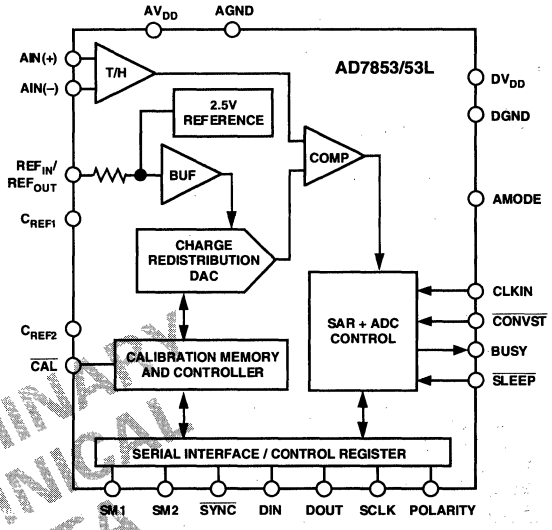
FEATURES

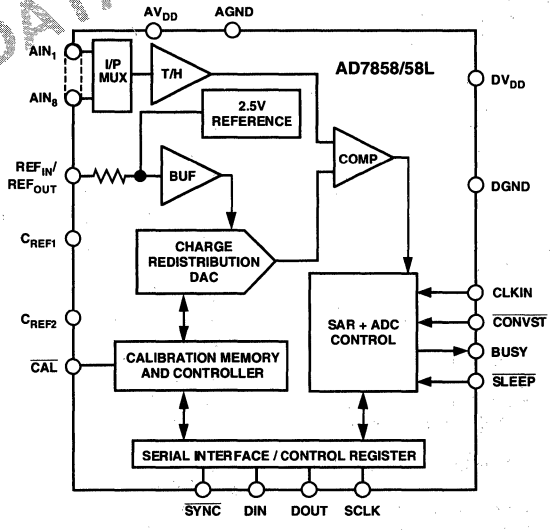
Battery-Compatible Supply Voltage: Guaranteed Specs for V_{DD} of 3 V to 5.5 V
AD7853/AD7858: 200 kSPS, AD7853L/AD7858L: 100 kSPS
Pseudo-Differential Input with Two Input Ranges (AD7853)
8 Single Ended or 4 Pseudo-Differential Inputs (AD7858)
Self and System Calibration
Read/Write Capability of Calibration Data
Low Power
AD7853/AD7858: 15 mW (V_{DD} = 3 V)
AD7853L/AD7858L: 5.5 mW (V_{DD} = 3 V)
Power-Down Mode: 25 μW Power Consumption
Flexible Serial Interface
Three-Wire SPI Compatible
Two-Wire 8051 Compatible
24-Pin DIP, SOIC and SSOP Packages

APPLICATIONS

Battery-Powered Systems (Portable PCs, Personal Digital Assistants (PDAs))
Pen Computers
Instrumentation and Control Systems
High Speed Modems

FUNCTIONAL BLOCK DIAGRAMS





GENERAL DESCRIPTION

The AD7853/AD7858 are high speed, low power, 12-bit ADCs that operate from a single 3 V or 5 V power supply, the AD7853 being the single channel version and the AD7858 the multichannel version. The ADCs contain self-calibration and system calibration options to ensure accurate operation over time and temperature.

The AD7853/AD7858 is capable of 200 kHz throughput rate. The input track-and-hold acquires a signal in 500 ns and features a pseudo-differential sampling scheme. The AD7853 has the added advantage of two input voltage ranges (0 V to V_{REF} and $-V_{REF}/2$ to $+V_{REF}/2$). Input signal range is to the supply and the part is capable of converting full power signals to 100 kHz.

CMOS construction ensures low power dissipation (18 mW typ) with power-down mode (25 μW typ). The part is available in 24-pin, 0.3 inch-wide DIP, 24-lead SOIC and 24-lead SSOP packages.

PRODUCT HIGHLIGHTS

1. Operation with either 3 V or 5 V power supplies.
2. Operates with reference voltages from 1.2 V to the supply.
3. Unipolar analog input range from 0 V to V_{SUPPLY}.
4. Self and System calibration including power-down mode.
5. Versatile serial I/O port.
6. Single channel (AD7853) or 8 channel (AD7858).

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

[4]Specifications written within parentheses ( ) refer to the AD7853L/AD7858L.

[5]Full-scale error match is the worst case of the positive full-scale error match or the negative full-scale error match.

[6]Sample tested @ +25°C to ensure compliance.

Specifications subject to change without notice.

TIMING SPECIFICATIONS[1, 2] (V_{DD} = +3.0 V to +5.5 V; f_{CLKIN} = 4 MHz; T_A = T_{MIN} to T_{MAX}, unless otherwise noted)

Parameter	Limit at T_{MIN}, T_{MAX} (A, B, S Versions)	Units	Description
f_{CLKIN}	500	kHz min	Master Clock Frequency
	4	MHz max	(2 MHz for the AD7853L/AD7858L)
f_{SCLK}	$f_{CLK\ IN}$	MHz max	Serial Clock Input Frequency
t_1	100[3]	ns min	$\overline{CONVST}$ Pulse Width
t_2	50	ns max	$\overline{CONVST}$ to BUSY Propagation Delay
$t_{CONVERT}$	4.5 (18 × t_{CLKIN})	μs max	Conversion Time
t_3	60 (60/0.4 × t_{SCLK})	ns min (min/max)	$\overline{SYNC}$ to SCLK falling Edge Setup Time (Continuous SCLK input).
t_{3A}	60	ns min	$\overline{SYNC}$ to SCLK falling Edge Setup Time (AD7853 only).
t_4	60[4]	ns max	Delay from $\overline{SYNC}$ until DOUT 3-state disabled.
t_{4A}	70[4]	ns max	Delay from $\overline{SYNC}$ until DIN 3-state disabled.
t_5	60[4]	ns max	Data Access time after falling edge of SCLK.
t_6	40	ns min	Data Setup Time Prior to rising edge of SCLK.
t_7	0	ns min	Data Valid to SCLK Hold Time.
t_8	0.4 × t_{SCLK}[5]	ns min	SCLK High Pulse Width
t_9	0.4 × t_{SCLK}[5]	ns min	SCLK Low Pulse Width
t_{10}	30 (30/0.4 × t_{SCLK})	ns min (min/max)	SCLK Rising Edge to $\overline{SYNC}$ Hold Time (Continuous SCLK).
t_{10A}	30	ns min	SCLK Rising Edge to $\overline{SYNC}$ Hold Time (AD7853 only).
t_{11}	60[4]	ns max	Delay from $\overline{SYNC}$ until DOUT 3-state enabled.
t_{11A}	70[4]	ns max	Delay from $\overline{SYNC}$ until DIN 3-state enabled.
t_{12}	80[4]	ns max	Delay from SCLK to DIN being configured as output.
t_{13}	60[4]	ns max	Delay from SCLK to DIN being configured as input.
t_{14}	100	ns max	$\overline{CAL}$ Rising Edge to BUSY delay.
t_{15}	50	ns max	$\overline{CONVST}$ to BUSY delay in calibration sequence.
t_{CAL}	N_2 × t_{CLKIN}		Full self calibration time, N_2 an integer.
t_{CAL1}	N_3 × t_{CLKIN}		Internal DAC plus system full-scale calibration time, N_3 an integer.
t_{CAL2}	N_4 × t_{CLKIN}		System offset calibration time, N_4 an integer.

NOTES

[1]Sample tested at +25°C to ensure compliance. The timing figures here are for the AD7853/AD7858 only and not for the AD7853L/AD7858L, so the timing figures for the AD7853L/AD7858L will reflect that the AD7853L/AD7858L operates at half the speed of the AD7853, and an example of this is given with the max master clock frequency of 2.5 MHz for the AD7853L/AD7858L. All input signals are specified with tr = tf = 5 ns (10% to 90% of V_{DD}) and timed from a voltage level of 1.6 V.

[2]See Table I and Figures 2, 4, 5, 6, 8 where all the timing diagrams are for ADC output data as distinct from calibration or control register data in which case there would not be the 4 leading zeros with the output data. Instead there would be 4 data bits DB15–DB12 in their place.

[3]The $\overline{CONVST}$ pulse width will depend on the way the part is being operated. For operation where the BUSY is not connected to the $\overline{SLEEP}$ pin then the $\overline{CONVST}$ pulse width is 100 ns min as stated above. If BUSY is connected to the $\overline{SLEEP}$ pin so that the part goes into sleep mode after conversion the conversion time will be different and will also be dependent on the PMGT bit in the control register.

[4]t_4 is measured with the load circuit of Figure 1 and defined as the time required for the output to cross 0.8 V or 2.4 V.

[5]SCLK mark/space ratio (measured from a voltage level of 1.6 V) is 40/60 to 60/40.

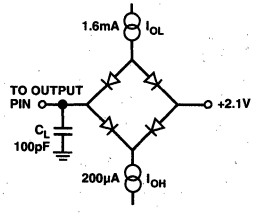

Figure 1. Load Circuit for Digital Output Timing Specifications

TYPICAL TIMING DIAGRAM

All the timing diagrams (Figures 2–9) are for ADC output data from the part, and this is why there are 4 leading zeros before the 12 bits of data. However for a control register or calibration register read, there will not be 4 leading zeros on the output data. These 4 leading zeros will be replaced by data bits DB15–DB12 for this read operations.

In Figure 2 below we have a typical read and write timing diagram with the $\overline{\text{CONVST}}$ and BUSY. The essence of this is to show exactly what most of the timing numbers relate to. Here the reading from and writing to the part is shown after the conversion so in this case the maximum conversion rate cannot be achieved. To achieve the maximum throughput rate of 100 kHz (AD7853L) or 200 kHz (AD7853) the user must read from and write to the part during conversion.

There is a very useful mode of operation for reducing power consumption. In this power save mode of operation the BUSY can be connected to the $\overline{\text{SLEEP}}$ pin so that at the end of conversion the part automatically goes into sleep mode. However on the next $\overline{\text{CONVST}}$ pulse, the part then must be allowed a reasonable time to "wake up" before converting the signal on the AIN pin. Thus the $\overline{\text{CONVST}}$ pulse width must be made longer and will extend well beyond the rising edge of the BUSY (see specification for $\overline{\text{CONVST}}$ pulse width) so that it caters for what is called "wake-up" time.

NOTE: $t_{CONVERT}$ = 4.5 µs MAX, t_1 = 100 ns MIN, t_5 = 60 ns MAX, t_6 = 40 ns MIN, t_7 = 0 ns MIN.

Figure 2. AD7853 Timing Diagram (Typical Read or Write Operation)

ABSOLUTE MAXIMUM RATINGS[1]

(T_A = +25°C unless otherwise noted)

AV_{DD} to AGND ..... –0.3 V to +7 V
DV_{DD} to DGND ..... –0.3 V to +7 V
Analog Input Voltage to AGND ..... –0.3 V to AV_{DD} + 0.3 V
Digital Input Voltage to DGND .... –0.3 V to DV_{DD} + 0.3 V
Digital Output Voltage to DGND ... –0.3 V to DV_{DD} + 0.3 V
REF_{IN}/REF_{OUT} to AGND ..... –0.3 V to AV_{DD} + 0.3 V
Input Current to any Pin except Supplies[2] ..... ±10 mA
Operating Temperature Range
  Commercial (A, B Versions) ..... –40°C to +85°C
  Storage Temperature Range ..... –65°C to +150°C
Junction Temperature ..... +150°C
Plastic DIP Package Power, Power Dissipation ..... 450 mW
  θ_{JA} Thermal Impedance ..... 105°C/W
  θ_{JC} Thermal Impedance ..... 35°C/W
  Lead Temperature (Soldering, 10 sec) ..... +260°C
SOIC, SSOP Package, Power Dissipation ..... 450 mW
  θ_{JA} Thermal Impedance . 75°C/W (SOIC) 115°C/W (SSOP)
  θ_{JC} Thermal Impedance .. 25°C/W (SOIC) 35°C/W (SSOP)
  Lead Temperature, Soldering
    Vapor Phase (60 sec) ..... +215°C
    Infrared (15 sec) ..... +220°C

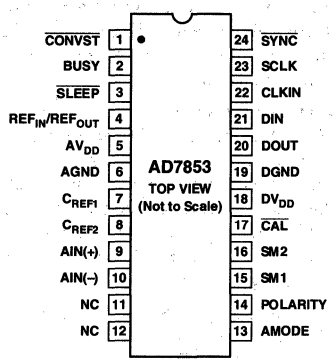
NOTES

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

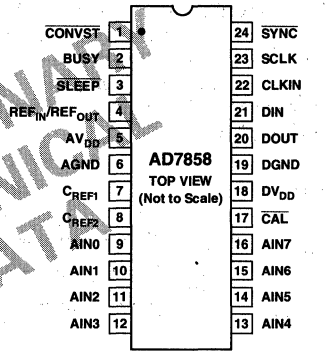
[2]Transient currents of up to 100 mA will not cause SCR latch up.

PIN CONFIGURATIONS

DIP, SOIC and SSOP



NC = NO CONNECT



CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7853/AD7858 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

AD7853 PIN DESCRIPTIONS

Pin	Mnemonic	Description
1	$\overline{\text{CONVST}}$	Convert start. Logic input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion.
2	BUSY	Busy output. The busy output goes high when conversion begins (note that BUSY goes high before $\overline{\text{CONVST}}$ goes high) and stays high until conversion is completed, at which time it goes low. BUSY is also used to indicate when the AD7853 has completed its on-chip calibration sequence.
3	$\overline{\text{SLEEP}}$	Sleep input/Low power mode. With this pin logic low all circuitry is powered down including the internal voltage reference. Calibration data is retained. With the pin logic high normal operation results.
4	REF_{IN}/REF_{OUT}	Reference input/output. This pin is connected to the internal reference via a resistor so that the reference voltage appears at this pin from the internal reference. An external reference can be applied to overdrive this pin. This pin is the reference source for the analog-to-digital converter, and the nominal reference voltage is 2.5 V but can be as high as AV_{DD} to give a larger reference for the analog-to-digital converter.
5	AV_{DD}	Analog positive supply voltage, +3.0 V to +5.5 V.
6	AGND	Analog ground. Ground reference for track/hold, reference and DAC.
7	C_{REF1}	Reference capacitor (0.1 μF multilayer ceramic). This external capacitor is used as a charge source for the internal DAC.
8	C_{REF2}	Reference capacitor (0.01 μF ceramic disc). This external capacitor is used in conjunction with the on-chip reference.
9	AIN(+)	Analog input. Positive input of the differential analog input.
10	AIN(–)	Analog input. Negative input of the differential analog input.
11, 12	NC	No Connect pins.
13	AMODE	Analog mode pin. This pin allows two different analog input ranges to be selected: A logic 0 selects range 0 to V_{REFIN} (i.e., AIN(+) – AIN(–) = 0 to V_{REFIN}). A logic 1 selects range $-V_{REFIN}/2$ to $+V_{REFIN}/2$ (i.e., AIN(+) – AIN(–) = $-V_{REFIN}/2$ to $+V_{REFIN}/2$).
14	POLARITY	This pin determines the edge of the serial clock (SCLK) on which the data is latched and transferred to the DOUT pin or latched from the DIN pin. Depending on the mode of operation then the output data can be clocked out on the rising or falling edge of the serial clock (SCLK). The data input is always latched on the rising edge of the serial clock (SCLK) regardless of the state of the POLARITY pin. It is best to see the timing diagrams for each of the operating modes to see which edges of the SCLK are critical for the output data and for the input data. All the timing diagrams are with the POLARITY pin high, so bringing the POLARITY pin low will reverse the edge of the SCLK that the data input is latched in on and will also reverse the edge of the SCLK that the output data is clocked out on.
15	SM1	Serial mode select pin. When this pin is high, the device is in its self-clocking mode; when it is low, the device is in its external clocking mode. This pin is used in conjunction with SM2 to give different modes of operation as shown in Table III.
16	SM2	Serial mode select pin. This pin is used in conjunction with the SM1 pin in order to give the different modes of operation as shown in Table III.
17	$\overline{\text{CAL}}$	Calibration input. A logic 0 on this input resets all logic and initiates a calibration on its rising edge. This input overrides all other internal operations.
18	DV_{DD}	Digital supply voltage, +3.0 V to +5.5 V.
19	DGND	Digital ground. Ground reference point for digital circuitry.
20	DOUT	Serial data output. The data output is supplied to this pin as a 16-bit serial word.
21	DIN	Serial data input. The data to be loaded to the control register is applied to this pin in serial form (16-bit word). This pin can act as an input pin or as a I/O pin depending on the mode the part is in (see Table III).
22	CLKIN	Master clock signal for the device (4 MHz). Sets the conversion and calibration times.
23	SCLK	Serial port clock. Logic input/output. The SCLK pin is configured as an input or output, dependent on the type of serial data transmission (self-clocking or external-clocking) that has been selected by the SM1 and SM2 pins. The data is latched on the rising or falling edge of SCLK depending on the POLARITY input logic level.
24	$\overline{\text{SYNC}}$	This pin can be an input level triggered active low (similar to a chip select in one case and to a frame sync in the other case) or an output (similar to a frame sync) pin depending on SM1 and SM2 (see Table III).

AD7858 PIN DESCRIPTIONS

Pin	Mnemonic	Description
1	$\overline{\text{CONVST}}$	Convert start. Logic input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion. If the $\overline{\text{CONVST}}$ is tied to the BUSY pin, then the part will go into sleep mode once conversion is complete and on the next conversion cycle the part needs to "wake-up" before a conversion can take place.
2	BUSY	Busy output. The busy output goes high when conversion begins (note that BUSY goes high before $\overline{\text{CONVST}}$ goes high) and stays high until conversion is completed, at which time it goes low. BUSY is also used to indicate when the AD7858 has completed its on-chip calibration sequence.
3	$\overline{\text{SLEEP}}$	Sleep input/low power mode. With this pin logic low all circuitry is powered down including the internal voltage reference. Calibration data is retained. With the pin logic high normal operation results.
4	REF_{IN}/REF_{OUT}	Reference input/output. This pin is connected to the internal reference via a resistor so that the reference voltage appears at this pin from the internal reference. An external reference can be applied to overdrive this pin. This pin is the reference source for the analog-to-digital converter and the nominal reference voltage is 2.5 V. However this pin can be taken as high as AV_{DD} to give a larger reference for the analog-to-digital converter.
5	AV_{DD}	Analog positive supply voltage, +3.0 V to +5.5 V.
6	AGND	Analog ground. Ground reference for track/hold, reference and DAC.
7	C_{REF1}	Reference capacitor (0.1 μF multilayer ceramic). This external capacitor is used as a charge source for the internal DAC.
8	C_{REF2}	Reference capacitor (0.01 μF ceramic disc). This external capacitor is used in conjunction with the on-chip reference.
9–16	AIN_1–AIN_8	Analog inputs. Eight analog inputs which can be used as eight single ended inputs (referenced to AGND) or four pseudo differential inputs where AIN_1 would be the positive input and AIN_2 would be the negative input and similarly for pairs AIN_3 AIN_4, AIN_5 AIN_6, and AIN_7 AIN_8. Pseudo differential means that the negative input cannot be taken below AGND. The selection of single ended or pseudo differential channels can be programmed via the SGL/$\overline{\text{DIFF}}$ bit in the control register, and also the channel to be selected for conversion can be programmed by the bits CHSLT0, CHSLT1, CHSLT2 in the control register.
17	$\overline{\text{CAL}}$	Calibration input. A logic 0 on this input resets all logic and initiates a calibration on its rising edge. This input overrides all other internal operations (see Figure 5).
18	DV_{DD}	Digital supply voltage, +3.0 V to +5.5 V.
19	DGND	Digital ground. Ground reference point for digital circuitry.
20	DOUT	Serial data output. The data output is supplied to this pin as a 16-bit serial word.
21	DIN	Serial data input. The data to be loaded to the control register is applied to this pin in serial form (16-bit word). This pin can act as an input pin or as a I/O pin depending on the mode the part is in (see Operating Modes).
22	CLKIN	Master clock signal for the device (4 MHz). Sets the conversion and calibration times.
23	SCLK	Serial port clock. The SCLK pin is configured as an input pin, and the user must provide 16 clock pulses at this pin for correct operation. The input data is latched on the rising edge of SCLK, and the output data is clocked out on the falling edge of SCLK (see timing diagrams).
24	$\overline{\text{SYNC}}$	The user must provide a frame sync signal at this pin and this signal is level triggered active low. This pin can be tied permanently low. When this input is high then the part will not read in the input data and output data will also be disabled.

CONTROL/STATUS REGISTER

The power-up/default state of all bits in the control/status register is 0.

When writing to the control register, the first two bits are used in determining whether it is the control/status register or the calibration register that is being written to. A 11 in the first two bits ensures that it is the control/status register that you are writing to, and a 10 tells the part that it is the calibration register that is being written to. Also a 00 in the first two bits does not have any effect and a 01 is not allowed.

Bit	Mnemonic	Comment
0	STCAL	Start calibration bit. The type of calibration is determined by the setting of CALSLT1 and CALSLT2 and also whether it is a system or device calibration is set by the calibration mode (CALMD) bit. The default/Power up setting is for full device calibration (*i.e., calibration of DAC, Offset, and Gain*).
1 2	CALSLT1 CALSLT2	These two bits are for calibration control so that one can select the type of calibration that is to be performed depending on the value of the bits. A 00 will give a full DAC + Offset + Gain calibration, a 01 will give an Offset + Gain calibration, a 10 combination will give just an Offset calibration, and a 11 will give a Gain calibration. The calibration can be a system or device calibration depending on the setting of the calibration mode bit (see Table I).
3	CALMD	This is the calibration mode bit. A 0 here selects the device itself for calibration and a 1 selects a system calibration. The default/power-up state is a 0 so that it is a device calibration is selected unless this bit is changed (see Table I).
4	$\overline{\text{CONVST}}$	This is the conversion start bit. This is used for initiating a conversion start and it is also used in conjunction with system calibration as shown in the calibration timing diagram of Figure 6.
5	2/$\overline{3}$ MODE	The interface mode select bit. With this bit set to 1 the two-wire interface mode is enabled where DIN is used as an output as well as an input.
6 7	RDSLT1 RDSLT2	Theses two bits determine what data is going to be read from the part. ADC data will be read when the bits are set to 00, a 01 combination is used for test purposes and contains no useful user information, a 10 combination allows reading of the calibration register data, and a 11 ensures reading of control register data.
8	$\overline{\text{SLEEP}}$	This is the sleep bit which puts the device into sleep mode when 1 and the extent of the power down is determined by the power management bit.
9	PMGT	Power management bit. With this set to 0 then when put into sleep mode there will be a full power down whereas if set to 1 there will only be a selective power down.
10 11 12	*CHSLT0 *CHSLT1 *CHSLT2	(AD7858 only, should be 0 for AD7853.) These three bits are used to select the channel to be converted. With three bits then we can address all the eight channels. One should refer to Table II for the combinations of these three bits for different channel selections. The default selection is the pseudo differential mode with positive channel AIN_1 and negative channel AIN_2.
13	*SGL/$\overline{\text{DIFF}}$	(AD7858 only, should be 0 for AD7853) This is the bit which determines whether the input channels are in the single ended mode or in the pseudo differential mode. With this bit set to 1 then the singled ended mode is enabled. The default setting of this bit is 0 so that the input channels are in the pseudo differential mode. This bit is used in conjunction with the three channel selection bits CHSLT0, CHSLT1, CHSLT2 and one should refer to Table II for the bit combinations for different selections.
14	BUSY	This is the conversion/calibration busy bit which is read only and tells you when the part is finished conversion or calibration.

It is important to note that in writing to the control register it is Bit 15 (the MSB) that is the first bit in the data stream and not Bit 0, so that the first bit to be written to the control register will be Bit 15 then Bit 14, Bit 13 and so on down to Bit 0.

*These bits for the channel selection and the channel configuration are only valid for the AD7858 and for the AD7853 these bits must all be made 0 when writing to the control register.

Shown below are the tables for the different types of calibration and the different types of configurations for the analog inputs (AD7858 only) that can be selected in the control register.

Table I. Calibration Selection in the Control Register (AD7853/AD7858)

CALSLT2	CALSLT1	CALMD	Calibration Type
0	0	0	A full internal calibration is initiated where the internal DAC is calibrated then the Internal Offset Error is calibrated out and finally the Internal Gain Error is calibrated out.
0	0	1	A full system calibration is initiated here where firstly the Internal DAC is calibrated and then the System Offset Error is calibrated out and finally the System Gain Error is calibrated out.
0	1	0	Here the Internal Offset Error is calibrated out and then the Internal Gain Error is calibrated out.
0	1	1	Here the System Offset Error is calibrated out and then the System Gain Error is calibrated out.
1	0	0	This calibrates out the Internal Offset Error only.
1	0	1	This calibrates out the System Offset Error only.
1	1	0	This calibrates out the Internal Gain Error only.
1	1	1	This calibrates out the System Gain Error only.

NOTE
There is more information on the calibration features of the part under the Calibration section of this data sheet.

Table II. Multichannel Selection in the Control Register for the AD7858

SGL/$\overline{\text{DIFF}}$	CHSLT2	CHSLT1	CHSLT0	CH(+)	CH(–)
0	0	0	0	AIN_1	AIN_2
0	0	0	1	AIN_3	AIN_4
0	0	1	0	AIN_5	AIN_6
0	0	1	1	AIN_7	AIN_8
0	1	0	0	AIN_2	AIN_1
0	1	0	1	AIN_4	AIN_3
0	1	1	0	AIN_6	AIN_5
0	1	1	1	AIN_8	AIN_7
1	0	0	0	AIN_1	AGND
1	0	0	1	AIN_3	AGND
1	0	1	0	AIN_5	AGND
1	0	1	1	AIN_7	AGND
1	1	0	0	AIN_2	AGND
1	1	0	1	AIN_4	AGND
1	1	1	0	AIN_6	AGND
1	1	1	1	AIN_8	AGND

NOTE
The four selection bits are in the control register.

TERMINOLOGY[1]

Integral Nonlinearity
This is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints of the transfer function are zero scale (*which is AIN(+) = AIN(–) –1/2 LSB in unipolar mode (AD7853/AD7858), and AIN(+) = AIN(–) –V_{REF}/2 – 1/2 LSB in bipolar mode (AD7853 only)*), a point 1/2 LSB below the first code transition (00 . . . 000 to 00 . . . 001) and full scale (*which is AIN(+) = AIN(–) + V_{REF} + 1/2 LSB in unipolar range (AD7853/AD7858), and AIN(+) = AIN(–) +V_{REF}/2 + 1/2 LSB in bipolar mode (AD7853 only)*), a point 1/2 LSB above the last code transition (11 . . . 110 to 11 . . . 111).

Differential Nonlinearity
This is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Unipolar Offset Error
This is the deviation of the first code transition (00 . . . 000 to 00 . . . 001) from the ideal AIN(+) voltage (AIN(–) + 1/2 LSB) when operating in the unipolar mode.

Positive Full-Scale Error
This applies to the unipolar and bipolar modes and is the deviation of the last code transition (11 . . . 110 to 11 . . . 111 (*for unipolar mode (AD7853/AD7858)*) and 01 . . . 110 to 01 . . . 111 (*for bipolar mode (AD7853 only)*) from the ideal (AIN(+) = AIN(–) + Full Scale – 1.5 LSB) after the offset error (*unipolar offset error or bipolar offset error*) has been adjusted out.

Negative Full-Scale Error
This applies to the bipolar mode only and is the deviation of the first code transition (10 . . . 000 to 10 . . . 001) from the ideal (AIN(+) = AIN(–) – V_{REF}/2 + 0.5 LSB (*bipolar mode (AD7853 only)*)).

Bipolar Zero Error
This is the deviation of the midscale transition (all 0s to all 1s) from the ideal AIN(+) voltage (AIN(–) – 1/2 LSB).

Channel-to-Channel Isolation
Channel-to-channel isolation is a measure of the level of crosstalk between channels. It is measured by applying a full-scale 1 kHz signal to the other seven inputs and determining how much that signal is attenuated in the channel of interest. The figure given is the worst case for all channels.

Track/Hold Acquisition Time
Track/hold acquisition time is the time required for the output of the track/hold amplifier to reach its final value, within ±1/2 LSB, after the end of conversion (*the point at which the track/hold returns into track mode*). It also applies to a situation where a change in the selected input channel takes place (AD7858 only) or where there is a step input change on the input voltage applied to the selected V_{IN} input of the AD7853/AD7858. It means that the user must wait for the duration of the track/hold acquisition time after the end of conversion or after a channel change/step input change to V_{IN} before starting another conversion, to ensure the part operates to specification.

[1]AIN(–) refers to the negative input of the pseudo differential input pairs or to AGND for the AD7858 depending on the channel configuration, and AIN(–) refers to the negative input for the AD7853.

Signal to (Noise + Distortion) Ratio
This is the measured ratio of signal to (noise + distortion) at the output of the A/D converter. The signal is the rms amplitude of the fundamental. Noise is the sum of all nonfundamental signals up to half the sampling frequency (f_S/2), excluding dc. The ratio is dependent on the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to (noise + distortion) ratio for an ideal N-bit converter with a sine wave input is given by:

$$Signal\ to\ (Noise + Distortion) = (6.02N + 1.76)\ dB$$

Thus for a 12-bit converter, this is 74 dB.

Total Harmonic Distortion
Total harmonic distortion (THD) is the ratio of the rms sum of harmonics to the fundamental. For the AD7853, it is defined as:

$$THD\ (dB) = 20 \log \sqrt{(V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2)/V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonics.

Peak Harmonic or Spurious Noise
Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to f_S/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor, it will be a noise peak.

Intermodulation Distortion
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation distortion terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa + fb) and (fa – fb), while the third order terms include (2fa + fb), (2fa – fb), (fa + 2fb) and (fa – 2fb).

The AD7853 is tested using the CCIF standard where two input frequencies near the top end of the input bandwidth are used. In this case, the second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

Table III. Digital Interface Operating Modes

No.	SM1	SM2	$\overline{SYNC}$	DIN	DOUT	SCLK	Comment
1 (AD7853/AD7858)	0	0	I/P[1]	I/O	(O/P)[2]	I/P	**TWO-WIRE MODE (8051).** In this mode of operation the user must supply the serial clock (SCLK with a total of 16 clock cycles). This mode can only be entered by programming the interfaced mode select (2/$\overline{3}$ MODE) bit in the control register. The $\overline{SYNC}$ pin must also be provided by the user; it is level triggered and can be tied low permanently in this mode. The DIN pin is used for inputting the data (in serial form) as well as providing the output data in serial form.
2 (AD7853/AD7858)	0	0	I/P[1]	I/P	O/P	I/P	**THREE-WIRE MODE (SPI).** In this mode of operation the user must supply the frame sync signal ($\overline{SYNC}$) and serial clock (SCLK with a total of 16 clock cycles). This is the default mode. Here the DOUT pin is used for the output data and DIN pin is used for the input data only.
3 (AD7853 Only)	0	1	I/P[3]	I/P	O/P	I/P	**DSP MASTER MODE.** In this mode of operation a frame sync input is needed at the $\overline{SYNC}$ pin and a serial clock SCLK is needed with a continuous clock or 16 clock cycles from when the $\overline{SYNC}$ goes low.
4 (AD7853 Only)	1	0	O/P[3]	I/P	O/P	O/P[4]	**DSP SLAVE MODE.** This mode of operation is where the part provides a noncontinuous serial clock (SCLK with a total of 16 clock cycles) and the frame sync ($\overline{SYNC}$).
5 (AD7853 Only)	1	1	O/P[3]	I/P	O/P	O/P[5]	This another DSP slave mode of operation where the part provides a **CONTINUOUS CLOCK (TMS)** signal (SCLK) and frame sync output ($\overline{SYNC}$).

NOTES
I/P: Input, I/O: Input/Output, O/P: Output
[1]$\overline{SYNC}$ pin is an input pin which is level triggered active low.
[2]Output data may appear at the DOUT pin but the pin is not used and should be left unconnected.
[3]A frame sync signal (input or output) which is edge triggered (high to low).
[4]Noncontinuous serial clock.
[5]Continuous serial clock.

OPERATING SETUPS

From Table III it is clear that all the interface modes apply to the AD7853 (*and AD7853L*) but that only interface modes 1 and 2 apply to the AD7858 (*and AD7858L*). In all the timing diagrams the reference to the Polarity, SM1 and SM2 pins only applies to the AD7853. Next, before describing the operating modes in more detail, the different arrangements for reading, writing and starting conversions will be described.

The most useful arrangement is where the writing and reading takes place during conversion as shown in Figure 3. This allows for the maximum throughput rate (200 kHz AD7853/AD7858, 100 kHz AD7853L/AD7858L). It is clear from Figure 3 that the read on the DOUT pin is for the previous conversion and the write on the DIN pin is for the next conversion.

The arrangement in Figure 3 is only valid for the three-wire mode and the DSP Master Mode (AD7853 only) of operation. The different arrangements for the other modes of operation are shown under the respective operating mode section.

There are other less common arrangements that can be used. These involve initiating a write in synchronization with the start of conversion and then waiting for the conversion to be complete before reading from the part. The reverse of this can also be used where a read is initiated in synchronization with the start of conversion, and writing to the part once the conversion is complete. Alternatively the conversion can be initiated by setting the $\overline{CONVST}$ bit in the control register to 1 when writing to the part. These arrangements are similar to the arrangements shown in Figures 4c, 4d, and 4e for the two-wire mode of operation, but both the reading and writing would not take place on the DIN pin.

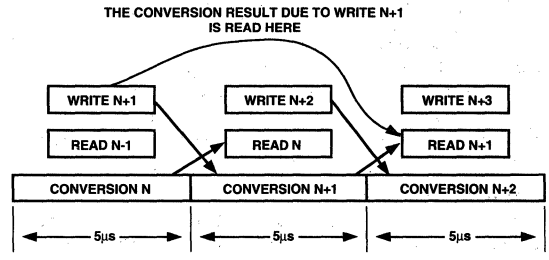


Figure 3.

Timing

The two timing figures t_3 and t_{10} need to be explained due to their complexity. Theses times apply to Figures 4d, 4e, 5a, 5b, and 6 only where the $\overline{SYNC}$ and the SCLK are both inputs to the part. For Figure 8 where $\overline{SYNC}$ and SCLK are outputs from the part, t_{3A} and t_{10A} are used and these are explained under the DSP Slave Mode section.

Taking t_3 first and a continuous SCLK situation (*which only applies for Figures 4d, 5a and 6*), t_3 has a minimum spec of 60 ns so that the part will have enough time to prepare for the first SCLK edge. The max spec for t_3 (*which only applies with a continuous SCLK*) is 0.4 t_{SCLK} which ensures that the $\overline{SYNC}$ does not go low before the rising edge A of the dashed SCLK (*shown in the timing diagrams*). This ensures that the part does not clock in an incorrect data bit from the DIN pin as DB15.

Next take the time t_{10} and a continuous SCLK situation (*again this only applies to Figures 4d, 5a and 6*), t_{10} has a minimum spec of 30 ns which is so that the part will have enough time to prepare for the rising edge of $\overline{SYNC}$. The max spec for t_{10} (*which only applies with a continuous SCLK*) is 0.4 t_{SCLK} which ensures that the SYNC goes high before the falling edge B of the dashed SCLK (*shown in the timing diagrams*). This ensures that the part does not offset the next write sequence and also so that an extra bit will not be clocked out onto the DOUT pin.

Both t_3 and t_{10} only have a minimum spec when there is a noncontinuous SCLK to allow the part enough time to prepare for the following edge of the relevant signal. There is no maximum spec for t_3 and t_{10} as there is no danger of getting an extra clock edge to upset the operation of the part.

Two-Wire Mode (AD7853 and AD7858)

The different setup arrangements for reading and writing to the part in the two-wire mode are shown in Figures 4a, 4b, and 4c. The read and writing takes place on the DIN line and the conversion start take place on the $\overline{CONVST}$ line. (Note that the write to the part must set the 2/$\overline{3}$ MODE bit in the control register to 1 for all cases 4a, 4b, 4c. Also the conversion can be started by setting the $\overline{CONVST}$ bit in the control register to 1, and so the $\overline{CONVST}$ pin does not need to be used in cases 4b and 4c.)

In Figure 4a a write is initiated in synchronization with the start of a conversion cycle (*thus with this setup the write cannot initiate the start of conversion via the control register, but the 2/$\overline{3}$ MODE bit must be set to 1 in all the write sequences to the part*). Then after the conversion is finished, a read operation is started and the data read here is from conversion N-1 and does not correspond to the previous write. You must wait until the next conversion (conversion N) before reading data corresponding to the initial write (write N). The very first read from the part here will not contain a result from a conversion under the two-wire mode due to the fact that the write sequence is one sequence behind the conversion sequence. The time for the read and write operation given is for a serial clock of 4 MHz (*2 MHz is max for L versions*), but is still only an approximate time. Thus the 9.5 µs shown is the fastest throughput time for the two-wire interface operating mode which corresponds to a frequency of 105 kHz (*52 kHz for L versions*).

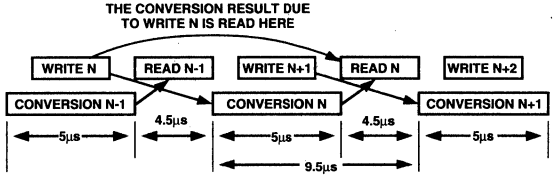

Figure 4a.

Figure 4b is the same as Figure 4a except that the conversion is initiated in synchronizations with a read operation instead of a write operation. Again the data read from the part is one conversion behind the corresponding write operation. (The *write to the part must enable the two-wire mode and may also initiate a conversion, and so the hardware* $\overline{CONVST}$ *signal is not needed.*)

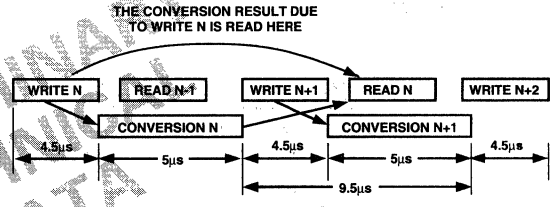

Figure 4b.

Figure 4c shows another way of operating the part in the two-wire mode where getting the fastest throughput rate is not essential. It is the most basic way to operate the part. A write is initiated (*which enables the two-wire mode and may also initiate the start of conversion*). After this a conversion is started, and when conversion is complete, the result is read back. From these diagrams it can be seen that the part cannot be run at its max throughput rate in the two-wire mode due to the time taken to read and write data on the same pin.

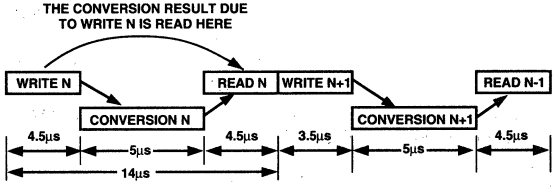

Figure 4c.

Below in Figure 4d and in Figure 4e are the timing diagrams for operating mode No. 1 in Table I where we are in the 2-wire interface mode. Here the DIN pin is used for both input and output as shown. The $\overline{SYNC}$ input is level triggered active low and can be pulsed (Figure 4d) or can be constantly low (Figure 4e).

In Figure 4a the part samples the input data on the rising edge of SCLK. When the $\overline{SYNC}$ is taken high, the DIN pin is configured as an output and is then 3-stated. Taking $\overline{SYNC}$ low disables the 3-state on the DIN pin, and the first SCLK falling edge clocks out the first data bit. Once the 16 clocks have been provided and the $\overline{SYNC}$ taken high, the DIN pin will automatically revert back to being an input after a time t_{11}. Note that a continuous SCLK shown by the dotted waveform in Figure 4d can be used provided that the $\overline{SYNC}$ is low for only 16 clock pulses in each of the read and write cycles.

In Figure 4e the $\overline{SYNC}$ line is tied low permanently, and this results in a different timing arrangement for the DIN pin. The difference between $\overline{SYNC}$ being tied low and being pulsed is that the DIN pin will never be 3-stated in this mode, and it is also the last rising edge of the SCLK that causes the DIN pin to go from being an input to an output and back to an input pin. Here a continuous SCLK cannot be used as the $\overline{SYNC}$ is tied low permanently.

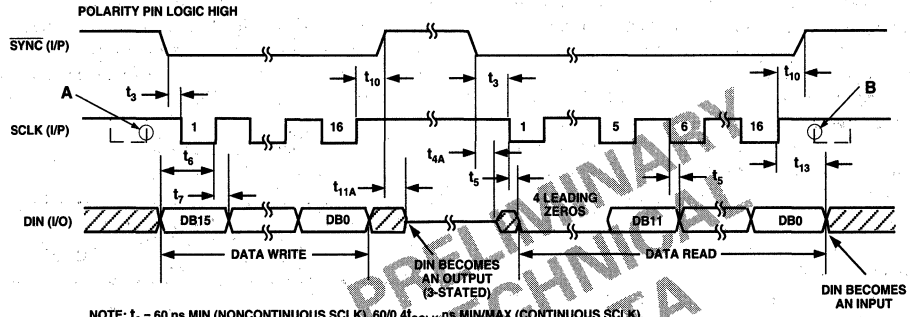

Figure 4d. Timing Diagram for Read/Write Operations with DIN as an Input/Output (i.e., Operating Mode No. 1, SM1 = SM2 = 0)

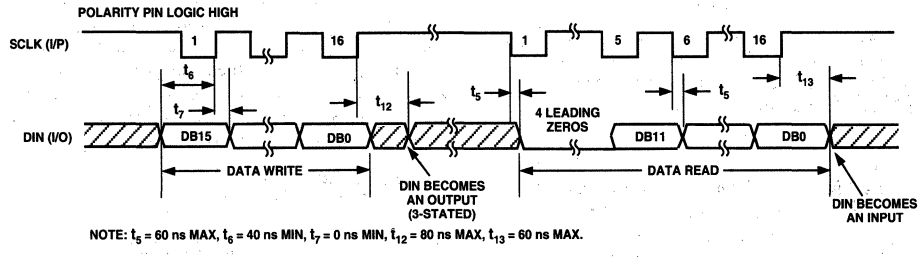

Figure 4e. Timing Diagram for Read/Write Operations with DIN as an Input/Output and $\overline{SYNC}$ Input Tied Low (i.e., Operating Mode No. 1, SM1 = SM2 = 0)

Three-Wire Mode (AD7853 and AD7858)

In Figure 5a and Figure 5b we have the timing diagrams for operating mode No. 2 in Table I which is the three-wire interface mode. Here the $\overline{SYNC}$ input is active low and can be pulsed (Figure 5a) or can be constantly low, (Figure 5b). If $\overline{SYNC}$ is constantly low, the serial clock input (SCLK) must supply 16 clock pulses for the part to operate correctly; otherwise with a pulsed $\overline{SYNC}$ input, a continuous SCLK can be used provided $\overline{SYNC}$ is low for only 16 clock cycles. In Figure 5a the $\overline{SYNC}$ going low disables the 3-state on the DOUT pin. The first falling edge of the SCLK after the $\overline{SYNC}$ going low clocks out the first leading zero on the DOUT pin. The DOUT pin is 3-stated again a time t_{11} after the $\overline{SYNC}$ goes high. With the DIN pin the data input has to be set up a time t_6 before the SCLK rising edge as the part samples the input data on the SCLK rising edge.

Figure 5b shows the timing diagram for the three-wire interface mode where the $\overline{SYNC}$ input has been tied permanently low. The only difference between this timing diagram and the one in Figure 5a is that the DOUT pin is never 3-stated since the $\overline{SYNC}$ input is never brought high. Also the LSB of the output data will remain on the DOUT pin until the next read cycle where the first SCLK falling edge will clock out the first leading zero of the next conversion.

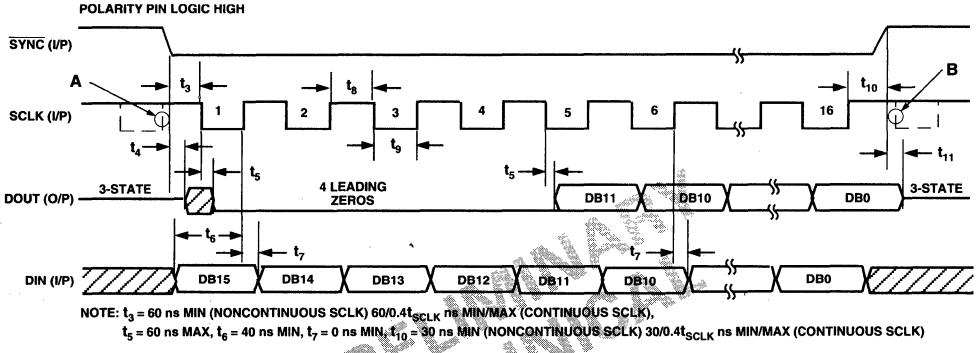

Figure 5a. Timing Diagram for Read/Write Operations with DIN as an Input and DOUT as Output and $\overline{SYNC}$ Input Pulsed (i.e., Operating Mode No. 2, SM1 = SM2 = 0)

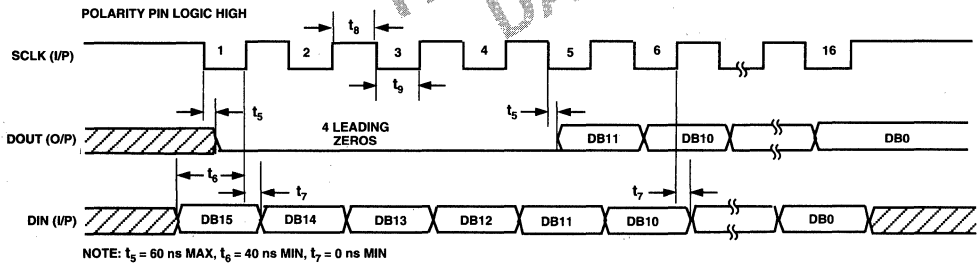

Figure 5b. Timing Diagram for Read/Write Operations with DIN as an Input and DOUT as Output and $\overline{SYNC}$ Input Tied Low (i.e., Operating Mode No. 2, SM1 = SM2 = 0)

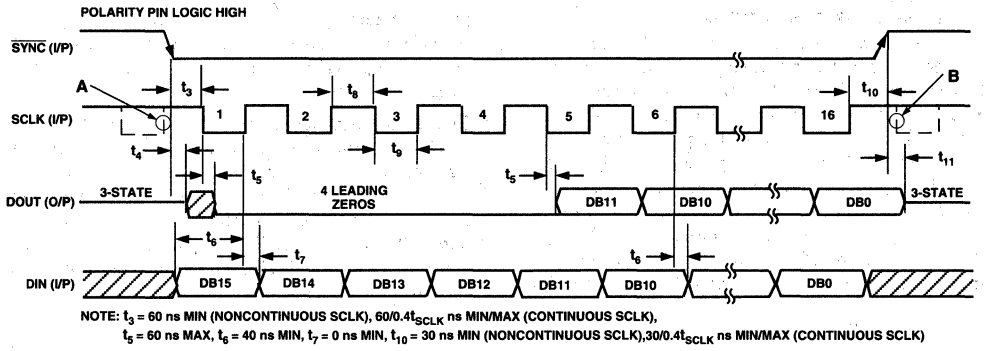

Figure 6. Timing Diagram for Read/Write Operation with $\overline{SYNC}$ Input Edge Triggered (i.e., Operating Mode No. 3, SM1 = 0 SM2 = 1)

DSP Master Mode (AD7853 Only)

In Figure 6 the timing diagram for operating mode No. 3 is shown. In this mode the DSP is the master and the part is the slave. Here the $\overline{SYNC}$ input is edge triggered going from high to low, and the 16 clock pulses are counted from this edge so that you can have a continuous clock input or a noncontinuous clock input that provides 16 clock pulses after the falling edge of the $\overline{SYNC}$ input. If a continuous clock is being used, the $\overline{SYNC}$ must go high after 16 clock pulses to disable the effect of any more clocks. The falling edge of $\overline{SYNC}$ disables the 3-state on the DOUT pin, and the data is clocked out on the falling edge of SCLK. Once $\overline{SYNC}$ goes high, the 3-state on the DOUT pin is enabled. The data input is sampled on the rising edge of SCLK and thus has to be valid a time t_6 before this rising edge.

DSP Slave Mode (AD7853 Only) (Continuous and Noncontinuous SCLK)

The timing diagram here is for operating mode Nos. 4 and 5, the only difference being the continuous and noncontinuous clock outputs. These modes of operation are especially different from all the other modes since the SCLK and $\overline{SYNC}$ are outputs. The $\overline{SYNC}$ is generated by the part as is the SCLK, and the dotted line shows the case of the continuous clock. The master clock at the CLKIN pin is routed directly to the SCLK pin for operating mode No. 5 (Continuous SCLK), and the CLKIN input is gated with the $\overline{SYNC}$ to give the SCLK in operating mode No. 4 (Noncontinuous SCLK).

The most important point about these two operation modes is that the result of the current conversion is clocked out during the same conversion, and a write to the part during this conversion is for the next conversion. The arrangement is shown in Figure 7. First the conversion is initiated with the $\overline{CONVST}$ signal going low, and then when part is ready, the $\overline{SYNC}$ will go low and the SCLK will clock out the data on the DOUT pin during conversion. Also the data on the DIN pin is clocked in by the same SCLK for the next conversion. All the timing waveforms in Figure 8 are during conversion. Thus in these two modes of operation the maximum throughput rate of 200 kHz (AD7853) and 100 kHz (AD7853L) can be obtained with the added advantage that the result read during conversion is the result of the current conversion and not the result of the previous as in the other modes of operation.

In these modes the part is now the master and the DSP is the slave. The output data is clocked out from the part to the DOUT pin on the rising edge of SCLK, and the input data to the part on the DIN pin is also clocked in to the part on the rising edge of the SCLK.

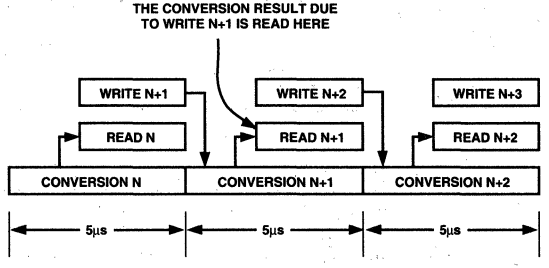

Figure 7.

Some of the timing numbers for the timing diagram of Figure 8 need explaining due to their complexity. First, t_{3A} has only a min spec and no max spec as the part will ensure that the $\overline{SYNC}$

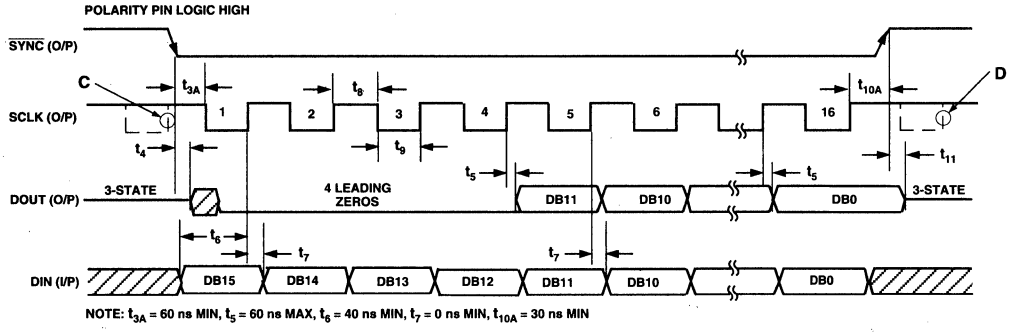

Figure 8. Timing Diagram for Read/Write with $\overline{SYNC}$ Output and SCLK Output (Continuous and Noncontinuous) (i.e., Operating Mode Nos. 4 and 5, SM1 = 1, SM2 = 1 and 0)

goes low after the rising edge C of the dashed SCLK in Figure 8 (if there is a continuous SCLK) so that the part will not clock in an incorrect data bit from the DIN pin as DB15. The other time is t_{10A} which again only has a min spec and no max spec as the part will again ensure that the SYNC has gone high before the rising edge D of the dashed SCLK in Figure 8 (if there is a continuous SCLK). This ensures both that the SCLK will not clock in an extra bit from the DIN pin which would offset the next write sequence, and also that another bit will not be clocked out of the part onto the DOUT pin.

CALIBRATION

There are two main calibration features on the AD7853/AD7858; these are a self or device calibration and a system calibration. For both system and self-calibrations there are a number of different types of calibration that can be selected depending on the setting of various bits in the control register. These options are covered by Table I.

There are a number of points that are useful to state before describing the procedure for initiating a system calibration. The first point is that the maximum calibration range is approximately ±3% of V_{REF} for both the system offset and gain errors. Also, if the errors are outside this range, the system calibration algorithm will reduce the errors as much as the trim range allows. Large system errors can be reduced in an incremental fashion by doing multiple system (gain + offset) calibrations. This is possible due to the way that the system calibration algorithm works. In bipolar mode (*AD7853 only*) it is the midscale error and the positive full-scale error that are adjusted; in unipolar mode it is the zero-scale error and the positive full-scale error that are adjusted.

System Calibration

The calibration timing diagram in Figure 9 is for a system calibration where the falling edge of $\overline{CAL}$ initiates an internal reset before starting a calibration. (*Note that if the part is in the autoshut-off mode where BUSY is connected to $\overline{SLEEP}$ so that the part goes into sleep mode after conversion, then t_1 will be as for the $\overline{CONVST}$ to allow for the "wake-up" time; again depending on the type of sleep mode that the part is in, there will be different "wake-up" times.*) Then the rising edge of $\overline{CAL}$ starts calibration of the internal DAC. Then if the control register is set for a full calibration, the $\overline{CONVST}$ must be used also. The full-scale system voltage should be applied to the analog input pins from the start of calibration. Then the offset voltage due to the system must be present on the AIN pin (after the full-scale system offset is completed) for a minimum setup time (t_{SETUP}) of 100 ns before the rising edge of the $\overline{CONVST}$.

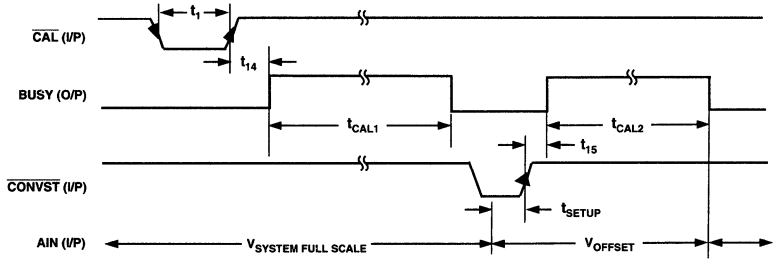

Figure 9. Calibration Timing Diagram for Full System Calibration

Self-Calibration

For a self or device calibration the procedure is similar to that of the calibration timing diagram of Figure 9, but the BUSY line will stay high for the full length of the self-calibration and will not pulse like in the system calibration diagram. So a self-calibration is initiated by bringing the $\overline{CAL}$ pin low (which initiates an internal reset as in system calibration) and then high again. (*Note that if the part is in the autoshut-off mode where BUSY is connected to* $\overline{SLEEP}$ *so that the part goes into sleep mode after conversion, then* t_1 *will be as for the* $\overline{CONVST}$ *to allow for the "wake-up" time; again depending on the type of sleep mode that the part is in, there will be different "wake-up" times.*) The BUSY line is triggered high from the rising edge of $\overline{CAL}$ and BUSY will go low when the self-calibration is complete.

POWER-DOWN MODES

There are two power-down modes on the part, one being a full power down, the other a selective power down where only certain internal circuitry is powered down. The advantage of the selective power down is that the part will not require as much time to "wake up" as for the full power down. The type of power down is selected by programming the power management bit (PMGT) in the control register, 0 for a full power down and 1 for a selective power down.

There is an automatic power-down mode which is achieved by connecting the BUSY pin to the SLEEP pin where the part goes into power-down mode after the end of conversion. Again the power management bit (PMGT) in the control register determines whether this is a full or selective power down. With this setup the part will take longer to "wake-up" than in the normal mode, and this time will also depend on the capacitor connected to the C_{REF} pins. Table IV contains power-up times for different values of capacitors connected to the C_{REF} pins and for the two different power-down modes (full power down or selective power down).

Table IV.

C_{REF1} (μF)	C_{REF2} (μF)	Power-Down Mode	Power-Up Delay (sec)
0.1	0.01	Full	TBD
0.1	0.01	Selective	TBD
1.0	0.1	Full	TBD
1.0	0.1	Selective	TBD

ANALOG DEVICES

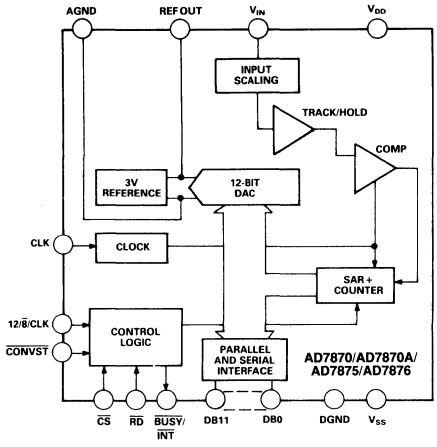
LC²MOS
Complete, 12-Bit, 100 kHz, Sampling ADCs
AD7870/AD7870A/AD7875/AD7876

FEATURES

Complete Monolithic 12-Bit ADC with:
- **2 μs Track/Hold Amplifier**
- **8 μs A/D Converter**
- **On-Chip Reference**
- **Laser-Trimmed Clock**
- **Parallel, Byte and Serial Digital Interface**

72 dB SNR at 10 kHz Input Frequency (AD7870, AD7870A, AD7875)
57 ns Data Access Time
Low Power −60 mW typ
Variety of Input Ranges:
- **±3 V for AD7870/AD7870A**
- **0 to +5 V for AD7875**
- **±10 V for AD7876**

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7870/AD7870A/AD7875/AD7876 is a fast, complete, 12-bit A/D converter. It consists of a track/hold amplifier, 8 μs successive-approximation ADC, 3 V buried Zener reference and versatile interface logic. The ADC features a self-contained internal clock which is laser trimmed to guarantee accurate control of conversion time. No external clock timing components are required; the on-chip clock may be overridden by an external clock if required.

The parts offer a choice of three data output formats: a single, parallel, 12-bit word; two 8-bit bytes, or serial data. Fast bus access times and standard control inputs ensure easy interfacing to modern microprocessors and digital signal processors.

All parts operate from ±5 V power supplies. The AD7870 and AD7876 accept input signal ranges of ±3 V and ±10 V, respectively, while the AD7875 accepts a unipolar 0 to +5 V input range. The parts can convert full power signals up to 50 kHz.

The AD7870/AD7870A/AD7875/AD7876 feature dc accuracy specifications such as linearity, full-scale and offset error. In addition, the AD7870/AD7870A and AD7875 are fully specified for dynamic performance parameters including distortion and signal-to-noise ratio.

The parts are fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low-power CMOS logic. The parts are available in a 24-pin, 0.3 inch-wide, plastic or hermetic dual-in-line package (DIP). The AD7870/AD7870A and AD7875 are available in a 28-pin plastic leaded chip carrier (PLCC), while the AD7876 is available and in a 24-pin small outline (SOIC) package.

PRODUCT HIGHLIGHTS

1. Complete 12-Bit ADC on a Chip.
   The AD7870/AD7870A/AD7875/AD7876 provides all the functions necessary for analog-to-digital conversion and combines a 12-bit ADC with internal clock, track/hold amplifier and reference on a single chip.
2. Dynamic Specifications for DSP Users.
   The AD7870/AD7870A and AD7875 are fully specified and tested for ac parameters, including signal-to-noise ratio, harmonic distortion and intermodulation distortion.
3. Fast Microprocessor Interface.
   Data access times of 57 ns make the parts compatible with modern 8- and 16-bit microprocessors and digital signal processors. Key digital timing parameters are tested and guaranteed over the full operating temperature range.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

t_{11}[5]	370	370	ns min	SCLK Cycle Time
t_{12}[6]	135	150	ns max	SCLK to Valid Data Delay. C_L=35 pF
t_{13}	20	20	ns min	SCLK Rising Edge to $\overline{SSTRB}$
	100	100	ns max	
t_{14}	10	10	ns min	Bus Relinquish Time after SCLK
	100	100	ns max	
t_{15}	60	60	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time (Mode 2)
t_{16}	120	120	ns max	$\overline{CS}$ to $\overline{BUSY}$ Propagation Delay
t_{17}	200	200	ns min	Data Setup Time Prior to $\overline{BUSY}$
t_{18}	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time (Mode 2)
t_{19}	0	0	ns min	HBEN to $\overline{CS}$ Setup Time
t_{20}	0	0	ns min	HBEN to $\overline{CS}$ Hold Time

NOTES

[1]Timing specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on SDATA and $\overline{SSTRB}$ and a 2 kΩ pull-up on SCLK. The capacitance on all three outputs is 35 pF.

[3]t_6 is measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[4]t_7 is defined as the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.

[5]SCLK mark/space ratio (measured from a voltage level of 1.6 V) is 40/60 to 60/40.

[6]SDATA will drive higher capacitive loads but this will add to t_{12} since it increases the external RC time constant (4.7 kΩ||C_L) and hence the time to reach 2.4 V. Specifications subject to change without notice.

Figure 2. Load Circuits for Output Float Delay

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN FUNCTION DESCRIPTION

DIP Pin No.	Pin Mnemonic	Function
1	$\overline{RD}$	Read. Active low logic input. This input is used in conjunction with $\overline{CS}$ low to enable the data outputs.
2	$\overline{BUSY/INT}$	Busy/Interrupt, Active low logic output indicating converter status. See timing diagrams.
3	CLK	Clock input. An external TTL-compatible clock may be applied to this input pin. Alternatively, tying this pin to V_{SS} enables the internal laser-trimmed clock oscillator.
4	DB11/HBEN	Data Bit 11 (MSB)/High Byte Enable. The function of this pin is dependent on the state of the 12/$\overline{8}$/CLK input (see below). When 12-bit parallel data is selected, this pin provides the DB11 output. When byte data is selected, this pin becomes the HBEN logic input. HBEN is used for 8-bit bus interfacing. When HBEN is low, DB7/LOW to DB0/DB8 become DB7 to DB0. With HBEN high, DB7/LOW to DB0/DB8 are used for the upper byte of data (see Table I).
5	DB10/$\overline{SSTRB}$	Data Bit 10/Serial Strobe. When 12-bit parallel data is selected, this pin provides the DB10 output. $\overline{SSTRB}$ is an active low open-drain output that provides a strobe or framing pulse for serial data. An external 4.7 kΩ pull-up resistor is required on $\overline{SSTRB}$.
6	DB9/SCLK	Data Bit 9/Serial Clock. When 12-bit parallel data is selected, this pin provides the DB9 output. SCLK is the gated serial clock output derived from the internal or external ADC clock. If the 12/$\overline{8}$/CLK input is at −5 V, then SCLK runs continuously. If 12/$\overline{8}$/CLK is at 0 V, then SCLK is gated off after serial transmission is complete. SCLK is an open-drain output and requires an external 2 kΩ pull-up resistor.
7	DB8/SDATA	Data Bit 8/Serial Data. When 12-bit parallel data is selected, this pin provides the DB8 output. SDATA is an open-drain serial data output which is used with SCLK and $\overline{SSTRB}$ for serial data transfer. Serial data is valid on the falling edge of SCLK while $\overline{SSTRB}$ is low. An external 4.7 kΩ pull-up resistor is required on SDATA.
8–11	DB7/LOW–DB4/LOW	Three-state data outputs which are controlled by $\overline{CS}$ and $\overline{RD}$. Their function depends on the 12/$\overline{8}$/CLK and HBEN inputs. With 12/$\overline{8}$/CLK high, they are always DB7-DB4. With 12/$\overline{8}$/CLK low or −5 V, their function is controlled by HBEN (see Table I).
12	DGND	Digital Ground. Ground reference for digital circuitry.
13–16	DB3/DB11–DB0/DB8	Three-state data outputs which are controlled by $\overline{CS}$ and $\overline{RD}$. Their function depends on the 12/$\overline{8}$/CLK and HBEN inputs. With/12/$\overline{8}$/CLK high, they are always DB3-DB0. With 12/$\overline{8}$/CLK low or −5 V, their function is controlled by HBEN (see Table I).
17	V_{DD}	Positive Supply, +5 V ±5%.
18	AGND	Analog Ground. Ground reference for track/hold, reference and DAC.
19	REF OUT	Voltage Reference Output. The internal 3 V reference is provided at this pin. The external load capability is 500 μA.
20	V_{IN}	Analog Input. The analog input range is ±3 V for the AD7870, ±10 V for the AD7876 and 0 to +5 V for the AD7875.
21	V_{SS}	Negative Supply, −5 V ±5%.
22	12/$\overline{8}$/CLK	Three Function Input. Defines the data format and serial clock format. With this pin at +5 V, the output data format is 12-bit parallel only. With this pin at 0 V, either byte or serial data is available and SCLK is not continuous. With this pin at −5 V, byte or serial data is again available but SCLK is now continuous.
23	$\overline{CONVST}$	Convert Start. A low to high transition on this input puts the track/hold into its hold mode and starts conversion. This input is asynchronous to the CLK input.
24	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active. With $\overline{CONVST}$ tied low, a new conversion is initiated when $\overline{CS}$ goes low.

HBEN	DB7/LOW	DB6/LOW	DB5/LOW	DB4/LOW	DB3/DB11	DB2/DB10	DB1/DB9	DB0/DB8
HIGH	LOW	LOW	LOW	LOW	DB11 (MSB)	DB10	DB9	DB8
LOW	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0 (LSB)

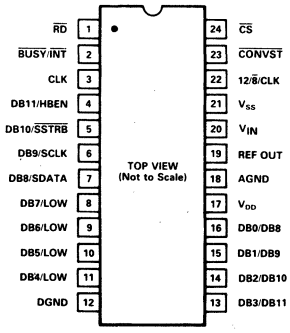
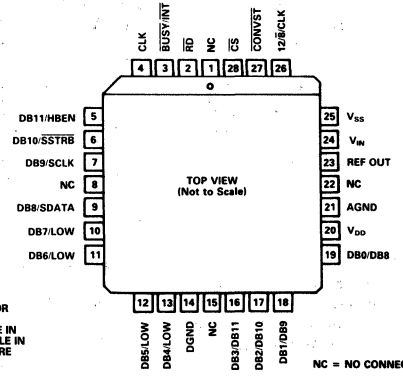
PIN CONFIGURATIONS[1]

DIP and SOIC[2]



PLCC[2]



[1]PIN CONFIGURATIONS ARE THE SAME FOR THE AD7870, AD7875 AND AD7876.
[2]THE AD7870 AND AD7875 ARE AVAILABLE IN DIP AND PLCC; THE AD7870A IS AVAILABLE IN PLASTIC DIP; THE AD7875 AND AD7876 ARE AVAILABLE IN SOIC AND DIP.

LC²MOS Complete 14-Bit Sampling ADCs

AD7871/AD7872

FEATURES

Complete Monolithic 14-Bit ADC
2s Complement Coding
Parallel, Byte and Serial Digital Interface
80 dB SNR at 10 kHz Input Frequency
57 ns Data Access Time
Low Power—50 mW typ
83 kSPS Throughput Rate
16-Lead SOIC (AD7872)

APPLICATIONS

Digital Signal Processing
High Speed Modems
Speech Recognition and Synthesis
Spectrum Analysis
DSP Servo Control

GENERAL DESCRIPTION

The AD7871 and AD7872 are fast, complete, 14-bit analog-to-digital converters. They consist of a track/hold amplifier, successive-approximation ADC, 3 V buried Zener reference and versatile interface logic. The ADC features a self-contained, laser trimmed internal clock, so no external clock timing components are required. The on-chip clock may be overridden to synchronize ADC operation to the digital system for minimum noise.

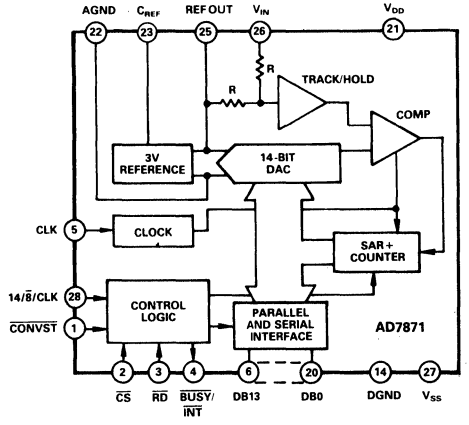
The AD7871 offers a choice of three data output formats: a single, parallel, 14-bit word; two 8-bit bytes or a 14-bit serial data stream. The AD7872 is a serial output device only. The two parts are capable of interfacing to all modern microprocessors and digital signal processors.

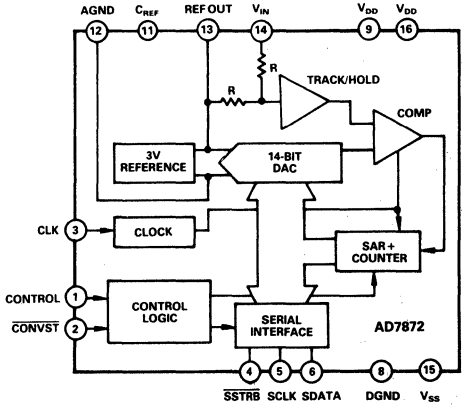
The AD7871 and AD7872 operate from ±5 V power supplies, accept bipolar input signals of ±3 V and can convert full power signals up to 41.5 kHz.

In addition to the traditional dc accuracy specifications, the AD7871 and AD7872 are also fully specified for dynamic performance parameters including distortion and signal-to-noise ratio.

Both devices are fabricated in Analog Devices' LC²MOS mixed technology process. The AD7871 is available in 28-pin plastic DIP, hermetic DIP and PLCC packages. The AD7872 is available in 16-pin plastic and hermetic DIP packages or 16-lead SOIC.

FUNCTIONAL BLOCK DIAGRAMS





PRODUCT HIGHLIGHTS

1. Complete 14-Bit ADC on a Chip.
2. Dynamic Specifications for DSP Users.
3. Low Power.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7871/AD7872—SPECIFICATIONS

(V_{DD} = +5 V ± 5%, V_{SS} = −5 V ± 5%, AGND = DGND = 0 V, f_{CLK} = 2 MHz external, f_{SAMPLE} = 83 kHz unless otherwise stated.)All Specifications T_{min} to T_{max} unless otherwise noted.

Parameter	J, A Versions[1]	K, B Versions[1]	T Version[1]	Units	Test Conditions/Comments
DYNAMIC PERFORMANCE[2]					
Signal to Noise Ratio[3] (SNR) @ +25°C	80	80	79	dB min	V_{IN} = 10 kHz Sine Wave
T_{min} to T_{max}	80	80	79	dB min	SNR is Typically 82 dB for $<V_{IN}<$41.5 kHz;
Total Harmonic Distortion (THD)	−86	−90		dB max	V_{IN} = 10 kHz Sine Wave;
			−85	dB typ	
Peak Harmonic or Spurious Noise	−86	−90		dB max	V_{IN} = 10 kHz.
			−85	dB typ	
Intermodulation Distortion (IMD)					
Second Order Terms	−86	−90		dB max	fa = 9 kHz, fb = 9.5 kHz, f_{SAMPLE} = 50 kHz
			−85	dB typ	
Third Order Terms	−86	−90		dB max	fa = 9 kHz, fb = 9.5 kHz, f_{SAMPLE} = 50 kHz
			−85	dB typ	
Track/Hold Acquisition Time	2	2	2	μs max	
DC ACCURACY					
Resolution	14	14	14	Bits	
Minimum Resolution for Which					
No Missing Codes Are Guaranteed	14	14	14	Bits	
Integral Nonlinearity @ +25°C		±1/2	±1/2	LSB typ	
Integral Nonlinearity		±1	±1	LSB max	
Bipolar Zero Error	±12	±12	±12	LSB max	
Positive Gain Error[4]	±12	±12	±12	LSB max	
Negative Gain Error[4]	±12	±12	±12	LSB max	
ANALOG INPUT					
Input Voltage Range	±3	±3	±3	Volts	
Input Current	±500	±500	±500	μA max	
REFERENCE OUTPUT					
REF OUT @ +25°C	2.99/3.01	2.99/3.01	2.99/3.01	V min/V max	
T_{min} to T_{max}	2.98/3.02	2.98/3.02	2.98/3.02	V min/V max	
REF OUT Tempco		±40	±40	ppm/°C max	Typically 35 ppm
Reference Load Sensitivity					
(ΔREF OUT/ΔI)	±1	±1	±1	mV max	Reference Load Current Change (0–500 μA); Reference Load Should Not Be Changed During Conversion
LOGIC INPUTS					
Input High Voltage, V_{INH}	2.4	2.4	2.4	V min	V_{DD} = 5 V ± 5%
Input Low Voltage, V_{INL}	0.8	0.8	0.8	V max	V_{DD} = 5 V ± 5%
Input Current, $I_{IN\_}$	±10	±10	±10	μA max	V_{IN} = 0 V to V_{DD}
Input Current (14/8/CLK Input Only)	±10	±10	±10	μA max	V_{IN} = V_{SS} to V_{DD}
Input Capacitance, C_{IN}[5]	10	10	10	pF max	
LOGIC OUTPUTS					
Output High Voltage, V_{OH}	4.0	4.0	4.0	V min	I_{SOURCE} = 40 μA
Output Low Voltage, V_{OL}	0.4	0.4	0.4	V max	I_{SINK} = 1.6 mA
DB13 – DB0					
Floating-State Leakage Current	10	10	10	μA max	
Floating-State Output Capacitance[5]	15	15	15	pF max	
CONVERSION TIME					
External Clock	10	10	10	μs max	
Internal Clock	10.5	10.5	10.5	μs max	The Internal Clock Has a Nominal Value of 2 MHz
POWER REQUIREMENTS					
V_{DD}	+5	+5	+5	V nom	±5% for Specified Performance
V_{SS}	−5	−5	−5	V nom	±5% for Specified Performance
I_{DD}	13	13	13	mA max	Typically 6 mA
I_{SS}	6	6	6	mA max	Typically 4 mA
Power Dissipation	95	95	95	mW max	Typically 50 mW

NOTES

[1]Temperature ranges are as follows: J, K versions, 0°C to +70°C; A, B versions, −40°C to +85°C; T version; −55°C to +125°C.

[2]V_{IN} = ±3 V.

[3]SNR calculation includes distortion and noise components.

[4]Measured with respect to internal reference.

[5]Sample tested @ +25°C to ensure compliance.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1, 2] (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ± 5%, AGND = DGND = 0 V. See Figures 3, 4, 5 and 6.)

Parameter	Limit at T_{min}, T_{max} (J, K, A, B Versions)	Limit at T_{min}, T_{max} (T Version)	Units	Conditions/Comments
t_1	50	50	ns min	$\overline{CONVST}$ Pulse Width

t_{11}[5]	440	440	ns min	SCLK Cycle Time
t_{12}[6]	155	155	ns max	SCLK to Valid Data Delay. C_L = 35 pF
t_{13}	140	150	ns max	SCLK Rising Edge to $\overline{SSTRB}$
	20	20	ns min	
t_{14}	4	4	ns min	Bus Relinquish Time after SCLK
	100	100	ns max	
t_{15}	60	60	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time (Mode 2)
t_{16}	120	120	ns max	$\overline{CS}$ to $\overline{BUSY}$ Propagation Delay
t_{17}[3]	200	200	ns min	Data Setup Time Prior to BUSY
t_{18}	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time (Mode 2)
t_{19}	0	0	ns min	HBEN to $\overline{CS}$ Setup Time
t_{20}	0	0	ns min	HBEN to $\overline{CS}$ Hold Time

NOTES
[1]Timing Specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on SDATA and $\overline{SSTRB}$ and a 2 kΩ pull-up resistor on SCLK. The capacitance on all three outputs is 35 pF.
[3]t_6 and t_{17} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[4]t_7 is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 2. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the time, t_7, quoted in the Timing Characteristics is the true bus relinquish time of the part and is independent of bus loading.
[5]SCLK mark/space ratio (measured from a voltage level of 1.6 V) is 40/60 to 60/40.
[6]SDATA will drive higher capacitive loads, but this will add to t_{12} since it increases the external RC time constant (4.7 kΩ//C_L) and hence the time to reach 2.4 V.
Specifications subject to change without notice.

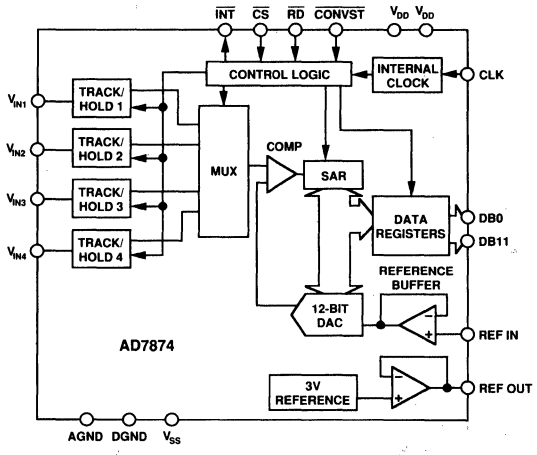
LC²MOS 4-Channel, 12-Bit Simultaneous Sampling Data Acquisition System

AD7874

FEATURES
Four On-Chip Track/Hold Amplifiers
Simultaneous Sampling of 4 Channels
Fast 12-Bit ADC with 8 μs Conversion Time/Channel
29 kHz Sample Rate for All Four Channels
On-Chip Reference
±10 V Input Range
±5 V Supplies

APPLICATIONS
Sonar
Motor Controllers
Adaptive Filters
Digital Signal Processing

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7874 is a four-channel simultaneous sampling, 12-bit data acquisition system. The part contains a high speed 12-bit ADC, on-chip reference, on-chip clock and four track/hold amplifiers. This latter feature allows the four input channels to be sampled simultaneously, thus preserving the relative phase information of the four input channels, which is not possible if all four channels share a single track/hold amplifier. This makes the AD7874 ideal for applications such as phased-array sonar and ac motor controllers where the relative phase information is important.

The aperture delay of the four track/hold amplifiers is small and specified with minimum and maximum limits. This allows several AD7874s to sample multiple input channels simultaneously without incurring phase errors between signals connected to several devices. A reference output/reference input facility also allows several AD7874s to be driven from the same reference source.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7874 is also fully specified for dynamic performance parameters including distortion and signal-to-noise ratio.

The AD7874 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low-power CMOS logic. The part is available in a 28-pin, 0.6″ wide, plastic or hermetic dual-in-line package (DIP), in a 28-terminal leadless ceramic chip carrier (LCCC) and in a 28-pin SOIC.

PRODUCT HIGHLIGHTS

1. Simultaneous Sampling of Four Input Channels.
   Four input channels, each with its own track/hold amplifier, allow simultaneous sampling of input signals. Track/hold acquisition time is 2 μs, and the conversion time per channel is 8 μs, allowing 29 kHz sample rate for all four channels.
2. Tight Aperture Delay Matching.
   The aperture delay for each channel is small and the aperture delay matching between the four channels is less than 4 ns. Additionally, the aperture delay specification has upper and lower limits allowing multiple AD7874s to sample more than four channels.
3. Fast Microprocessor Interface.
   The high speed digital interface of the AD7874 allows direct connection to all modern 16-bit microprocessors and digital signal processors.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

t_{CLK}	10	10	µs max	Minimum Input Clock Period

NOTES

[1]Timing Specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.

[2]t_6 is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_7 is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 2. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the time, t_7, quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

Specifications subject to change without notice.

Derates above +75°C by . . . . . 10 mW/°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

LC²MOS Complete 12-Bit 100 kHz Sampling ADC with DSP Interface

AD7878

FEATURES

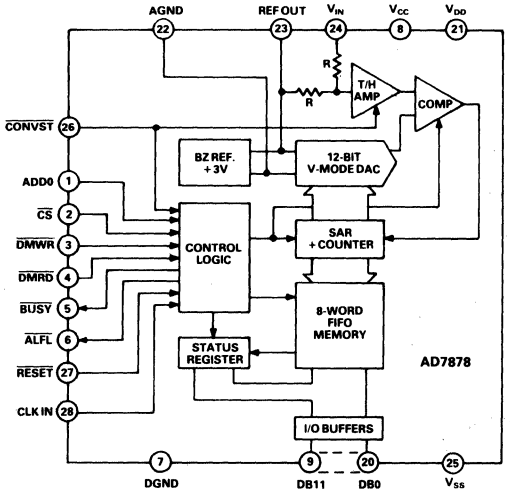
Complete ADC with DSP Interface, Comprising:
- **Track/Hold Amplifier with 2 µs Acquisition Time**
- **7 µs A/D Converter**
- **3 V Zener Reference**
- **8-Word FIFO and Interface Logic**

72 dB SNR at 10 kHz Input Frequency
Interfaces to High Speed DSP Processors, e.g., ADSP-2100, TMS32010, TMS32020
41 ns max Data Access Time
Low Power, 60 mW typ

APPLICATIONS

Digital Signal Processing
Speech Recognition and Synthesis
Spectrum Analysis
High Speed Modems
DSP Servo Control

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7878 is a fast, complete 12-bit A/D converter with a versatile DSP interface consisting of an 8-word, first-in, first-out (FIFO) memory and associated control logic.

The FIFO memory allows up to eight samples to be digitized before the microprocessor is required to service the A/D converter. The eight words can then be read out of the FIFO at maximum microprocessor speed. A fast data access time of 41 ns allows direct interfacing to DSP processors and high speed 16-bit microprocessors.

An on-chip status/control register allows the user to program the effective length of the FIFO and contains the FIFO out of range, FIFO empty and FIFO word count information.

The analog input of the AD7878 has a bipolar range of ±3 V. The AD7878 can convert full power signals up to 50 kHz and is fully specified for dynamic parameters such as signal-to-noise ratio and harmonic distortion.

The AD7878 is fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in four package styles, 28-pin plastic and hermetic dual-in-line package (DIP), leadless ceramic chip carrier (LCCC) or plastic leaded chip carrier (PLCC).

PRODUCT HIGHLIGHTS

1. Complete A/D Function with DSP Interface
   The AD7878 provides the complete function for digitizing ac signals to 12-bit accuracy. The part features an on-chip track/hold, on-chip reference and 12-bit A/D converter. The additional feature of an 8-word FIFO reduces the high software overheads associated with servicing interrupts in DSP processors.
2. Dynamic Specifications for DSP Users
   The AD7878 is fully specified and tested for ac parameters, including signal-to-noise ratio, harmonic distortion and intermodulation distortion. Key digital timing parameters are also tested and specified over the full operating temperature range.
3. Fast Microprocessor Interface
   Data access time of 41 ns is the fastest ever achieved in a monolithic A/D converter and makes the AD7878 compatible with all modern 16-bit microprocessors and digital signal processors.

t_{RESET}	2 CLK IN cycles	2 CLK IN cycles	2 CLK IN cycles	min	RESET Pulse Width

NOTES
[1]Timing Specifications in **bold** print are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]t_9 and t_{14} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[3]t_{10} is defined as the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

Pin Number	Pin Mnemonic	Function
1	ADD0	Address Input. This control input determines whether the word placed on the output data bus during a read operation is a data word from the FIFO RAM or the contents of the status/control register. A logic low accesses the data word from Location 0 of the FIFO while a logic high selects the contents of the register (see Status/Control Register section).
2	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active.
3	$\overline{DMWR}$	Data Memory Write. Active low logic input. $\overline{DMWR}$ is used in conjunction with $\overline{CS}$ low and ADD0 high to write data to the status/control register. Corresponds to $\overline{DMWR}$ (ADSP-2100), R/$\overline{W}$ (MC68000, TMS32020), $\overline{WE}$ (TMS32010).
4	$\overline{DMRD}$	Data Memory READ. Active low logic input. $\overline{DMRD}$ is used in conjunction with $\overline{CS}$ low to enable the three-state output buffers. Corresponds directly to $\overline{DMRD}$ (ADSP-2100), $\overline{DEN}$ (TMS32010).
5	$\overline{BUSY}$	Active low logic output. This output goes low when the ADC receives a $\overline{CONVST}$ pulse and remains low until the track/hold has gone into its hold mode. The three-state drivers of the AD7878 can be disabled while the $\overline{BUSY}$ signal is low (see Extended READ/WRITE section). This is achieved by writing a logic 0 to DB5 ($\overline{DISO}$) of the status/control register. Writing a logic 1 to DB5 of the status/control register allows data to be accessed from the AD7878 while $\overline{BUSY}$ is low.
6	$\overline{ALFL}$	FIFO Almost Full. A logic low indicates that the word count (i.e., number of conversion results) in the FIFO memory has reached the programmed word count in the status/control register. $\overline{ALFL}$ is updated at the end of each conversion. The $\overline{ALFL}$ output is reset to a logic high when a word is read from the FIFO memory and the word count is less than the preprogrammed word count. It can also be set high by writing a logic 1 to DB7 ($\overline{ENAF}$) of the status/control register.
7	DGND	Digital Ground. Ground reference for digital circuitry.
8	V_{CC}	Digital supply voltage, +5 V ±5%. Positive supply voltage for digital circuitry.
9	DB11	Data Bit 11 (MSB). Three-state TTL output. Coding for the data words in FIFO RAM is 2s complement.
10–15	DB10–DB5	Data Bit 10 to Data Bit 5. Three-state TTL input/outputs.
16–19	DB4–DB1	Data Bit 4 to Data Bit 1. Three-state TTL outputs.
20	DB0	Data Bit 0 (LSB). Three-state TTL output.
21	V_{DD}	Analog positive supply voltage, +5 V ±5%.
22	AGND	Analog Ground. Ground reference for track/hold, reference and DAC.
23	REF OUT	Voltage Reference Output. The internal 3 V analog reference is provided at this pin. The external load capability of the reference is 500 μA.
24	V_{IN}	Analog Input. Analog input range is ±3 V.
25	V_{SS}	Analog negative supply voltage, −5 V ±5%.
26	$\overline{CONVST}$	Convert Start. Logic input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion. The $\overline{CONVST}$ input is asynchronous to CLK IN and is independent of $\overline{CS}$, $\overline{DMWR}$ and $\overline{DMRD}$.
27	$\overline{RESET}$	Reset. Active low logic input. A logic low sets the words in FIFO memory to 1000 0000 0000 and resets the $\overline{ALFL}$ output and status/control register.
28	CLK IN	Clock Input. TTL-compatible logic input. Used as the clock source for the A/D converter. The mark-space ratio of this clock can vary from 35/65 to 65/35.

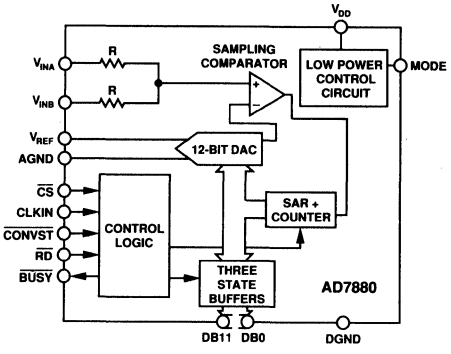
High Speed Modems
Control and Instrumentation

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7880 is a high speed, low power, 12-bit A/D converter which operates from a single +5 V supply. It consists of a 3 μs track/hold amplifier, a 12 μs successive-approximation ADC, versatile interface logic and a multiple-input-range circuit. The part also includes a power save feature.

An internal resistor network allows the part to accept both unipolar and bipolar input signals while operating from a single +5 V supply. Fast bus access times and standard control inputs ensure easy interfacing to modern microprocessors and digital signal processors.

The AD7880 features a total throughput time of 15 μs and can convert full power signals up to 33 kHz with a sampling frequency of 66 kHz.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7880 is also fully specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The AD7880 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin, 0.3 inch-wide, plastic or hermetic dual-in-line package (DIP) as well as a small 24-lead SOIC package.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time.
   12 μs conversion time and 3 μs acquisition time allow for large input signal bandwidth. This performance is ideally suited for applications in areas such as telecommunications, audio, sonar and radar signal processing.
2. Low Power Consumption.
   2 mW power consumption in the power-down mode makes the part ideally suited for portable, hand held, battery powered applications.
3. Multiple Input Ranges.
   The part features three user-determined input ranges, 0 to +5 V, 0 to 10 V and ±5 V. These unipolar and bipolar ranges are achieved with a 5 V only power supply.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

t_4	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time
t_5	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time
t_6	**60**	75	ns min	$\overline{RD}$ Pulse Width
t_7[2]	57	70	ns max	Data Access Time after $\overline{RD}$
t_8[3]	5	5	ns min	Bus Relinquish Time after $\overline{RD}$
	50	50	ns max	

NOTES

[1]Timing specifications in **bold** print are 100% production tested. All other times are sample tested at 25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]t_7 is measured with the load circuit of Figure 2 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_8 is derived from the measured time taken by the data outputs to change by 0.5 V when loaded with the circuit of Figure 2. The measured number is then extrapolated back to remove the effects of charging the 50 pF capacitor. This means that the time, t_8, quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

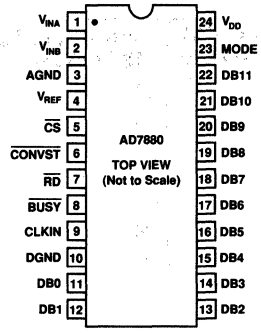
PIN CONFIGURATION



PIN FUNCTION DESCRIPTION

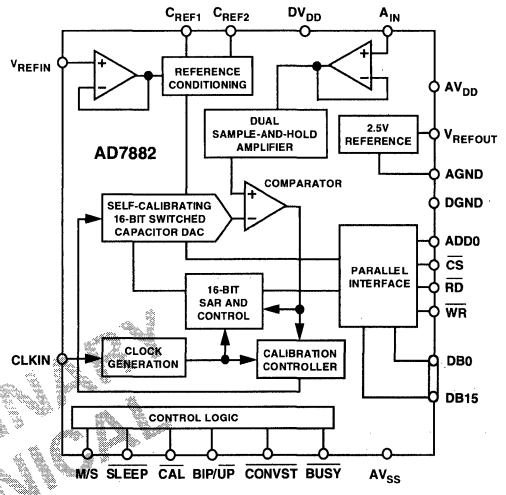
Pin No.	Pin Mnemonic	Function
1	V_{INA}	Analog Input.
2	V_{INB}	Analog Input.
3	AGND	Analog Ground.
4	V_{REF}	Voltage Reference Input. This is normally tied to V_{DD}.
5	$\overline{CS}$	Chip Select. Active Low Logic input. The device is selected when this input is active.
6	$\overline{CONVST}$	Convert Start. A low to high transition on this input puts the track/hold into hold mode and starts conversion. This input is asynchronous to the CLKIN and is independent of $\overline{CS}$ and $\overline{RD}$.
7	$\overline{RD}$	Read. Active Low Logic Input. This input is used in conjunction with $\overline{CS}$ low to enable data outputs.
8	$\overline{BUSY}$	Active Low Logic Output. This status line indicates converter status. $\overline{BUSY}$ is low during conversion.
9	CLKIN	Clock Input. TTL-compatible logic input. Used as the clock source for the A/D converter. The mark/space ratio of the clock can vary from 40/60 to 60/40.
10	DGND	Digital Ground.
11 . . . 22	DB0–DB11	Three-State Data Outputs. These become active when $\overline{CS}$ and $\overline{RD}$ are brought low.
23	MODE	MODE Input. This input is used to put the device into the power save mode (MODE = 0 V). During normal operation, the MODE input will be a logic high (MODE = V_{DD}).
24	V_{DD}	Power Supply. This is nominally +5 V.

LC²MOS
16-Bit, 2.5 µs, Sampling ADC
AD7882

FEATURES
- 2.5 µs Throughput Time
- 16-Bit Sampling ADC
- Self-Calibration
- High Speed Parallel Interface
- 92 dB Signal-to-Noise Ratio
- Low Power: 200 mW typ
  1 mW in Power-Down Mode
- Unipolar and Bipolar Input Signal Ranges
- On-Chip 2.5 V Reference
- Operates from ±5 V Supplies

APPLICATIONS
- Data Acquisition Systems
- Digital Signal Processing
- Spectrum Analysis
- DSP Servo Control

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7882 is a fast, 16-bit self-calibrating A/D converter. It consists of a sample-and-hold amplifier, a self-calibrating 16-bit ADC, a 2.5 V reference and versatile interface logic. An on-chip controller manages the self-calibrating algorithm that reduces linearity, offset and gain errors to ±0.0015%. System offset and gain errors, caused by external conditioning circuitry, can also be included in the calibration procedure. Throughput time is minimized at 2.5 µs by the use of a dual sample-and-hold amplifier. The ADC also has a self-contained internal clock which is laser trimmed to guarantee accurate control of conversion time; alternatively, an external clock may be used.

Another feature of the AD7882 is a power-down mode that reduces power dissipation from its normal operating value of 200 mW to 1 mW.

The AD7882 operates from ±5 V supplies. Analog input ranges can be unipolar, 0 to 2.5 V or bipolar, ±2.5 V. The analog input bandwidth is 200 kHz.

In addition to traditional dc accuracy specifications such as linearity, the AD7882 is also fully specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio (SNR).

The AD7882 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power high-speed CMOS logic. The part is available in a 44-pin plastic quad flatpack (PQFP) and 40-pin cerdip.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

PRODUCT HIGHLIGHTS

1. Fast 2.5 µs Throughput Time
   A fast 2.5 µs throughput time makes the AD7882 suitable for a wide range of data acquisition applications.
2. Self-Calibration Achieves High Accuracy
   A self-calibrating algorithm minimizes linearity, offset and gain errors. The calibration procedure can also include external offset and gain errors.
3. Dynamic Specifications for DSP Users
   In addition to traditional dc specifications, the AD7882 is specified for ac parameters including signal-to-noise ratio and harmonic distortion. These parameters along with important timing parameters are tested on every device.
4. Fast, Versatile Microprocessor Interface
   Fast bus access times and standard control signals make the AD7882 easy to interface to microprocessors.
5. Low Power
   Low power monolithic solution allows ease of application. The AD7882 also has a power down facility.

AD7882—SPECIFICATIONS (AV_{DD} = 5 V ± 5%, DV_{DD} = 5 V ± 5%, AV_{SS} = –5 V ± 5%, V_{REFIN} = 2.5 V, AGND = DGND = 0 V, f_{CLKIN} = 10 MHz, f_{SAMPLE} = 400 kHz. All specifications T_{MIN} to T_{MAX} unless otherwise noted.)

NOTES

[1]Timing Specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]t_{13} is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_{14} is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time, t_{14}, quoted in the Timing Specifications is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

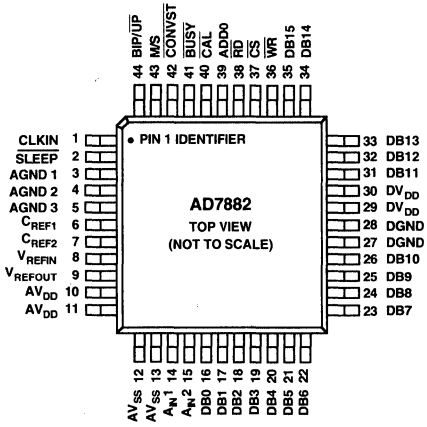
NOTES

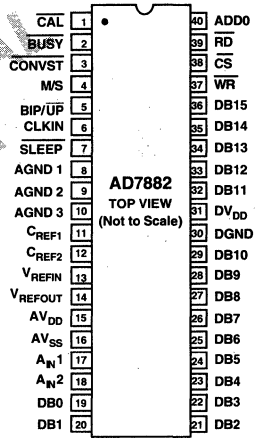
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]Transient currents of up to 100 mA will not cause SCR latch-up.

PQFP Pinout



Cerdip Pinout



CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7882 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN FUNCTION DESCRIPTION

Pin Mnemonic	Function
Power Supply	
DV_{DD}	Digital positive supply, +5 V ± 5%.
AV_{SS}	Analog negative supply, –5 V ± 5%.
AV_{DD}	Analog positive supply, +5 V ± 5%.
DGND	Digital Ground. Ground reference for digital circuitry.
AGND	Analog Ground. Ground reference for analog circuitry.
Analog and Reference Pins	
$A_{IN}1$, $A_{IN}2$	Analog Inputs. Both analog inputs must be tied together. The input ranges are; 0 V to 2.5 V and ±2.5 V.
V_{REFIN}	Voltage Reference Input. The AD7882 is specified with a voltage reference of 2.5 V, which can be provided externally or by the on-chip voltage reference.
V_{REFOUT}	Voltage Reference Output. The internal 2.5 V reference is provided at this pin. It has an output impedance which is nominally 20 kΩ.
C_{REF1}	10 µF Reference Capacitor. This is a charge reservoir for the coarse internal reference buffer, and it damps voltage excursions at the buffer output. This must be a high quality, low series inductance capacitor.
C_{REF2}	0.2 µF Reference Capacitor. This is a charge reservoir for the fine internal reference buffer, and it damps voltage excursions at the buffer output. This must be a high quality, low series inductance capacitor.
Interface	
$\overline{RD}$	Read, active low logic input. This input is used in conjunction with $\overline{CS}$ low to enable the three-state data outputs.
$\overline{CS}$	Chip select, active low logic input. The device is selected when this input is active.
ADD0	Address Input. This control input determines whether the word placed on the output data bus during a read operation is an ADC conversion result or the contents of the control register. A logic low accesses a conversion result while a logic high accesses the control register. When writing, if ADD0 is high, the control register is the destination. If ADD0 is low, the calibration data memory is the destination.
$\overline{WR}$	Write, active low logic input. This input is used in conjunction with $\overline{CS}$ and ADD0 to write data to the AD7882.
DB15–DB0	Three-state data outputs which are controlled by $\overline{CS}$ and $\overline{RD}$. Data output coding is 2s complement binary.
Timing and Control	
CLKIN	Clock input, an external TTL-compatible clock may be applied to this input pin. Alternatively, tying this pin to AV_{SS} enables the internal clock oscillator.
$\overline{BUSY}$	This output indicates converter status. $\overline{BUSY}$ is low during conversion and calibration.
$\overline{CONVST}$	Conversion Start. A low to high transition on this logic input pin, when the AD7882 is configured for asynchronous operation, places the sample-and-hold amplifier in the hold mode and starts conversion.
BIP/$\overline{UP}$	Bipolar/Unipolar select logic input. A logic high selects the bipolar input range (A_{IN} Range = $\pm V_{REFIN}$), and a logic low selects the unipolar range (A_{IN} Range = 0 to V_{REFIN}).
$\overline{SLEEP}$	Sleep function, active low logic input. Once asserted, the AD7882 enters the low power mode. All internal circuitry including the internal voltage reference is powered down. Calibration data is retained.
$\overline{CAL}$	Active low logic input. A logic low on this input resets all internal logic and initiates a calibration. Initiating a calibration overrides all other internal operations and if a conversion is in progress, it will be terminated.
M/S	Mode/Sync Logic Input. This is a dual function pin. When the device is in the CAL mode ($\overline{CAL}$ input low), it determines the calibration mode. When the device is in the normal operating mode, it determines whether conversion is synchronous or asynchronous. Synchronous operation means that the device continuously converts the input in synchronism with the clock. Asynchronous operation means that the device converts the analog input in response to the application of a $\overline{CONVST}$ signal. See Table I for the $\overline{CAL}$, M/S Truth Table. Note that the control register can be used to disable this input pin. See Control Register Section.

Table I. AD7882 Operating Modes

$\overline{CAL}$	M/S	Function
1	0	Asynchronous Operation
1	1	Synchronous Operation
0	0	Device Calibration
0	1	System Calibration

TERMINOLOGY

Integral Nonlinearity
This is the maximum deviation of any code from a straight line passing through the endpoints of the ADC transfer function. The endpoints of the transfer function are zero scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed in LSBs.

Differential Nonlinearity/No Missed Codes
This is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC. Differential linearity error is expressed in LSBs. A differential linearity error of ±0.9 LSB or less guarantees no missed codes to the full resolution of the device. Thus, the AD7882 has no missed codes guaranteed to 16 bits.

Unipolar Offset Error
When the device is operating in the 0 to $+V_{REFIN}$ range, the deviation of the first code transition from the ideal (+0.5 LSB) is the unipolar offset error. It is expressed in LSBs.

Unipolar Gain Error
This is the deviation of the last code transition (01 . . . 110 to 01 . . . 111) from the ideal (V_{REFIN} – 1.5 LSB) after bipolar zero error has been adjusted out.

Bipolar Zero Error
This is the deviation of the midscale transition (all 0s to all 1s) from the ideal (AGND).

Positive Gain Error
This is the deviation of the last code transition (01 . . . 110 to 01 . . . 111) from the ideal (V_{REFIN} – 1.5 LSB) after bipolar zero error has been adjusted out.

Negative Gain Error
This is the deviation of the first code transition (10 . . . 000 to 10 . . . 001) from the ideal ($-V_{REFIN}$ + 0.5 LSB) after bipolar zero error has been adjusted out.

Signal to (Noise + Distortion) Ratio
This is the measured ratio of signal to (noise + distortion) at the output of the A/D converter. The signal is the rms amplitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio is dependent upon the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to (noise +distortion) ratio for an ideal N-bit converter with a sine wave input is given by:

$$\textit{Signal to (Noise + Distortion)} = (6.02N + 1.76)\ \text{dB}$$

Thus for a 16-bit converter, this is 98 dB.

Total Harmonic Distortion
Total harmonic distortion (THD) is the ratio of the rms sum of harmonics to the fundamental. For the AD7882, it is defined as

$$THD\ (dB) = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonics.

Peak Harmonic or Spurious Noise
Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor, it will be a noise peak.

Intermodulation Distortion
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither m nor n are equal to zero. For example, the second order terms include (fa + fb) and (fa – fb), while the third order terms include (2fa + fb), (2fa – fb), (fa + 2fb) and (fa – 2fb).

The AD7882 is tested using the CCIF standard where two input frequencies near the top end of the input bandwidth are used. In this case, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves, while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

Power Supply Rejection Ratio
This is the ratio, in dBs, of the change in positive gain error to the change in AV_{DD}, DV_{DD} or AV_{SS}. It is a dc measurement.

CIRCUIT DESCRIPTION

Analog Input

The analog input circuitry includes two SHAs in a ping-pong configuration as in Figure 8. The SHAs alternatively acquire the analog input and hold the output constant for the ADC conversions. During conversion, one of the SHAs is in the hold mode while the other is in the sample mode. The sample and

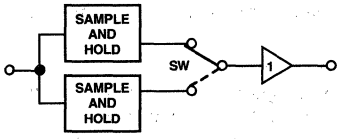


Figure 8. Input SHA Configuration

hold states are then switched after every conversion. The benefit of this configuration is to eliminate the need for acquisition time between conversions. The throughput time is now effectively equal to the conversion time which is 2.5 µs. The analog input range can be either unipolar or bipolar depending on the status of the BIP/$\overline{UP}$ input. The transfer function for the unipolar range is straight binary while the transfer function for the bipolar input is 2s complement. These are shown in Figures 9 and 10.

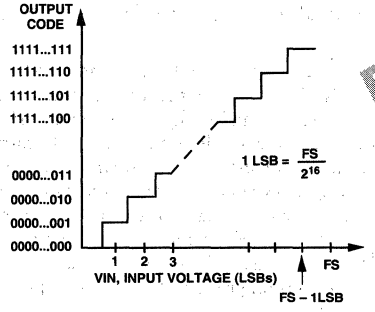

Figure 9. Unipolar Transfer Function

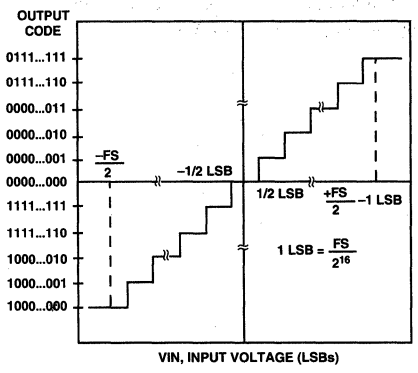

Figure 10. Bipolar Transfer Function

Calibration

The AD7882 conversion procedure is based on the successive approximation algorithm. Accuracy of the individual components, such as the DAC and comparator, is critical to achieve 16-bit performance. The comparator uses an autozero technique to null both internal and external offsets. Another advantage of this scheme is that it nulls 1/f noise. The autozero switching occurs well above the 1/f roll-off frequency, thus the noise appears as a dc offset which gets cancelled.

The internal DAC uses binary weighted capacitors instead of the traditional R-2 R ladder type. This allows the AD7882 to employ a calibration routine that nulls the errors of the individual DAC segments along with offset and gain errors. Each segment of the capacitor DAC contains multiple capacitors that are used to trim for absolute accuracy. During a calibration routine, the DAC segments are compared against other segments and trimmed to 1/4 LSB accuracy. Offset and gain errors are then calibrated either against the device AGND and V_{REFIN} inputs or external reference voltages that are applied at the A_{IN} input.

Calibration Routine

The AD7882 is capable of two calibration methods; system calibration and device calibration. Both modes calibrate the internal DAC linearity along with offset and gain errors. A system calibration is where the device calibrates its full scale and offset voltages against externally applied voltages. For a device calibration, full scale and offset are calibrated against the V_{REFIN} and AGND inputs. Note that a calibration must always be initiated after power on to meet the device performance specifications.

Calibration may be initiated in hardware by asserting the $\overline{CAL}$ pin or in software by writing the appropriate word to the control register. The AD7882 will always perform a full calibration if initiated in hardware. However, under software control, partial calibration options including only offset and gain, can be performed. These options are shown in Table III.

Device Calibration

Device calibration is initiated by pulsing $\overline{CAL}$ low; see Figure 6. Offset and gain are calibrated against the AGND and V_{REFIN} inputs respectively. This calibration procedure takes 928 ms, when using a 10 MHz clock.

System Calibration

System calibration is initiated by a positive edge on $\overline{CAL}$ as shown in Figure 7. $\overline{BUSY}$ goes low three times during the calibration procedure corresponding to the DAC, offset and gain calibrations respectively. The rising edge of the first $\overline{BUSY}$ pulse indicates that the DAC calibration is complete and the AD7882 is now ready to calibrate the offset. This is achieved by applying an external 0 V input at the A_{IN} input and asserting the $\overline{CONVST}$ input. Note, the external 0 V input must be within ±1.5% of AGND. The rising edge of the second $\overline{BUSY}$ pulse indicates that the part is ready to calibrate full scale. This time, the full scale input voltage must be applied to the analog input, and $\overline{CONVST}$ must be asserted once again. The full-scale input voltage must be within ±1.5% of the reference input voltage. Complete calibration time is 928 ms plus the width of the two $\overline{CONVST}$ start pulses, when using a 10 MHz clock for the device.

Configuring the M/S Input

The M/S input with conjunction with the $\overline{CAL}$ input determines the type of calibration initiated when $\overline{CAL}$ is taken low. It also determines whether the conversion is asynchronous (controlled by the $\overline{CONVST}$ input) or synchronous (with CLKIN). In all, they can be configured in four different ways as shown in Figure 11. The $\overline{CAL}$ input is asserted by a positive edge, when calibration is required. Then, for example if synchronous operation and device calibration is required, M/S is tied to $\overline{CAL}$. Note, an inverter can be used between the $\overline{CAL}$ and the M/S inputs when asynchronous operation and system calibration is required.

If $\overline{CAL}$ is high, then the user can start a Calibration from the Control Register.

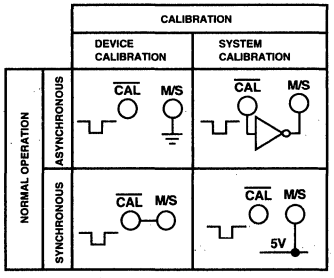

Figure 11. M/S Input Configuration

Timing and Control

Data communication with the AD7882 is controlled by four control inputs: $\overline{CS}$, $\overline{RD}$, $\overline{WR}$ and ADD0. The data transfer consists of reading and writing to the control register or coefficients register and reading the conversion result from the output data register.

Conversion Control and Data Reads

Conversion can be controlled in hardware by asserting the $\overline{CONVST}$ input (Asynchronous Mode) or the device can be set up for continuous "back-to-back" conversions (Synchronous Mode). The M/S input controls these as outlined above. In synchronous mode, a power-up, CAL or CONVST will initiate operation.

The data outputs are controlled by the $\overline{CS}$ and $\overline{RD}$ inputs. The possible timing configurations are shown in Figures 3, 4 and 5. If $\overline{CS}$ and $\overline{RD}$ are tied permanently low, then the data bus will always be active. However, it will change state at the end of conversion to reflect the most recent result. Reading the data bus must be avoided at this time.

Control Register

The control register serves the dual function of providing control and monitoring the status of the AD7882. This register is directly accessible through the data bus with a read or write operation while ADD0 is high. One of the option settings in the control register is to set up the coefficients register for reading or writing. The coefficient registers contain the calibration coefficients. Loading the coefficients to the register consists of writing forty 16-bit words. This activity is considerably shorter for almost any processor than performing a calibration. Thus, a typical application might read all the coefficients after calibration, store them in the backup memory and rewrite them to the AD7882 in future power-up initialization routines. Reading the calibration coefficients consists of forty read cycles to the AD7882. This will return forty 16-bit words to the microprocessor.

Writing to the AD7882

Data can be written to either the control register or the coefficients register. A typical timing diagram is shown in Figure 12.

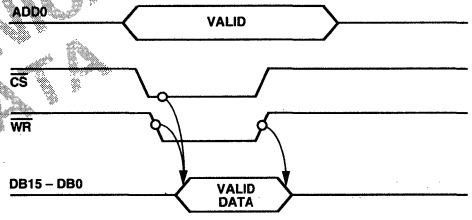

Figure 12. Typical Write Timing

Table II. Control Register Bit Functions

Bit Location	I/O Option	Power-Up Default	Function
CR0	Read Only	0	Conversion status. This bit is high during conversion.
CR1	Read Only	0	Calibration status. This bit is high during calibration.
CR2	Read/Write	BIP/$\overline{UP}$	BIP/$\overline{UP}$ Select. Unipolar operation is selected when CR2 is 0; bipolar operation is selected when CR2 is 1. This assumes that CR3 is 1. When CR3 is 0, CR2 reflects the BIP/$\overline{UP}$ input.
CR3	Read/Write	0	If CR3 = 1, then Control Register bits CR2, CR9 and CR10 have priority. Otherwise external pins, $\overline{SLEEP}$ and BIP/$\overline{UP}$, have priority.
CR4	Read/Write	0	CR4 to CR7 determine the calibration function, see Table III.
CR5	Read/Write	1	Calibration function, See CR4.
CR6	Read/Write	1	Calibration function, See CR4.
CR7	Read/Write	1	Calibration function, See CR4.
CR8			Not Used
CR9	Read/Write	$\overline{SLEEP}$	Sleep Control Bit. When CR3 is 1, setting CR9 to 0 powers down all circuitry except the reference. When CR3 is 0, CR9 reflects the state of the $\overline{SLEEP}$ input.
CR10	Read/Write	$\overline{SLEEP}$	Reference power down. When CR3 is 1, reference is powered by writing a 0 to CR10. When CR3 is 0, CR10 reflects the state of the $\overline{SLEEP}$ input.
CR11	Read	0	A 1 in this location indicates an overflow on A_{IN} in the last conversion and a gain adjust is required to bring the input back within range.
CR12	Read	0	A 1 in this location indicates an underflow on A_{IN} in the last conversion and a gain adjust is required to bring the input back within range.
CR13			Not Used
CR14	Read/Write	0	Status Bit. If this is 1, it means that the calibration is halted. Calibration can be continued by writing a 0 to this location.
CR15	Read/Write	1	Reset Bit. All memory and logic is reset when a 0 is written to this location. Reset happens on the rising edge of $\overline{WR}$. If there is a subsequent control register read all bits except CR15 will have power-up default setting. Therefore, to restart after a software reset, it is necessary to write a 1 back into CR15.

Table III. Calibration Options Using the Control Register

CR7	CR6	CR5	CR4	Function
0	0	0	0	Normal Conversion, No Calibration
0	0	0	1	Normal Conversion, No Calibration
0	0	1	0	Gain Error Only–Device Calibration
0	0	1	1	Gain Error Only–System Calibration
0	1	0	0	Offset Error Only–Device Calibration
0	1	0	1	Offset Error Only–System Calibration
0	1	1	0	Offset and Gain Error Only–Device Calibration
0	1	1	1	Offset and Gain Error Only–System Calibration
1	0	0	0	Read All Calibration Coefficients
1	0	0	1	Write All Calibration Coefficients
1	0	1	0	Read Gain Calibration Coefficients Only
1	0	1	1	Write Gain Calibration Coefficients Only
1	1	0	0	Read Offset Calibration Coefficients Only
1	1	0	1	Write Offset Calibration Coefficients Only

LC²MOS 12-Bit, 3.3 V Sampling ADC

AD7883

FEATURES

Battery-Compatible Supply Voltage: Guaranteed Specs for V_{DD} of 3 V to 3.6 V
12-Bit Monolithic A/D Converter
50 kHz Throughput Rate
15 μs Conversion Time
5 μs On-Chip Track/Hold Amplifier
Low Power
Power Save Mode: 1 mW typ
Normal Operation: 8 mW typ
70 dB SNR
Small 24-Lead SOIC and 0.3" DIP Packages

APPLICATIONS

Battery Powered Portable Systems
Laptop Computers

GENERAL DESCRIPTION

The AD7883 is a high speed, low power, 12-bit A/D converter which operates from a single +3 V to +3.6 V supply. It consists of a 5 μs track/hold amplifier, a 15 μs successive-approximation ADC, versatile interface logic and a multiple-input-range circuit. The part also includes a power save feature.

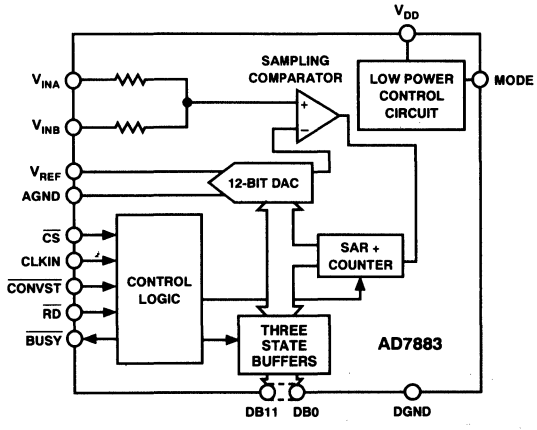
Fast bus access times and standard control inputs ensure easy interfacing to modern microprocessors and digital signal processors.

The AD7883 features a total throughput time of 20 μs and can convert full power signals up to 25 kHz with a sampling frequency of 50 kHz.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7883 is also fully specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The AD7883 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin, 0.3 inch-wide, plastic dual-in-line package (DIP) as well as a small 24-lead SOIC package.

FUNCTIONAL BLOCK DIAGRAM



PRODUCT HIGHLIGHTS

1. 3 V Operation
   The AD7883 is guaranteed and tested with a supply voltage of 3 V to 3.6 V. This makes it ideal for battery-powered applications where 12-bit A/D conversion is required.
2. Fast Conversion Time
   15 μs conversion time and 5 μs acquisition time allow for large input signal bandwidth. This performance is ideally suited for applications in areas such as telecommunications, audio, sonar and radar signal processing.
3. Low Power Consumption
   1 mW power consumption in the power-down mode makes the part ideally suited for portable, hand held, battery powered applications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7883—SPECIFICATIONS (V_{DD} = +3 V to +3.6 V, V_{REF} = V_{DD}, AGND = DGND = 0 V, f_{CLKIN} = 2 MHz, MODE = Logic High. All specifications T_{MIN} to T_{MAX} unless otherwise noted.)

Parameter	B Versions[1]	Units	Test Conditions/Comments
DYNAMIC PERFORMANCE[2]			
Signal-to-Noise Ratio[3] (SNR)	69	dB min	Typically SNR Is 71 dB V_{IN} = 1 kHz Sine Wave, f_{SAMPLE} = 50 kHz

t_5	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time
t_6	**110**	**150**	ns min	$\overline{RD}$ Pulse Width
t_7[2]	**100**	**140**	ns max	Data Access Time after $\overline{RD}$
t_8[3]	**5**	**5**	ns min	Bus Relinquish Time after $\overline{RD}$
	90	**90**	ns max	

NOTES

[1]Timing specifications in **bold** print are 100% production tested. All other times are sample tested at 25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]t_7 is measured with the load circuit of Figure 2 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[3]t_8 is derived from the measured time taken by the data outputs to change by 0.5 V when loaded with the circuit of Figure 2. The measured number is then extrapolated back to remove the effects of charging the 50 pF capacitor. This means that the time, t_8, quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

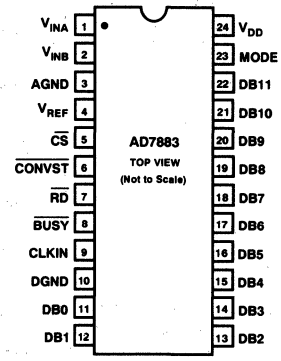
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

PIN CONFIGURATION



CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

Pin No.	Pin Mnemonic	Function
1	V_{INA}	Analog Input.
2	V_{INB}	Analog Input.
3	AGND	Analog Ground.
4	V_{REF}	Voltage Reference Input. This is normally tied to V_{DD}.
5	$\overline{CS}$	Chip Select. Active Low Logic input. The device is selected when this input is active.
6	$\overline{CONVST}$	Convert Start. A low to high transition on this input puts the track/hold into hold mode and starts conversion. This input is asynchronous to the CLKIN and is independent of $\overline{CS}$ and $\overline{RD}$.
7	$\overline{RD}$	Read. Active Low Logic Input. This input is used in conjunction with $\overline{CS}$ low to enable data outputs.
8	$\overline{BUSY}$	Active Low Logic Output. This status line indicates converter status. $\overline{BUSY}$ is low during conversion.
9	CLKIN	Clock Input. TTL-compatible logic input. Used as the clock source for the A/D converter. The mark/space ratio of the clock can vary from 40/60 to 60/40.
10	DGND	Digital Ground.
11 . . . 22	DB0–DB11	Three-State Data Outputs. These become active when $\overline{CS}$ and $\overline{RD}$ are brought low.
23	MODE	MODE Input. This input is used to put the device into the power save mode (MODE = 0 V). During normal operation, the MODE input will be a logic high (MODE = V_{DD}).
24	V_{DD}	Power Supply. This is nominally +3.3 V.

Robotics

GENERAL DESCRIPTION

The AD7884/AD7885 is a 16-bit monolithic analog-to-digital converter with internal sample-and-hold and a conversion time of 5.3 μs. The maximum throughput rate is 166 kSPS. It uses a two pass flash architecture to achieve this speed. Two input ranges are available: ±5 V and ±3 V. Conversion is initiated by the $\overline{\text{CONVST}}$ signal. The result can be read into a microprocessor using the $\overline{\text{CS}}$ and $\overline{\text{RD}}$ inputs on the device. The AD7884 has a 16-bit parallel reading structure while the AD7885 has a byte reading structure. The conversion result is in 2s complement code.

The AD7884/AD7885 has its own internal oscillator which controls conversion. It runs from ±5 V supplies and needs a V_{REF+} of +3 V.

The AD7884 is available in a 40-pin plastic DIP package and in a 44-pin PLCC package.

The AD7885 is available in a 28-pin plastic DIP package and the AD7885A is available in a 44-pin PLCC package.

FUNCTIONAL BLOCK DIAGRAMS

NOTES

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

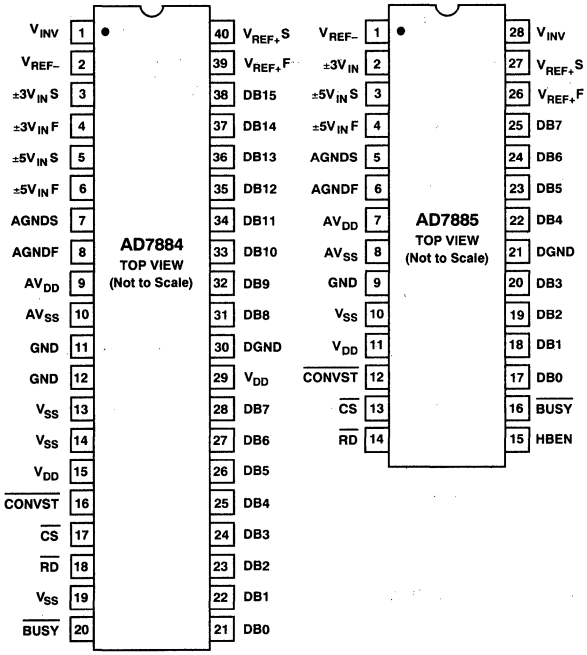
[2]If the AD7884/AD7885 is being powered from separate analog and digital supplies, AV_{SS} should always come up before V_{SS}. See Figure 13 for a recommended protection circuit using Schottky diodes.

CAUTION

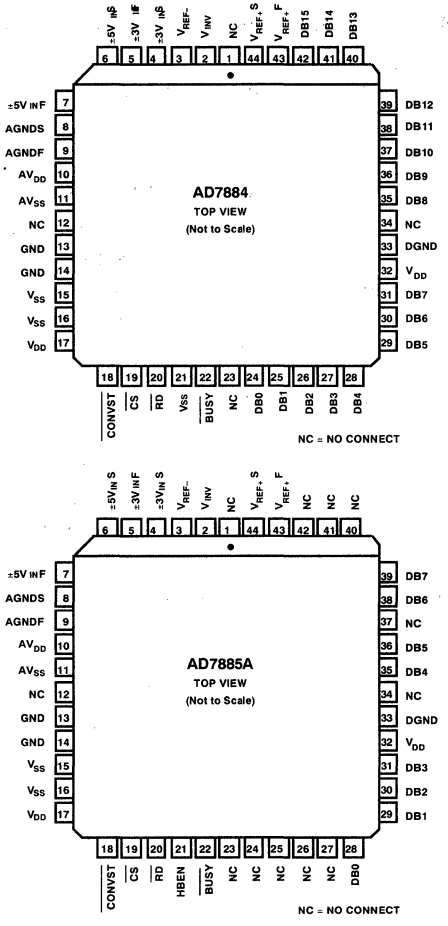
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN CONFIGURATIONS

DIP



PLCC



PIN FUNCTION DESCRIPTION

AD7884	AD7885	AD7885A	Description
V_{INV}	V_{INV}	V_{INV}	This pin is connected to the inverting terminal of an op amp, as in Figure 6, and allows the inversion of the supplied +3 V reference.
V_{REF-}	V_{REF-}	V_{REF-}	This is the negative reference input, and it can be obtained by using an external amplifier to invert the positive reference input. In this case, the amplifier output is connected to V_{REF-}. See Figure 6.
$\pm 3V_{IN}S$	—	$\pm 3V_{IN}S$	This is the analog input sense pin for the ±3 volt analog input range on the AD7884 and AD7885A.
$\pm 3V_{IN}F$	—	$\pm 3V_{IN}F$	This is the analog input force pin for the ±3 volt analog input range on the AD7884 and AD7885A. When using this input range, the ±5 $V_{IN}F$ and ±5 $V_{IN}S$ pins should be tied to AGND.
—	$\pm 3V_{IN}$	—	This is the analog input pin for the ±3 volt analog input range on the AD7885. When using this input range, the ±5 $V_{IN}F$ and ±5 $V_{IN}S$ pins should be tied to AGND.
$\pm 5V_{IN}S$	$\pm 5V_{IN}S$	$\pm 5V_{IN}S$	This is the analog input sense pin for the ±5 volt analog input range on both the AD7884, AD7885 and AD7885A.
$\pm 5V_{IN}F$	$\pm 5V_{IN}F$	$\pm 5V_{IN}F$	This is the analog input force pin for the ±5 volt analog input range on both the AD7884, AD7885 and AD7885A. When using this input range, the ±3 $V_{IN}F$ and ±3 $V_{IN}S$ pins should be tied to AGND.
AGNDS	AGNDS	AGNDS	This is the ground return sense pin for the 9-bit ADC and the on-chip residue amplifier.
AGNDF	AGNDF	AGNDF	This is the ground return force pin for the 9-bit ADC and the on-chip residue amplifier.
AV_{DD}	AV_{DD}	AV_{DD}	Positive analog power rail for the sample-and-hold amplifier and the residue amplifier.
AV_{SS}	AV_{SS}	AV_{SS}	Negative analog power rail for the sample-and-hold amplifier and the residue amplifier.
GND	GND	GND	This is the ground return for sample-and-hold section.
V_{SS}	V_{SS}	V_{SS}	Negative supply for the 9-bit ADC.
V_{DD}	V_{DD}	V_{DD}	Positive supply for the 9-bit ADC and all device logic.
$\overline{CONVST}$	$\overline{CONVST}$	$\overline{CONVST}$	This asynchronous control input starts conversion.
$\overline{CS}$	$\overline{CS}$	$\overline{CS}$	Chip Select control input.
$\overline{RD}$	$\overline{RD}$	$\overline{RD}$	Read control input. This is used in conjunction with $\overline{CS}$ to read the conversion result from the device output latch.
—	HBEN	HBEN	High Byte Enable. Active high control input for the AD7885. It selects either the high or the low byte of the conversion for reading.
$\overline{BUSY}$	$\overline{BUSY}$	$\overline{BUSY}$	Busy output. The Busy output goes low when conversion begins and stays low until it is completed, at which time it goes high.
DB0–DB15	—	—	Sixteen-bit parallel data word output on the AD7884.
—	DB0–DB7	DB0–DB7	Eight-bit parallel data byte output on the AD7885.
DGND	DGND	DGND	Ground return for all device logic.
$V_{REF+}F$	$V_{REF+}F$	$V_{REF+}F$	Reference force input.
$V_{REF+}S$	$V_{REF+}S$	$V_{REF+}S$	Reference sense input. The device operates from a +3 V reference.

TERMINOLOGY

Integral Nonlinearity
This is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function.

Differential Nonlinearity
This is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Bipolar Zero Error
This is the deviation of the midscale transition (all 0s to all 1s) from the ideal (AGND).

Positive Gain Error
This is the deviation of the last code transition (01 . . . 110 to 01 . . . 111) from the ideal ($+V_{REF+}$ S − 1 LSB), after Bipolar Zero Error has been adjusted out.

Negative Gain Error
This is the deviation of the first code transition (10 . . . 000 to 10 . . . 001) from the ideal ($-V_{REF+}$S + 1 LSB), after Bipolar Zero Error has been adjusted out.

Signal to (Noise + Distortion) Ratio
This is the measured ratio of signal to (noise + distortion) at the output of the A/D converter. The signal is the rms amplitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio is dependent upon the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to (noise + distortion) ratio for an ideal N-bit converter with a sine wave input is given by:

$$\textit{Signal to (Noise + Distortion)} = (6.02N + 1.76)\ dB$$

Thus for an ideal 16-bit converter, this is 98 dB.

Total Harmonic Distortion
Total harmonic distortion (THD) is the ratio of the rms sum of harmonics to the fundamental. For the AD7884/AD7885, it is defined as:

$$THD\ (dB) = 20\ log\ \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonics.

Peak Harmonic or Spurious Noise
Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor, it will be a noise peak.

Intermodulation Distortion
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa + fb) and (fa − fb), while the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb).

The AD7884/AD7885 is tested using the CCIFF standard where two input frequencies near the top end of the input bandwidth are used. In this case, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

Power Supply Rejection Ratio
This is the ratio, in dBs, of the change in positive gain error to the change in V_{DD} or V_{SS}. It is a dc measurement.

OPERATIONAL DIAGRAM

An operational diagram for the AD7884/AD7885 is shown in Figure 6. It is set up for an analog input range of ±5 V. If a ±3 V input range is required, A1 should drive ±3 V_{IN}S and ±3 V_{IN}F with ±5 V_{IN}S, ±5 V_{IN}F being tied to system AGND.

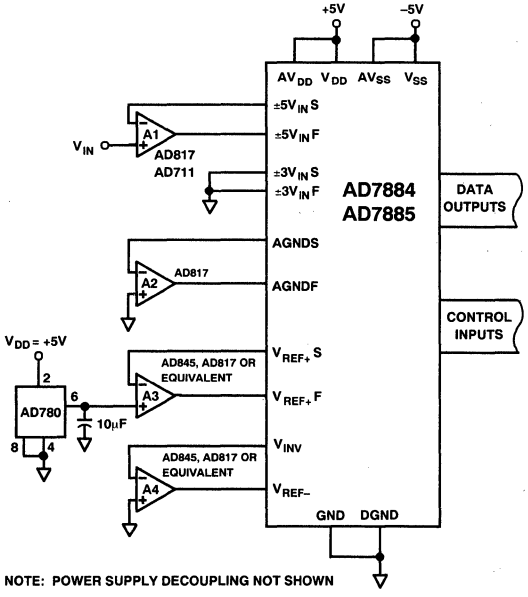


Figure 6. AD7884/AD7885 Operational Diagram

The chosen input buffer amplifier (A1) should have low noise and distortion and fast settling time for high bandwidth applications. Both the AD711 and the AD845 are suitable amplifiers.

A2 is the force, sense amplifier for AGND. The AGNDS pin should be at zero potential. Therefore, the amplifier must have a low input offset voltage and good noise performance. It must also have the ability to deal with fast current transients on the AGNDS pin. The AD817 has the required performance and is the recommended amplifier.

If AGNDS and AGNDF are simply tied together to Star Ground instead of buffering, the SNR and THD are not significantly degraded. However, dc specifications like INL, Bipolar Zero and Gain Error will be degraded.

The required +3 V reference is derived from the AD780 and buffered by the high-speed amplifier A3 (AD845, AD817 or equivalent). A4 is a unity gain inverter which provides the −3 V negative reference. The gain setting resistors are on-chip and are factory trimmed to ensure precise tracking of V_{REF+}. Figure 6 shows A3 and A4 as AD845s or AD817s. These have the ability to respond to the rapidly changing reference input impedance.

CIRCUIT DESCRIPTION

Analog Input Section

The analog input section of the AD7884/AD7885 is shown in Figure 7. It contains both the input signal conditioning and sample-and-hold amplifier. Note that the analog input is truly benign. When SW1a goes open circuit to put the SHA into the hold mode, SW1b is closed. This means that the input resistors, R1 and R2 are always connected to either virtual ground or true ground.

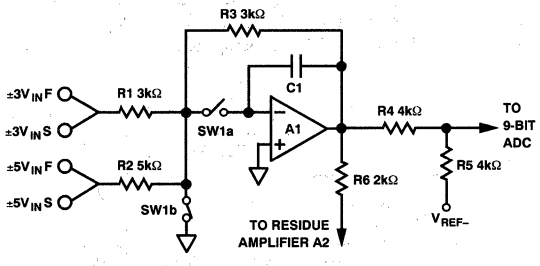

Figure 7. AD7884/AD7885 Analog Input Section

When the ±3 V_{IN}S and ±3 V_{IN}F inputs are tied to 0 V, the input section has a gain of −0.6 and transforms an input signal of ±5 volts to the required ±3 volts. When the ±5 V_{IN}S and ±5 V_{IN}F inputs are grounded, the input section has a gain of −1 and so the analog input range is now ±3 volts. Resistors R4 and R5, at the amplifier output, further condition the ±3 volts signal to be 0 to −3 volts. This is the required input for the 9-bit A/D converter section.

With SW1a closed, the output of A1 follows the input (the sample-and-hold is in the track mode). On the rising edge of the $\overline{\text{CONVST}}$ pulse, SW1a goes open circuit, and capacitor C1 holds the voltage on the output of A1. The sample-and-hold is now in the hold mode. The aperture delay time for the sample-and-hold is nominally 50 ns.

A/D Converter Section

The AD7884/AD7885 uses a two-pass flash technique in order to achieve the required speed and resolution. When the $\overline{\text{CONVST}}$ control input goes from low to high, the sample-and-hold amplifier goes into the hold mode and a 0 V to −3 V signal is presented to the input of the 9-bit ADC. The first phase of conversion generates the 9 MSBs of the 16-bit result and transfers these to the latch and ALU combination. They are also fed back to the 9 MSBs of the 16-bit DAC. The 7 LSBs of the DAC are permanently loaded with 0s. The DAC output is subtracted from the analog input with the result being amplified and offset in the Residue Amplifier Section. The signal at the output of A2 is proportional to the error between the first phase result and the actual analog input signal and is digitized in the second conversion phase. This second phase begins when the 16-bit DAC and the Residue Error Amplifier have both settled. First, SW2 is turned off and SW3 is turned on. Then, the SHA section of the Residue Amplifier goes into hold mode. Next SW2 is turned off and SW3 is turned on. The 9-bit result is transferred to the output latch and ALU. An error correction algorithm now compensates for the offset inserted in the Residue Amplifier Section and errors introduced in the first pass conversion and combines both results to give the 16-bit answer.

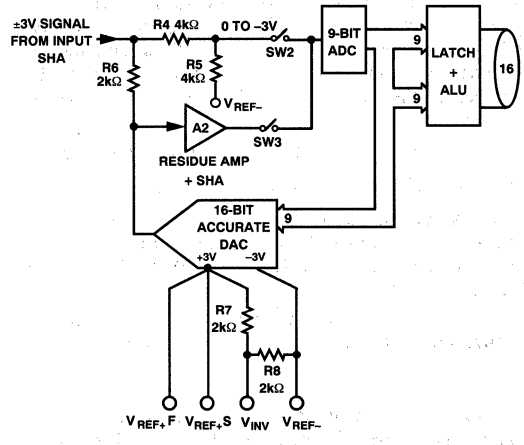

Figure 8. A/D Converter Section

Timing and Control Section

Figure 9 shows the timing and control sequence for the AD7884/AD7885. When the part receives a $\overline{\text{CONVST}}$ pulse, the conversion begins. The input sample-and-hold goes into the hold mode 50 ns after the rising edge of $\overline{\text{CONVST}}$ and $\overline{\text{BUSY}}$ goes low. This is the first phase of conversion and takes 3.35 μs to complete. The second phase of conversion begins when SW2 is turned off and SW3 turned on. The Residue Amplifier and SHA section (A2 in Figure 8) goes into hold mode at this point and allows the input sample-and-hold to go back into sample mode. Thus, while the second phase of conversion is ongoing, the input sample-and-hold is also acquiring the input signal for the next conversion. This overlap between conversion and acquisition allows throughput rates of 166 kSPS to be achieved.

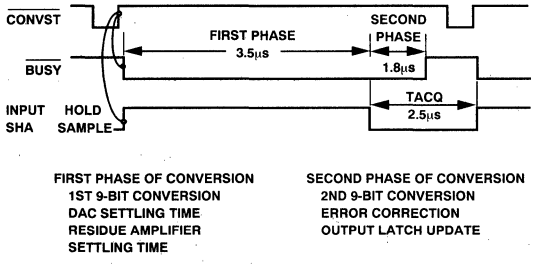

Figure 9. Timing and Control Sequence

USING THE AD7884/AD7885

Analog Input Ranges

The AD7884/AD7885 can be set up to have either a ±3 volts analog input range or a ±5 volts analog input range. Figures 10 and 11 show the necessary corrections for each of these. The output code is 2s complement and the ideal code table for both input ranges is shown in Table I.

Reference Considerations

The AD7884/AD7885 operates from a ±3 volt reference. This can be derived simply using the AD780 as shown in Figure 6.

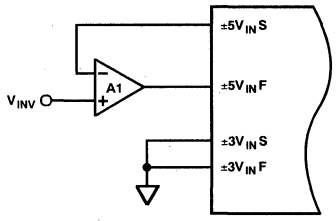

Figure 10. ±5 V Input Range Connection

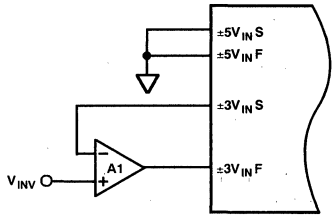

Figure 11. ±3 V Input Range Connections

The critical performance specification for a reference in a 16-bit application is noise. The reference pk-pk noise should be insignificant in comparison to the ADC noise. The AD7884/AD7885 has a typical rms noise of 120 μV. For example a reasonable target would be to keep the total rms noise less than 125 μV. To do this the reference noise needs to be less than 35 μV rms. In the 100 kHz band, the AD780 noise is less than 30 μV rms, making it a very suitable reference.

The buffer amplifier used to drive the device V_{REF+} should have low enough noise performance so as not to affect the overall system noise requirement. The AD845 and AD817 achieve this.

Table I. Ideal Output Code Table for the AD7884/AD7885

Analog Input			Digital Output
In Terms of FSR[2]	±3 V Range[3]	±5 V Range[4]	Code Transition[1]
+FSR/2 − 1 LSB	2.999908	4.999847	011 . . . 111 to 011 . . . 110
+FSR/2 − 2 LSBs	2.999817	4.999695	011 . . . 110 to 011 . . . 101
+FSR/2 − 3 LSBs	2.999726	4.999543	011 . . . 101 to 011 . . . 100
AGND + 1 LSB	0.000092	0.000153	000 . . . 001 to 000 . . . 000
AGND	0.000000	0.000000	000 . . . 000 to 111 . . . 111
AGND − 1 LSB	−0.000092	−0.000153	111 . . . 111 to 111 . . . 110
−(FSR/2 − 3 LSBs)	−2.999726	−4.999543	100 . . . 011 to 100 . . . 010
−(FSR/2 − 2 LSBs)	−2.999817	−4.999695	100 . . . 010 to 100 . . . 001
−(FSR/2 − 1 LSB)	−2.999908	−4.999847	100 . . . 001 to 100 . . . 000

NOTES
[1]This table applies for $V_{REF+}S$ = +3 V.
[2]FSR (Full-Scale Range) is 6 volts for the ±3 V input range and 10 volts for the ±5 V input range.
[3]1 LSB on the ±3 V range is FSR/2^{16} and is equal to 91.5 μV.
[4]1 LSB on the ±5 V range is FSR/2^{16} and is equal to 152.6 μV.

Decoupling and Grounding

The AD7884 and AD7885A have one AV_{DD} pin and two V_{DD} pins. They also have one AV_{SS} pin and three V_{SS} pins. The AD7885 has one AV_{DD} pin, one V_{DD} pin, one AV_{SS} pin and one V_{SS} pin. Figure 6 shows how a common +5 V supply should be used for the positive supply pins and a common −5 V supply for the negative supply pins.

For decoupling purposes, the critical pins on both devices are the AV_{DD} and AV_{SS} pins. Each of these should be decoupled to system AGND with 10 μF tantalum and 0.1 μF ceramic capacitors right at the pins. With the V_{DD} and V_{SS} pins, it is sufficient to decouple each of these with ceramic 1 μF capacitors.

AGNDS, AGNDF are the ground return points for the on-chip 9-bit ADC. They should be driven by a buffer amplifier as shown in Figure 6. If they are tied directly together and then to ground, there will be a marginal degradation in linearity performance.

The GND pin is the analog ground return for the on-chip linear circuitry. It should be connected to system analog ground.

The DGND pin is the ground return for the on-chip digital circuitry. It should be connected to the ground terminal of the V_{DD} and V_{SS} supplies. If a common analog supply is used for AV_{DD} and V_{DD} then DGND should be connected to the common ground point.

Power Supply Sequencing

AV_{DD} and V_{DD} are connected to a common substrate and there is typically 17 Ω resistance between them. If they are powered by separate +5 V supplies, then these should come up simultaneously. Otherwise, the one that comes up first will have to drive +5 V into a 17 Ω load for a short period of time. However, the standard short-circuit protection on regulators like the 7800 series will ensure that there is no possibility of damage to the driving device.

AV_{SS} should always come up either before or at the same time as V_{SS}. If this cannot be guaranteed, Schottky diodes should be used to ensure that V_{SS} never exceeds AV_{SS} by more than 0.3 V. Arranging the power supplies as in Figure 6 and using the recommended decoupling ensures that there are no power supply sequencing issues as well as giving the specified noise performance.

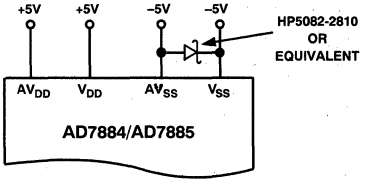

Figure 12. Schottky Diodes Used to Protect Against Incorrect Power Supply Sequencing

AD7884/AD7885 PERFORMANCE

Linearity

The linearity of the AD7884/AD7885 is determined by the on-chip 16-bit D/A converter. This is a segmented DAC which is laser trimmed for 16-bit DNL performance to ensure that there are no missing codes in the ADC transfer function. Figure 13 shows a typical INL plot for the AD7884/AD7885.

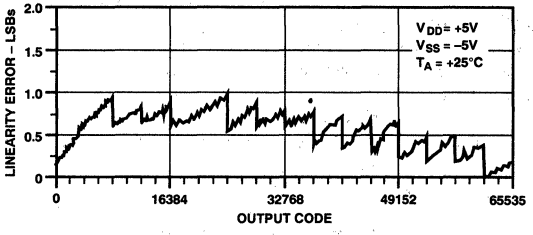

Figure 13. AD7884/AD7885 Typical Linearity Performance

Noise

In an A/D converter, noise exhibits itself as code uncertainty in dc applications and as the noise floor (in an FFT, for example) in ac applications.

In a sampling A/D converter like the AD7884/AD7885, all information about the analog input appears in the baseband from dc to 1/2 the sampling frequency. An antialiasing filter will remove unwanted signals above $f_S/2$ in the input signal but the converter wideband noise will alias into the baseband. In the AD7884/AD7885, this noise is made up of sample-and-hold noise and a/d converter noise. The sample-and-hold section contributes 51 μV rms and the ADC section contributes 59 μV rms. These add up to a total rms noise of 78 μV. This is the input referred noise in the ±3 V analog input range. When operating in the ±5 V input range, the input gain is reduced to −0.6. This means that the input referred noise is now increased by a factor of 1.66 to 120 μV rms.

Figure 14 shows a histogram plot for 5000 conversions of a dc input using the AD7884/AD7885 in the ±5 V input range. The analog input was set as close as possible to the center of a code transition. All codes other than the center code are due to the ADC noise. In this case, the spread is six codes.

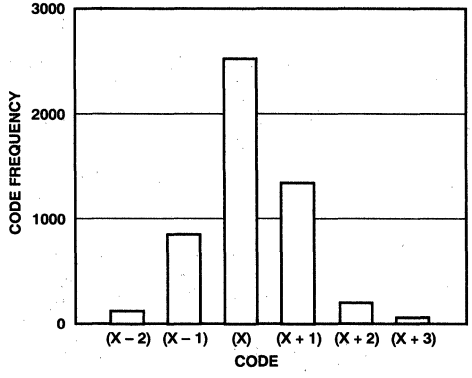

Figure 14. Histogram of 5000 Conversions of a DC Input

If the noise in the converter is too high for an application, it can be reduced by oversampling and digital filtering. This involves sampling the input at higher than the required word rate and then averaging to arrive at the final result. The very fast conversion time of the AD7884/AD7885 makes it very suitable for oversampling. For example, if the required input bandwidth is 40 kHz, the AD7884/AD7885 could be oversampled by a factor of 2. This yields a 3 dB improvement in the effective SNR performance. The noise performance in the ±5 volt input range is now effectively 85 μV rms and the resultant spread of codes for 2500 conversions will be four. This is shown in Figure 15.

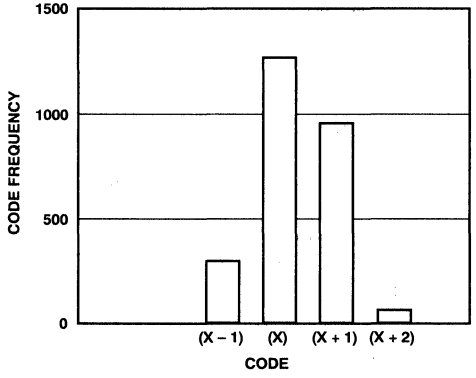

Figure 15. Histogram of 2500 Conversions of a DC Input Using a ×2 Oversampling Ratio

Dynamic Performance

With a combined conversion and acquisition time of 6 μs, the AD7884/AD7885 is ideal for wide bandwidth signal processing applications. Signal to (Noise + Distortion), Total Harmonic Distortion, Peak Harmonic or Spurious Noise and Intermodulation Distortion are all specified. Figure 16 shows a typical FFT plot of a 1.8 kHz, ±5 V input after being digitized by the AD7884/AD7885.

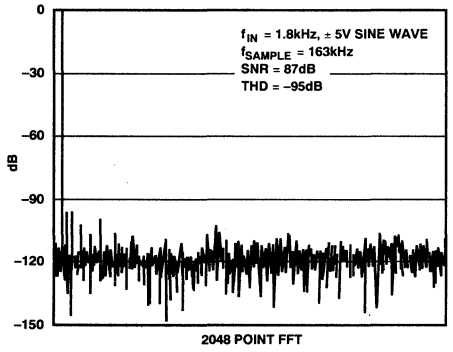

Figure 16. AD7884/AD7885 FFT Plot

Effective Number of Bits

The formula for SNR (see Terminology Section) is related to the resolution or number of bits in the converter. Rewriting the formula, below, gives a measure of performance expressed in effective number of bits (N).

$$N = (SNR - 1.76)/6.02$$

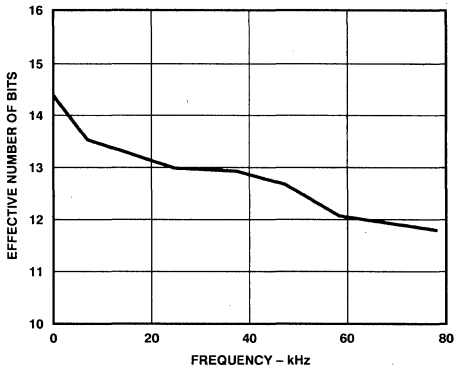

Figure 17. Effective Number of Bits vs. Frequency

The effective number of bits for a device can be calculated from its measured SNR. Figure 17 shows a typical plot of effective number of bits versus frequency for the AD7884. The sampling frequency is 166 kHz.

MICROPROCESSOR INTERFACING

The AD7884/AD7885 is designed on a high speed process which results in very fast interfacing timing (Data Access Time of 57 ns max). The AD7884 has a full 16-bit parallel bus, and the AD7885 has an 8-bit wide bus. The AD7884, with its parallel interface, is suited to 16-bit parallel machines whereas the AD7885, with its byte interface, is suited to 8-bit machines. Some examples of typical interface configurations follow.

AD7884 to MC68000 Interface

Figure 18 shows a general interface diagram for the MC68000, 16-bit microprocessor to the AD7884. In Figure 18, conversion is initiated by bringing $\overline{CSA}$ low (i.e., writing to the appropriate address). This allows the processor to maintain control over the complete conversion process. In some cases it may be more desirable to control conversion independent from the processor. This can be done by using an external sampling timer.

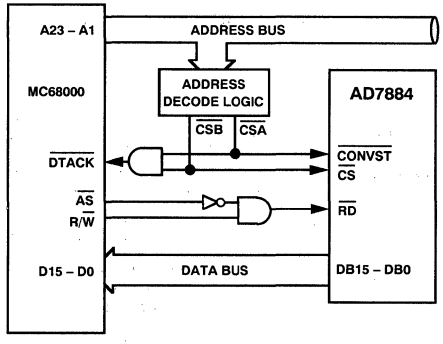

Figure 18. AD7884 to MC68000 Interface

Once conversion has been started, the processor must wait until it is completed before reading the result. There are two ways of ensuring this. The first way is to simply use a software delay to wait for 6.5 μs before bringing $\overline{CS}$ and $\overline{RD}$ low to read the data.

The second way is to use the $\overline{BUSY}$ output of the AD7884 to generate an interrupt in the MC68000. Because of the nature of its interrupts, the MC68000 requires additional logic (not shown in Figure 18) to allow it to be interrupted correctly. For full information on this, consult the MC68000 User's Manual.

AD7885 to 8088 Interface

The AD7885, with its byte (8 + 8) data format, is ideal for use with the 8088 microprocessor. Figure 19 is the interface diagram. Conversion is started by enabling $\overline{CSA}$. At the end of conversion, data is read into the processor. The read instructions are:

```
MOV AX, C001    Read 8 MSBs of data
MOV AX, C000    Read 8 LSBs of data
```

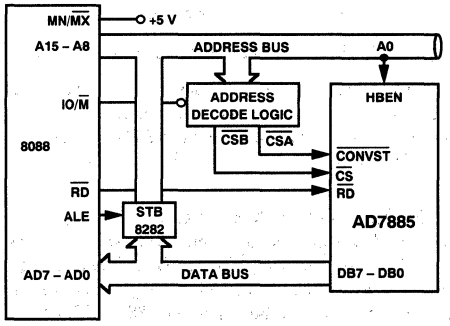

Figure 19. AD7885 to 8088 Interface

AD7884 to ADSP-2101 Interface

Figure 20 shows an interface between the AD7884 and the ADSP-2101. Conversion is initiated using a timer which allows very accurate control of the sampling instant. The AD7884 $\overline{BUSY}$ line provides an interrupt to the ADSP-2101 when conversion is completed. The $\overline{RD}$ pulse width of the processor can be programmed using the Data Memory Wait State Control Register. The result can then be read from the ADC using the following instruction:

MR0 = DM (ADC)

where MR0 is the ADSP-2101 MR0 register, and
ADC is the AD7884 address.

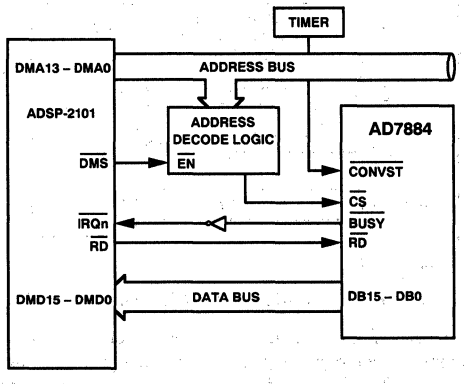

Figure 20. AD7884 to ADSP-2101 Interface

Stand-Alone Operation

If $\overline{CS}$ and $\overline{RD}$ are tied permanently low on the AD7884, then, when a conversion is completed, output data will be valid on the rising edge of $\overline{BUSY}$. This makes the device very suitable for stand-alone operation. All that is required to run the device is an external $\overline{CONVST}$ pulse which can be supplied by a sample timer. Figure 21 shows the AD7884 set up in this mode with the $\overline{BUSY}$ signal providing the clock for the 74HC574 3-state latches.

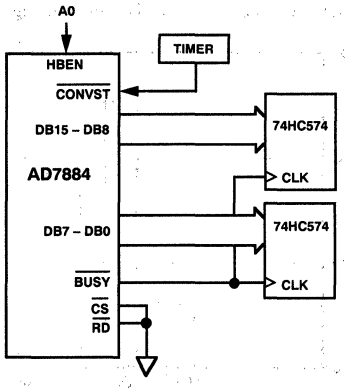

Figure 21. Stand-Alone Operation

Digital Feedthrough from an Active Bus

It is very important when using the AD7884/AD7885 in a microprocessor-based system to isolate the ADC data bus from the active processor bus while a conversion is being executed. This will yield the best noise performance from the ADC. Latches like the 74HC574 can be used to do this. If the device is connected directly to an active bus then the converter noise will typically increase by a factor of 30%.

ANALOG DEVICES

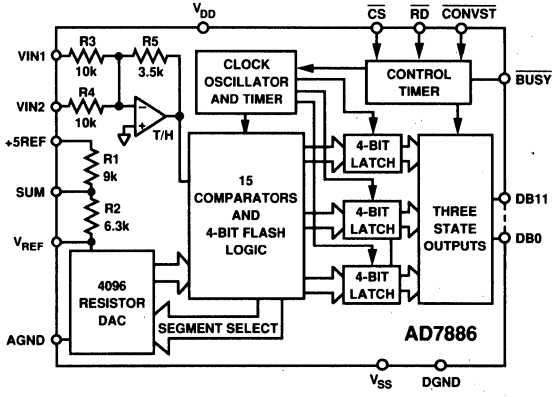
LC²MOS 12-Bit, 750 kHz/1 MHz, Sampling ADC

AD7886

FEATURES
750 kHz/1 MHz Throughput Rate
1 μs/750 ns Conversion Time
12-Bit No Missed Codes Over Temperature
67 dB SNR at 100 kHz Input Frequency
Low Power—250 mW typ
Fast Bus Access Time—57 ns max

APPLICATIONS
Digital Signal Processing
Speech Recognition and Synthesis
Spectrum Analysis
DSP Servo Control

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7886 is 12-bit ADC with a sample-and-hold amplifier offering high speed performance combined with low power dissipation. The AD7886 is a triple pass flash ADC, which uses 15 comparators in a 4-bit flash technique to achieve 12-bit accuracy in 1 μs/750 ns conversion time. An on-chip clock oscillator provides the appropriate timing for each of the three conversion stages eliminating the need for any external clocks. Acquisition time of the sample-and-hold amplifier gives a resulting throughput rate of 750 kHz/1 MHz.*

The AD7886 operates from ±5 V power supplies. Pin-strappable inputs offer a choice of three analog input ranges; 0 to 5 V, 0 to 10 V or ±5 V.

In addition to the traditional dc accuracy specifications such as linearity, offset and full-scale errors, the AD7886 is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The AD7886 has a high speed digital interface with three-state data outputs. Conversion control is provided by a $\overline{\text{CONVST}}$ input. Data access is controlled by $\overline{\text{CS}}$ and $\overline{\text{RD}}$ inputs, standard microprocessor signals. The data access time of less than 57 ns means that the AD7886 can interface directly to most modern microprocessors including DSP processors.

The AD7886 is fabricated in Analog Devices' Linear Compatible CMOS process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic.

The AD7886 is available in both a 28-pin DIP and in a 28-pin leaded chip carrier.

PRODUCT HIGHLIGHTS

1. Fast 1.33 μs/1 μs Throughput Time.
   Fast throughput time makes the AD7886 suitable for a wide range of data acquisition applications.
2. Dynamic Specifications for DSP Users.
   The AD7886 is specified for ac parameters, including signal-to-noise ratio, harmonic distortion and intermodulation distortion. Key digital timing parameters are also tested and guaranteed over the full operating temperature range.
3. Fast Microprocessor Interface.
   Standard control signals, $\overline{\text{CS}}$ and $\overline{\text{RD}}$, and fast bus access times make the AD7886 easy to interface to microprocessors.
4. Low Power.
   LC²MOS fabrication process gives low power dissipation of 250 mW.

	1000	**1000**	**1000**	ns max	

NOTES
[1]Timing specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]t_6 is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[3]t_7 and t_9 are derived from the measured time taken by the data outputs to change by 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the load capacitor, C_L. This means that the times, t_7 and t_9, quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.
Specifications subject to change without notice.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]If V_{SS} is open circuited with V_{DD} and AGND applied, the V_{SS} pin will be pulled positive, exceeding the Absolute Maximum Ratings. If this possibility exists, a Schottky diode from V_{SS} to DGND (cathode end to GND) ensures that the Absolute Maximum Ratings will be observed.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model[1, 2]	Temperature Range	SNR (dBs)	Integral Nonlinearity (LSBs)	Package Option[3]
AD7886JD	0°C to +70°C	65		D-28
AD7886KD	0°C to +70°C	67	±2.0	D-28
AD7886JP	0°C to +70°C	65		P-28A[2]
AD7886KP	0°C to +70°C	67	±2.0	P-28A[2]

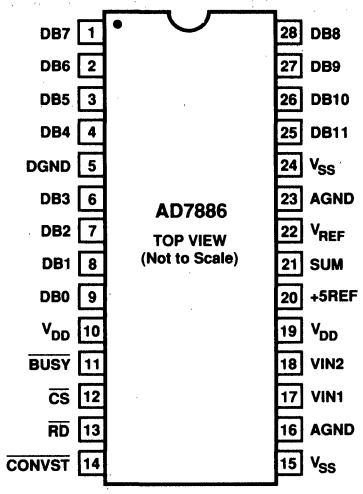
PIN FUNCTION DESCRIPTION

DIP Pin Number	Mnemonic	Description
Power Supply		
10 & 19	V_{DD}	Positive Power Supply, +5 V ± 5%. Both V_{DD} pins must be tied together.
15 & 24	V_{SS}	Negative Power Supply, −5 V ± 5%. Both V_{SS} pins must be tied together.
16 & 23	AGND	Analog Ground. Both AGND pins must be tied together.
5	DGND	Digital Ground.
Analog and Reference Inputs		
17 & 18	VIN	Analog Inputs, VIN1 and VIN2. The part can be pin strapped for any one of three analog input ranges;
20	+5REF	+5 V Reference input. This input is used in conjunction with SUM and V_{REF} inputs to scale an external +5 V reference to −3.5 V, the required reference for the part, see Figure 2.
21	SUM	Summing Point. This input is used in conjunction with +5REF and V_{REF} inputs to scale an external +5 V reference to −3.5 V, the required reference for the part, see Figure 2.
22	V_{REF}	Voltage Reference Input. The AD7886 is specified with V_{REF} = −3.5 V.
Interface and Control		
1–4, 6–9, 25–28	DB7–DB4 DB3–DB0 DB11–DB8	Three-state data outputs. These outputs are controlled by $\overline{CS}$ and $\overline{RD}$. DB11 is the Most Significant Bit (MSB).
11	$\overline{BUSY}$	$\overline{BUSY}$ Output indicates converter status. $\overline{BUSY}$ is low during conversion.
12	$\overline{CS}$	Chip Select Input. The device is selected when this input is low.
13	$\overline{RD}$	Read Input. This active low signal, in conjunction with $\overline{CS}$, is used to enable the output data three-state drivers.
14	$\overline{CONVST}$	Conversion Start Input. This input is used to start conversion.

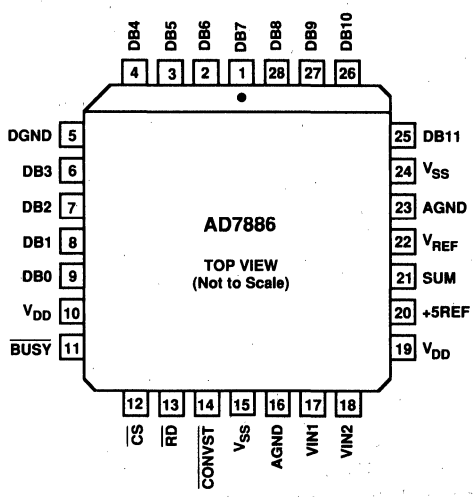
Range	Pin Strap	Signal Input
0 to 5 V	Connect VIN2 to VIN1	VIN1 & VIN2
0 to 10 V	Connect VIN2 to GND	VIN1
±5 V	Connect VIN2 to +5 V	VIN1

PIN CONFIGURATIONS

DIP



PLCC



TERMINOLOGY

Unipolar Offset Error

The ideal first code transition should occur when the analog input is 1 LSB above AGND. The deviation of the actual transition from that point is termed the offset error.

Bipolar Zero Error

The ideal midscale transition (i.e., 0111 1111 1111 to 1000 0000 0000 for the ±5 V range should occur when the analog input is at zero volts. Bipolar zero error is the deviation of the actual transition from that point.

Gain Error

In the unipolar mode, gain error is measured with respect to the first and last code transition points. The ideal difference between these points if FS−2 LSBs. For bipolar applications, the gain error is measured from the midscale transition to both the first and last code transitions. The ideal difference in this case is FS/2−1 LSB. The gain error is defined as the deviation between the ideal difference, given above, and the measured difference. For the bipolar case, there are two gain errors, the figure in the specification page represents the worst case. Ideal FS depends on the +5REF input; for the 0 to 5 V input, ideal FS = +5REF and for the 0 to 10 V and ±5 V ranges, ideal FS = 2 × +5REF.

CONVERTER DETAILS

The AD7886 is a triple-pass flash ADC which uses 15 comparators in a 4-bit flash technique to perform the 12-bit conversion procedure. Each of the 4096 quantization levels is realized internally with a precision resistor DAC.

The fifteen comparators first compare the analog input voltage to the V_{REF}/16 voltages of the resistor array. This determines the four most significant bits and selects 1 out of 16 voltage segments. The comparators are then switched to 15 subvoltages on that segment to determine the next four bits and select 1 out of 256 voltage segments. A further switching of the comparators to another 15 subvoltages produces the complete 12-bit conversion result. The 12 bits of data are then stored internally in a three-state output latch.

REFERENCE INPUT

The AD7886 operates from a −3.5 V reference which must be provided at the V_{REF} input. Two on-chip resistors for use with an external amplifier can be used for deriving −3.5 V from standard 5 V references. Figure 2 shows an example with the AD586 which a is a high performance voltage reference which exhibits excellent stability performance, 5 ppm/°C max. The external amplifier serves a second function of force/sensing the V_{REF} input. Force/sensing minimizes error contributions from

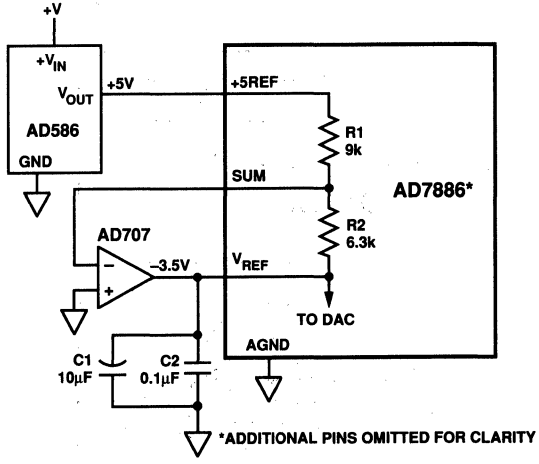


Figure 2. Typical Reference Circuitry

voltage or IR drops along the internal conductors. IR drops in the reference path cause a gain error, and typically the external amplifier reduces this error by 2 LSBs. In systems where a −3.5 V reference is available then it can be applied to the V_{REF} input directly causing a slight increase in gain error. A low op amp offset voltage is important as any offset voltage will add directly to the voltage that is being force/sensed. Suitable op amps for this application are precision op amps such as the AD705 or the AD707 which feature offset voltages of less than 100 μV.

Proper decoupling on the op amp output is important to suppress high speed transients during the conversion procedure. Note, connecting capacitors directly to op amp outputs can cause stability problems. However, the use of large capacitors, 10 μF in Figure 2, limits the open-loop bandwidth preventing any closed-loop oscillations.

TRACK-AND-HOLD AMPLIFIER

The analog input is sampled by an on-chip track-and-hold amplifier before being applied to the ADC. The 3dB bandwidth of this amplifier is typically 20 MHz which is much greater than the Nyquist limit of the ADC, so it can be used for undersampling applications. The track-and-hold amplifier acquires the input signal to 12-bit accuracy in less than 333 ns. The overall throughput time is equal to the conversion time plus the track/hold amplifier acquisition time which is 1.333 μs for the AD7886.

The operation of the track/hold amplifier is essentially transparent to the user. The track-to-hold transition occurs at the start of conversion on the falling edge of $\overline{\text{CONVST}}$. The conversion procedure does not start until the rising edge of $\overline{\text{CONVST}}$. The width of the $\overline{\text{CONVST}}$ pulse low time determines the track-to-hold settling time. The track/hold reverts back to the track mode at the end of conversion when $\overline{\text{BUSY}}$ has returned high.

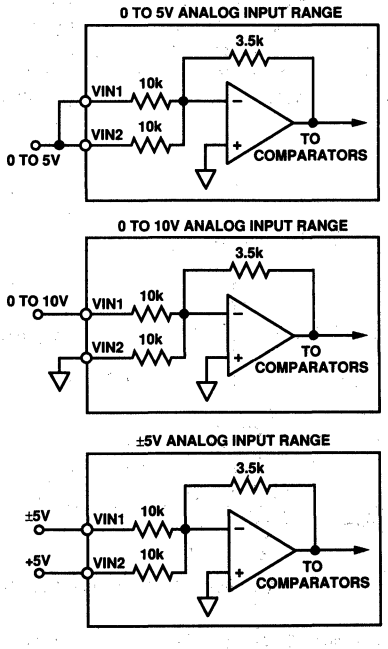

Figure 3. Analog Input Range Configurations

ANALOG INPUT RANGES

The AD7886 has three user selectable analog input ranges: 0 to 5 V, 0 to 10 V and ±5 V. Figure 3 shows how to configure the two analog inputs (VIN1 and VIN2) for these ranges.

UNIPOLAR OPERATION

Figure 4 shows a typical unipolar circuit for the AD7886. The ideal input/output characteristic is shown in Figure 5. The designed code transitions occur on integer multiples of 1 LSB.

The output code is natural binary with 1 LSB = FS/4096. FS is either +5 V or +10 V depending on how the analog inputs are configured.

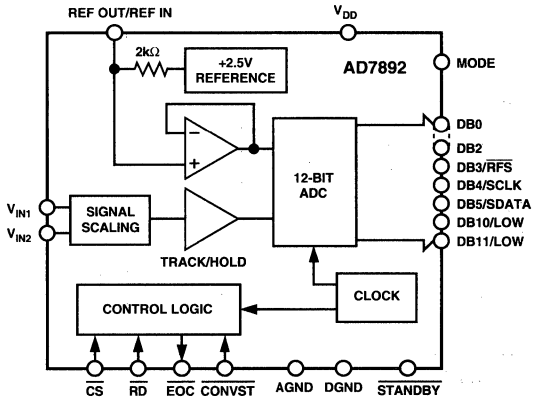
FEATURES

Fast 12-Bit ADC with 1.3 µs Conversion Time
600 kSPS Throughput Rate (AD7892-3)
500 kSPS Throughput Rate (AD7892-1, AD7892-2)
Single Supply Operation
On-Chip Track/Hold Amplifier
Selection of Input Ranges:
±10 V or ±5 V for AD7892-1
0 V to +2.5 V for AD7892-2
±2.5 V for AD7892-3
High Speed Serial and Parallel Interface
Low Power, 60 mW typ
Overvoltage Protection on Analog Inputs (AD7892-1 and AD7892-3)

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7892 is a high speed, low power, 12-bit A/D converter that operates from a single +5 V supply. The part contains a 1.3 µs successive approximation ADC, an on-chip track/hold amplifier, an internal +2.5 V reference and on-chip versatile interface structures that allow both serial and parallel connection to a microprocessor. The part accepts an analog input range of ±10 V or ±5 V (AD7892-1), 0 V to +2.5 V (AD7892-2) and ±2.5 V (AD7892-3). Overvoltage protection on the analog inputs for the AD7892-1 and AD7892-3 allows the input voltage to go to ±17 V or ±7 V respectively without damaging the ports.

The AD7892 offers a choice of two data output formats: a single, parallel, 12-bit word or serial data. Fast bus access times and standard control inputs ensure easy parallel interface to microprocessors and digital signal processors. A high speed serial interface allows direct connection to the serial ports of microcontrollers and digital signal processors.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the part is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The AD7892 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low-power CMOS logic. It is available in a 24-pin, 0.3" wide, plastic or hermetic DIP or in a 24-pin SOIC.

PRODUCT HIGHLIGHTS

1. The AD7892-3 features a conversion time of 1.3 µs and a track/hold acquisition time of 0.35 µs. This allows a throughput rate for the part up to 600 ksps. The AD7892-1 and AD7892-2 operate with throughput rates of 500 ksps.
2. The AD7892 operates from a single +5 V supply and consumes 60 mW typ making it ideal for low power and portable applications.
3. The part offers a high speed, flexible interface arrangement with parallel and serial interfaces for easy connection to microprocessors, microcontrollers and digital signal processors.

	30	30	ns max	

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are measured with tr = tf = 1 ns (10% to 90% of +5 V) and timed from a voltage level of +1.6 V.
[2]See Figures 2 and 3.
[3]Measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[4]These times are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.
[5]Assumes CMOS loads on data bits. With TTL loads, more current is drawn from the data lines and the $\overline{RD}$ to $\overline{CONVST}$ time needs to be extended to 300 ns min.
Specifications subject to change without notice.

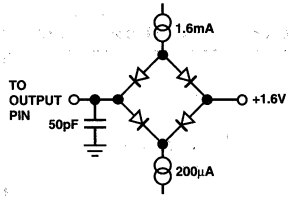

Figure 1. Load Circuit for Access Time and Bus Relinquish Time

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7892 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

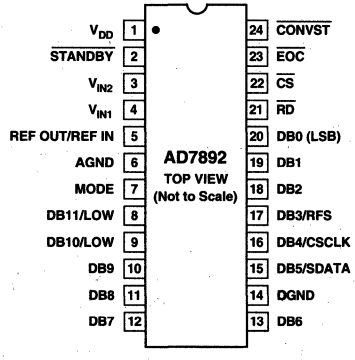
PIN FUNCTION DESCRIPTION

Pin No.	Mnemonic	Description
1	V_{DD}	Positive supply voltage, +5 V ± 5%.
2	$\overline{\text{STANDBY}}$	Standby Input. Logic Input. With this input at a logic high, the part is in its normal operating mode; with this input at a logic low, the part is placed in its standby or power-down mode, which reduces power consumption to 5 mW typical.
3	V_{IN2}	Analog Input 2. For the AD7892-1, this input either connects to AGND or to V_{IN1} to determine the analog input voltage range. With V_{IN2} connected to AGND on the AD7892-1, the analog input range at the V_{IN1} input is ±10 V. With V_{IN2} connected to V_{IN1} on the AD7892-1, the analog input range to the part is ±5 V. For the AD7892-2, the voltage range at the V_{IN1} input is referenced to the voltage applied to the V_{IN2} input. The allowable span for the V_{IN2} voltage is ±50 mV. With V_{IN2} at AGND on the AD7892-2, the analog input voltage range at the V_{IN1} input is 0 to +2.5 V. For the AD7892-3, this input should be connected to AGND.
4	V_{IN1}	Analog Input 1. The analog input voltage to be converted by the AD7892 is applied to this input. For the AD7892-1, the input voltage range is either ±5 V or ±10 V depending on where the V_{IN2} input is connected. For the AD7892-2, the voltage range on the V_{IN1} input is 0 V to +2.5 V with respect to the voltage appearing at the V_{IN2} input. For the AD7892-3, the voltage range on the V_{IN1} input is ±2.5 V.
5	REF OUT/REF IN	Voltage Reference Output/Input. The part can be used with either its own internal reference or with an external reference source. The on-chip +2.5 V reference is provided at this pin. When using this internal reference as the reference source for the part, REF OUT should be decoupled to AGND with a 0.1 µF disc ceramic capacitor. The output impedance of this reference source is typically 5.5 kΩ. When using an external reference source as the reference voltage for the part, the reference source should be connected to this pin. This overdrives the internal reference and provides the reference source for the part. The REF IN input is buffered on-chip but must be able to sink or source current through the resistor to the output of the on-chip reference. The nominal reference voltage for correct operation of the AD7892 is +2.5 V.
6	AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
7	MODE	Mode. Control input which determines the interface mode for the AD7892. With this pin at a logic low, the device is in its serial interface mode; with this pin at a logic high, the device is in its parallel interface mode.
8	DB11/LOW	Data Bit 11/Test Pin. When the device is in its parallel mode, this pin is Data Bit 11 (MSB), a three-state TTL-compatible output. When the device is in its serial mode, this is used as a test pin which must be tied to a logic low for correct operation of the AD7892
9	DB10/LOW	Data Bit 10/Test Pin. When the device is in its parallel mode, this pin is Data Bit 10, a three-state TTL-compatible output. When the device is in its serial mode, this is used as a test pin which must be tied to a logic low for correct operation of the AD7892.
10	DB9	Data Bit 9. Three-state TTL-compatible output. This output should be left unconnected when the device is in its serial mode.
11	DB8	Data Bit 8. Three-state TTL-compatible output. This output should be left unconnected when the device is in its serial mode.
12	DB7	Data Bit 7. Three-state TTL-compatible output. This output should be left unconnected when the device is in its serial mode.
13	DB6	Data Bit 6. Three-state TTL-compatible output. This output should be left unconnected when the device is in its serial mode.
14	DGND	Digital Ground. Ground reference for digital circuitry.
15	DB5/SDATA	Data Bit 5/Serial Data. When the device is in its parallel mode, this pin is Data Bit 5, a three-state TTL-compatible output. When the device is in its serial mode, this becomes the serial data output line. Sixteen bits of serial data are provided with four leading zeros preceding the 12-bits of valid data. Serial data is valid on the falling edge of SCLK for sixteen edges after $\overline{\text{RFS}}$ goes low. Output coding is 2s complement for AD7892-1 and AD7892-3 and straight (natural) binary for AD7892-2.

Pin No.	Mnemonic	Description
16	DB4/SCLK	Data Bit 4/Serial Clock. When the device is in its parallel mode, this pin is Data Bit 4, a three-state TTL-compatible output. When the device is in its serial mode, this becomes the serial clock pin, SCLK. SCLK is an input and an external serial clock must be provided at this pin to obtain serial data from the AD7892. Serial data is clocked out from the output shift register on the rising edges of SCLK after $\overline{RFS}$ goes low.
17	DB3/$\overline{RFS}$	Data Bit 3/Receive Frame Synchronization. When the device is in its parallel mode, this pin is Data Bit 3, a three-state TTL-compatible output. When the device is in its serial mode, this becomes the receive frame synchronization input with $\overline{RFS}$ provided externally to obtain serial data from the AD7892.
18	DB2	Data Bit 2. Three-state TTL-compatible output. This output should be left unconnected when the device is in its serial mode.
19	DB1	Data Bit 1. Three-state TTL-compatible output. This output should be left unconnected when the device is in its serial mode.
20	DB0	Data Bit 0 (LSB). Three-state TTL-compatible output. Output coding is 2s complement for AD7892-1 and AD7892-3 and straight (natural) binary for AD7892-2. This output should be left unconnected when the device is in its serial mode.
21	$\overline{RD}$	Read. Active low logic input which is used in conjunction with $\overline{CS}$ low to enable the data outputs.
22	$\overline{CS}$	Chip Select. Active low logic input which is used in conjunction with $\overline{RD}$ to enable he data outputs.
23	$\overline{EOC}$	End-of-Conversion. Active low logic output indicating converter status. The end of conversion is signified by a low-going pulse on this line. The duration of this $\overline{EOC}$ pulse is nominally 100 ns.
24	$\overline{CONVST}$	Convert Start. Logic Input. A low to high transition on this input puts the track/hold into its hold mode and starts conversion.

PIN CONFIGURATION

DIP and SOIC



CIRCUIT DESCRIPTION

The AD7892 is a fast, 12-bit single supply A/D converter. It provides the user with signal scaling, track/hold, reference, A/D converter and versatile interface logic functions on a single chip. The signal scaling on the AD7892-1 allows the part to handle either ±5 V or ±10 V input signals while operating from a single +5 V supply. The AD7892-2 handles a 0 to +2.5 V analog input range, while signal scaling on the AD7892-3 allows it to handle ±2.5 V input signals when operating from a single supply. The part requires a +2.5 V reference which can be provided from the part's own internal reference or from an external reference source.

Conversion is initiated on the AD7892 by pulsing the $\overline{\text{CONVST}}$ input. On the rising edge of $\overline{\text{CONVST}}$, the track/hold goes from track mode to hold mode and the conversion sequence is started. At the end of conversion (falling edge of $\overline{\text{EOC}}$), the track/hold returns to tracking mode and the acquisition time begins. Conversion time for the part is 1.3 µs (AD7892-3) and the track/hold acquisition time is 350 ns (AD7892-3). This allows the AD7892-3 to operate at throughput rates up to 600 ksps. The AD7892-1 and AD7892-2 are specified with a 1.6 µs conversion and 400 ns acquisition time allowing a throughput rate of 500 ksps.

Track/Hold Section

The track/hold amplifier on the AD7892 allows the ADC to accurately convert an input sine wave of full-scale amplitude to 12-bit accuracy. The input bandwidth of the track/hold is greater than the Nyquist rate of the ADC even when the ADC is operated at its maximum throughput rate of 600 kHz (i.e., the track/hold can handle input frequencies in excess of 300 kHz).

The track/hold amplifier acquires an input signal to 12-bit accuracy in less than 350 ns. The operation of the track/hold is essentially transparent to the user. The track/hold amplifier goes from its tracking mode to its hold mode on the rising edge of $\overline{\text{CONVST}}$. The aperture time for the track/hold (i.e., the delay time between the external $\overline{\text{CONVST}}$ signal and the track/hold actually going into hold) is typically 15 ns. At the end of conversion, the part returns to its tracking mode. The acquisition time of the track/hold amplifier begins at this point.

Reference Section

The AD7892 contains a single reference pin, labelled REF OUT/REF IN, which either provides access to the part's own +2.5 V reference or to which an external +2.5 V reference can be connected to provide the reference source for the part. The part is specified with a +2.5 V reference voltage. Errors in the reference source will result in gain errors in the AD7892's transfer function and will add to the specified full-scale errors on the part. On the AD7892-1 and AD7892-3, it will also result in an offset error injected in the attenuator stage.

The AD7892 contains an on-chip +2.5 V reference. To use this reference as the reference source for the AD7892, simply connect a 0.1 µF disc ceramic capacitor from the REF OUT/REF IN pin to AGND. The voltage that appears at this pin is internally buffered before being applied to the ADC. If this reference is required for use external to the AD7892, it should be buffered as the part has a FET switch in series with the reference output resulting in a source impedance for this output of 5.5 kΩ nominal. The tolerance on the internal reference is ±10 mV at 25°C with a typical temperature coefficient of 25 ppm/°C and a maximum error over temperature of ±25 mV.

If the application requires a reference with a tighter tolerance or the AD7892 needs to be used with a system reference, then the user has the option of connecting an external reference to this REF OUT/REF IN pin. The external reference will effectively overdrive the internal reference and thus provide the reference source for the ADC. The reference input is buffered before being applied to the ADC with the maximum input current is ±100 µA. Suitable reference sources for the AD7892 include the AD680, AD780 and REF43 precision +2.5 V references.

INTERFACING

The part provides two interface options, a 12-bit parallel interface and a three-wire serial interface. The required interface mode is selected via the MODE pin. The two interface modes are discussed in the following sections.

Parallel Interface Mode

The parallel interface mode is selected by tying the MODE input to a logic high. Figure 2 shows a timing diagram illustrating the operational sequence of the AD7892. The on-chip track/hold goes into hold mode, and conversion is initiated on the rising edge of the $\overline{\text{CONVST}}$ signal. When conversion is complete, the end of conversion line ($\overline{\text{EOC}}$) pulses low to indicate that new data is available in the AD7892's output register. This $\overline{\text{EOC}}$ line can be used to drive an edge-triggered interrupt of a microprocessor. The read operation should be completed 200 ns prior to the next rising edge of $\overline{\text{CONVST}}$. $\overline{\text{CS}}$ and $\overline{\text{RD}}$

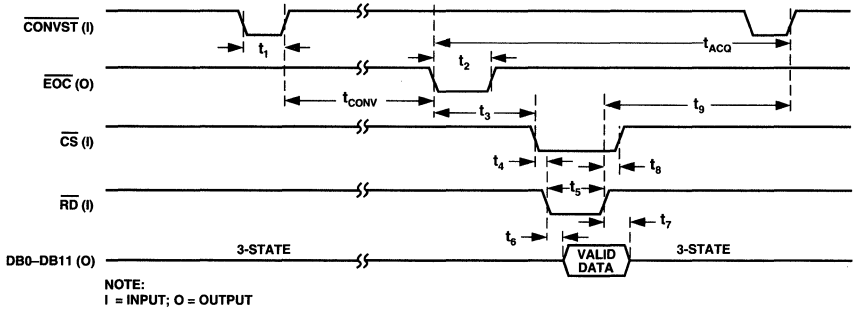


Figure 2. Parallel Mode Timing Diagram

going low accesses the 12-bit conversion result. In systems where the part is interfaced to a gate array or ASIC, this $\overline{EOC}$ pulse can be applied to the $\overline{CS}$ and $\overline{RD}$ inputs to latch data out of the AD7892 and into the gate array or ASIC. This eliminates the logic required in the gate array or ASIC to recognize the end of conversion and generate the read signal for the AD7892. To obtain optimum performance from the AD7892, it is not recommended to tie $\overline{CS}$ and $\overline{RD}$ permanently low as this keeps the three-state active during conversion.

Serial Interface Mode

The AD7892 is configured for serial mode interfacing by tying the MODE input low. It provides for a three-wire, serial link between the AD7892 and industry-standard microprocessors, microcontrollers and digital signal processors. SCLK and $\overline{RFS}$ of the AD7892 are inputs, and the AD7892's serial interface is designed for direct interface to systems that provide a serial clock input that is synchronized to the serial data output including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

Figure 3 shows the timing diagram for reading from the AD7892 in the serial interface mode. $\overline{RFS}$ goes low to access data from the AD7892. The serial clock input does not have to be continuous. The serial data can be accessed in a number of bytes. However, $\overline{RFS}$ must remain low for the duration of the data transfer operation. Sixteen bits of data are transmitted with four leading zeros followed by the 12-bit conversion result starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK. Old data is guaranteed to be valid for 5 ns after this edge. This is useful for high speed serial clocks where the access time of the part would not allow sufficient set-up time for the data to be accepted on the falling edge of the clock. In this case, care must be taken that $\overline{RFS}$ does not go just prior to a rising edge of SCLK. For slower serial clocks data is valid on the falling edge of SCLK. At the end of the read operation, the SDATA line is three-stated by a rising edge on either the SCLK of $\overline{RFS}$ inputs, whichever occurs first. Serial data cannot be read during conversion to avoid feedthrough problems from the serial clock to the conversion process. For optimum performance, a serial read should also be avoided within 400 ns of the rising edge of $\overline{CONVST}$ to avoid feedthrough into the track/hold during its acquisition time. The serial read should, therefore, occur between the end of conversion ($\overline{EOC}$ falling edge) and 400 ns prior to the next rising edge of $\overline{CONVST}$. This limits the maximum achievable throughput rate in serial mode (assuming 20 MHz serial clock) to 400 ksps for the AD7892-3 and 357 ksps for the AD7892-1 and AD7892-2.

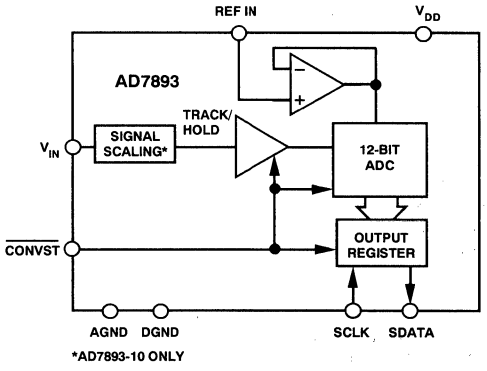
LC²MOS 12-Bit, Serial 6 µs ADC in 8-Pin Package

AD7893

FEATURES

Fast 12-Bit ADC with 6 µs Conversion Time
8-Pin Mini-DIP and SOIC
Single Supply Operation
High Speed, Easy-to-Use, Serial Interface
On-Chip Track/Hold Amplifier
Selection of Input Ranges
±10 V for AD7893-10
0 V to +2.5 V for AD7893-2
Low Power: 25 mW typ

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7893 is a fast, 12-bit ADC which operates from a single +5 V supply and is housed in a small 8-pin mini-DIP and 8-pin SOIC. The part contains a 6 µs successive approximation A/D converter, an on-chip track/hold amplifier, an on-chip clock and a high speed serial interface.

Output data from the AD7893 is provided via a high speed, serial interface port. This two-wire serial interface has a serial clock input and a serial data output with the external serial clock accessing the serial data from the part.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7893 is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The part accepts an analog input range of ±10 V (AD7893-10) or 0 V to +2.5 V (AD7893-2) and operates from a single +5 V supply consuming only 25 mW typical.

The AD7893 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a small, 8-pin, 0.3″ wide, plastic or hermetic dual-in-line package (mini-DIP) and in an 8-pin, small-outline IC (SOIC).

PRODUCT HIGHLIGHTS

1. Fast, 12-Bit ADC in 8-Pin Package
   The AD7893 contains a 6 µs ADC, a track/hold amplifier, control logic and a high speed serial interface, all in an 8-pin package. This offers considerable space saving over alternative solutions.
2. Low Power, Single Supply Operation
   The AD7893 operates from a single +5 V supply and consumes only 25 mW. This low power, single supply operation makes it ideal for battery-powered or portable applications.
3. High Speed Serial Interface
   The part provides high speed serial data and serial clock lines allowing for an easy, two-wire serial interface arrangement.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7893—SPECIFICATIONS (V_{DD} = +5 V, AGND = DGND = 0 V, REF IN = +2.5 V. All Specifications T_{MIN} to T_{MAX} unless otherwise noted.)

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

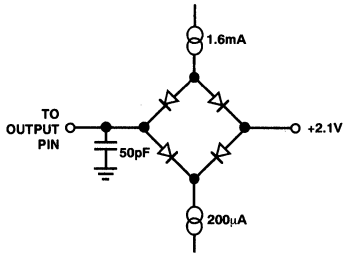

Figure 1. Load Circuit for Access Time and Bus Relinquish Time

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7893 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN FUNCTION DESCRIPTION

Pin No.	Pin Mnemonic	Description
1	REF IN	Voltage Reference Input. An external reference source should be connected to this pin to provide the reference voltage for the AD7893's conversion process. The REF IN input is buffered on-chip. The nominal reference voltage for correct operation of the AD7893 is +2.5 V.
2	V_{IN}	Analog Input Channel. The analog input range is ±10 V (AD7893-10), 0 to +5 V (AD7893-5) and 0 to +2.5 V (AD7893-2).
3	AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
4	SCLK	Serial Clock Input. An external serial clock is applied to this input to obtain serial data from the AD7893. A new serial data bit is clocked out on the rising edge of this serial clock and data is valid on the falling edge. The serial clock input should be taken low at the end of the serial data transmission.
5	SDATA	Serial Data Output. Serial data from the AD7893 is provided at this output. The serial data is clocked out by the rising edge of SCLK and is valid on the falling edge of SCLK. Sixteen bits of serial data are provided with four leading zeros followed by the 12-bits of conversion data. On the sixteenth falling edge of SCLK, the SDATA line is disabled (three-stated). Output data coding is twos complement for the AD7893-10 and straight binary for the AD7893-2 and AD7893-5.
6	DGND	Digital Ground. Ground reference for digital circuitry.
7	$\overline{\text{CONVST}}$	Convert Start. Edge-triggered logic input. On the falling edge of this input, the serial clock counter is reset to zero. On the rising edge of this input, the track/hold goes into its hold mode and conversion is initiated.
8	V_{DD}	Positive supply voltage, +5 V ± 5%.

TERMINOLOGY

Signal to (Noise + Distortion) Ratio
This is the measured ratio of signal to (noise + distortion) at the output of the A/D converter. The signal is the rms amplitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio is dependent upon the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to (noise + distortion) ratio for an ideal N-bit converter with a sine wave input is given by:

$$\textit{Signal to (Noise + Distortion)} = (6.02N + 1.76)\ dB$$

Thus for a 12-bit converter, this is 74 dB.

Total Harmonic Distortion
Total harmonic distortion (THD) is the ratio of the rms sum of harmonics to the fundamental. For the AD7893, it is defined as:

$$THD(dB) = 20\ log\ \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonics.

Peak Harmonic or Spurious Noise
Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor, it will be a noise peak.

Intermodulation Distortion
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither *m* or *n* are equal to zero. For example, the second order terms include (fa + fb) and (fa − fb), while the third order terms include (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb).

The AD7893 is tested using the CCIF standard where two input frequencies near the top end of the input bandwidth are used. In this case, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves, while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

Relative Accuracy
Relative accuracy or endpoint nonlinearity is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function.

Differential Nonlinearity
This is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Positive Full-Scale Error (AD7893-10)
This is the deviation of the last code transition (01 . . . 110 to 01 . . . 111) from the ideal (4 × REF IN − 1 LSB) after the Bipolar Zero Error has been adjusted out.

Positive Full-Scale Error (AD7893-5)
This is the deviation of the last code transition (11 . . . 110 to 11 . . . 111) from the ideal (2 × REF IN − 1 LSB) after the Unipolar Offset Error has been adjusted out.

Positive Full-Scale Error (AD7893-2)
This is the deviation of the last code transition (11 . . . 110 to 11 . . . 111) from the ideal (REF IN − 1 LSB) after the Unipolar Offset Error has been adjusted out.

Bipolar Zero Error (AD7893-10)
This is the deviation of the midscale transition (all 0s to all 1s) from the ideal 0 V (AGND).

Unipolar Offset Error (AD7893-2, AD7893-5)
This is the deviation of the first code transition (00 . . . 000 to 00 . . . 001) from the ideal 1 LSB.

Negative Full-Scale Error (AD7893-10)
This is the deviation of the first code transition (10 . . . 000 to 10 . . . 001) from the ideal (−4 × REF IN + 1 LSB) after Bipolar Zero Error has been adjusted out.

Track/Hold Acquisition Time
Track/Hold acquisition time is the time required for the output of the track/hold amplifier to reach its final value, within ±1/2 LSB, after the end of conversion (the point at which the track/hold returns to track mode). It also applies to situations where there is a step input change on the input voltage applied to the V_{IN} input of the AD7893. This means that the user must wait for the duration of the track/hold acquisition time after the end of conversion or after a step input change to V_{IN} before starting another conversion, to ensure that the part operates to specification.

CONVERTER DETAILS

The AD7893 is a fast, 12-bit single supply A/D converter. It provides the user with signal scaling (AD7893-10), track/hold, A/D converter and serial interface logic functions on a single chip. The A/D converter section of the AD7893 consists of a conventional successive-approximation converter based around an R-2R ladder structure. The signal scaling on the AD7893-10 and AD7893-5 allows the part to handle ±10 V and 0 to +5 V input signals respectively while operating from a single +5 V supply. The AD7893-2 accepts an analog input range of 0 V to +2.5 V. The part requires an external +2.5 V reference. The reference input to the part is buffered on-chip.

A major advantage of the AD7893 is that it provides all of the above functions in an 8-pin package, either 8-pin mini-DIP or SOIC. This offers the user considerable spacing saving advantages over alternative solutions. The AD7893 consumes only 25 mW typical making it ideal for battery-powered applications.

Conversion is initiated on the AD7893 by pulsing the $\overline{\text{CONVST}}$ input. On the rising edge of $\overline{\text{CONVST}}$, the on-chip track/hold goes from track to hold mode and the conversion sequence is started. The conversion clock for the part is generated internally using a laser-trimmed clock oscillator circuit. Conversion time for the AD7893 is 6 μs and the track/hold acquisition time is 1.5 μs. To obtain optimum performance from the part, the read operation should not occur during the conversion or during 600 ns prior to the next conversion. This allows the part to operate at throughput rates up to 117 kHz and achieve data sheet specifications. The part can operate at higher throughput rates (up to 133 kHz) with slightly degraded performance (see Timing and Control section).

CIRCUIT DESCRIPTION

Analog Input Section

The AD7893 is offered as three part types, the AD7893-10 which handles a ±10 V input voltage range, the AD7893-5 which handles a 0 to +5 V input range and the AD7893-2 which handles a 0 V to +2.5 V input voltage range.

Figure 2 shows the analog input section for the AD7893-10 and AD7893-5. The analog input range of the AD7893-10 is ±10 V into an input resistance of typically 33 kΩ. The input range on the AD7893-5 is 0 to +5 V into an input resistance of typically 11 kΩ. This input is benign with no dynamic charging currents as the resistor stage is followed by a high input impedance stage of the track/hold amplifier. For the AD7893-10, R1 = 30 kΩ, R2 = 7.5 kΩ and R3 = 10 kΩ. For the AD7893-5, R1 and R3 = 5 kΩ while R2 is open-circuit.

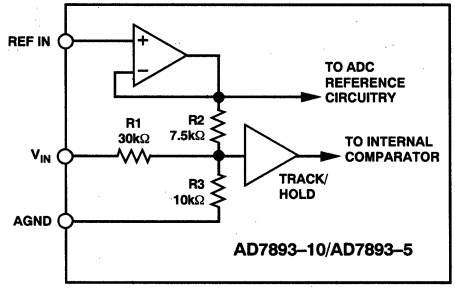

Figure 2. AD7893-10/AD7893-5 Analog Input Structure

For the AD7893-10, the designed code transitions occur on successive integer LSB values (i.e., 1 LSB, 2 LSBs, 3 LSBs ...). Output coding is 2s complement binary with 1 LSB = FS/4096 = 20 V/4096 = 4.88 mV. The ideal input/output transfer function for the AD7893-10 is shown in Table I.

Table I. Ideal Input/Output Code Table for the AD7893-10

Analog Input[1]	Digital Output Code Transition
+FSR/2 − 1 LSB[2] (9.995117)	011 . . . 110 to 011 . . . 111
+FSR/2 − 2 LSBs (9.990234)	011 . . . 101 to 011 . . . 110
+FSR/2 − 3 LSBs (9.985352)	011 . . . 100 to 011 . . . 101
AGND + 1 LSB (0.004883)	000 . . . 000 to 000 . . . 001
AGND (0.000000)	111 . . . 111 to 000 . . . 000
AGND − 1 LSB (−0.004883)	111 . . . 110 to 111 . . . 111
−FSR/2 + 3 LSBs (−9.985352)	100 . . . 010 to 100 . . . 011
−FSR/2 + 2 LSBs (−9.990234)	100 . . . 001 to 100 . . . 010
−FSR/2 + 1 LSB (−9.995117)	100 . . . 000 to 100 . . . 001

NOTES
[1]FSR is full-scale range and is 20 V with REF IN = +2.5 V.
[2]1 LSB = FSR/4096 = 4.883 mV with REF IN = +2.5 V.

For the AD7893-5, the designed code transitions again occur on successive integer LSB values. Output coding is straight (natural) binary with 1 LSB = FS/4096 = 5 V/4096 = 1.22 mV. The ideal input/output transfer function for the AD7893-5 is shown in Table II.

The analog input section for the AD7893-2 contains no biasing resistors and the V_{IN} pin drives the input to the track/hold amplifier directly. The analog input range is 0 V to +2.5 V into a high impedance stage with an input current of less than 500 nA. This input is benign with no dynamic charging currents. Once again, the designed code transitions occur on successive integer LSB values. Output coding is straight (natural) binary with 1 LSB = FS/4096 = 2.5 V/4096 = 0.61 mV. Table II also shows the ideal input/output transfer function for the AD7893-2.

Table II. Ideal Input/Output Code Table for AD7893-2/AD7893-5

Analog Input[1]	Digital Output Code Transition
+FSR − 1 LSB[2]	111 . . . 110 to 111 . . . 111
+FSR − 2 LSB	111 . . . 101 to 111 . . . 110
+FSR − 3 LSB	111 . . . 100 to 111 . . . 101
AGND + 3 LSB	000 . . . 010 to 000 . . . 011
AGND + 2 LSB	000 . . . 001 to 000 . . . 010
AGND + 1 LSB	000 . . . 000 to 000 . . . 001

NOTES
[1]FSR is Full Scale Range and is 5 V for AD7893-5 and 2.5 V for AD7893-2 with REF IN = +2.5 V.
[2]1 LSB = FSR/4096 and is 1.22 mV for AD7893-5 and 0.61 mV for AD7893-2 with REF IN = +2.5 V.

Track/Hold Section

The track/hold amplifier on the analog input of the AD7893 allows the ADC to accurately convert an input sine wave of full-scale amplitude to 12-bit accuracy. The input bandwidth of the track/hold is greater than the Nyquist rate of the ADC even when the ADC is operated at its maximum throughput rate of 117 kHz (i.e., the track/hold can handle input frequencies in excess of 58 kHz).

The track/hold amplifier acquires an input signal to 12-bit accuracy in less than 1.5 μs. The operation of the track/hold is essentially transparent to the user. The track/hold amplifier goes from its tracking mode to its hold mode at the start of conversion (i.e., the rising edge of $\overline{\text{CONVST}}$). The aperture time for the track/hold (i.e. the delay time between the external $\overline{\text{CONVST}}$ signal and the track/hold actually going into hold) is typically 15 ns. At the end of conversion (6 μs after the rising edge of $\overline{\text{CONVST}}$) the part returns to its tracking mode. The acquisition time of the track/hold amplifier begins at this point.

Reference Input

The reference input to the AD7893 is buffered on-chip with a maximum reference input current of 1 μA. The part is specified with a +2.5 V reference input voltage. Errors in the reference source will result in gain errors in the AD7893's transfer function and will add to the specified full-scale errors on the part. On the AD7893-10 it will also result in an offset error injected in the attenuator stage. Suitable reference sources for the AD7893 include the AD780 and AD680 precision +2.5 V references.

Timing and Control Section

Figure 4 shows the timing and control sequence required to obtain optimum performance from the AD7893. In the sequence shown, conversion is initiated on the rising edge of $\overline{\text{CONVST}}$ and new data from this conversion is available in the output register of the AD7893 6 μs later. Once the read operation has taken place, a further 600 ns should be allowed before the next rising edge of $\overline{\text{CONVST}}$ to optimize the settling of the track/hold amplifier before the next conversion is initiated. With the serial clock frequency at its maximum of 8.33 MHz, the achievable throughput rate for the part is 6 μs (conversion time) plus 1.92 μs (read time) plus 0.6 μs (acquisition time). This results in a minimum throughput time of 8.52 μs (equivalent to a throughput rate of 117 kHz).

The read operation consists of sixteen serial clock pulses to the output shift register of the AD7893. After sixteen serial clock pulses the shift register is reset and the SDATA line is three-stated. If there are more serial clock pulses after the sixteenth clock, the shift register will be moved on past its reset state. However, the shift register will be reset again on the falling edge of the $\overline{\text{CONVST}}$ signal to ensure that the part returns to a known state every conversion cycle. As a result, a read operation from the output register should not straddle across the falling edge of $\overline{\text{CONVST}}$ as the output shift register will be reset in the middle of the read operation and the data read back into the microprocessor will appear invalid.

The throughput rate of the part can be increased by reading data during conversion or during the acquisition time. If the data is read during conversion, a throughput time of 6 μs (conversion time) plus 1.5 μs is achieved. This minimum throughput time of 7.5 μs is achieved with a slight reduction in performance from the AD7893. The signal to (noise + distortion) number is likely to degrade by approximately 1.5 dB while the code flicker from the part will also increase (see AD7893 PERFORMANCE section).

Because the AD7893 is provided in an 8-pin package to minimize board space, the number of pins available for interfacing is very limited. As a result, no status signal is provided from the AD7893 to indicate when conversion is complete. In many applications this will not be a problem as the data can be read from the AD7893 during conversion or after conversion. However, applications which want to achieve optimum performance from the AD7893 will have to ensure that the data read does not occur during conversion or during 600 ns prior to the rising edge of $\overline{\text{CONVST}}$. This can be achieved in either of two ways. The first is to ensure in software that the read operation is not initiated until 6 μs after the rising edge of $\overline{\text{CONVST}}$. This will only be possible if the software knows when the $\overline{\text{CONVST}}$ command is issued. The second scheme would be to use the $\overline{\text{CONVST}}$ signal as both the conversion start signal and an interrupt signal. The simplest way to do this would be to generate a square wave signal for $\overline{\text{CONVST}}$ with high and low times of 6 μs (see Figure 4). Conversion is initiated on the rising edge of $\overline{\text{CONVST}}$. The falling edge of $\overline{\text{CONVST}}$ occurs 6 μs later and can be used as either an active low or falling edge-triggered interrupt signal to tell the processor to read the data from the

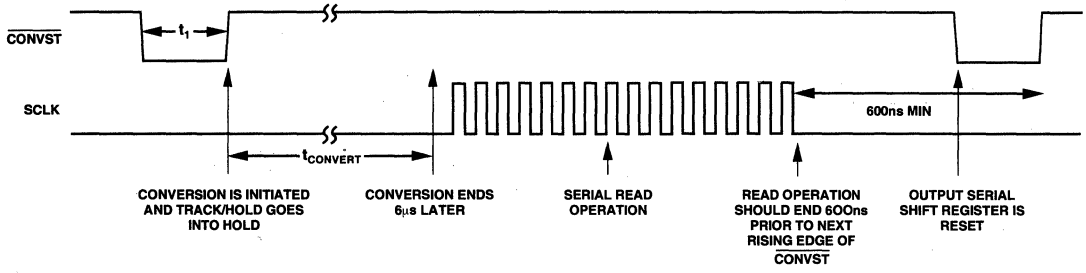

Figure 3. Timing Sequence for Optimum Performance from the AD7893

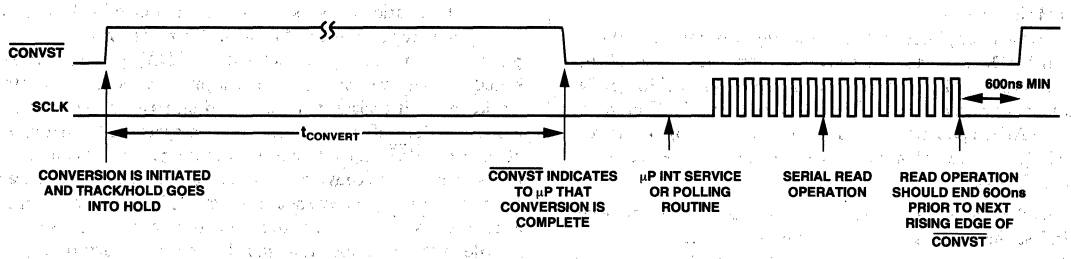

Figure 4. CONVST Used as Status Signal

AD7893. Provided the read operation is completed 600 ns before the rising edge of CONVST, the AD7893 will operate to specification.

This scheme limits the throughput rate to 12 µs minimum. However, depending upon the response time of the microprocessor to the interrupt signal and the time taken by the processor to read the data, this may the fastest which the system could have operated. In any case, the CONVST signal does not have to have a 50:50 duty cycle. This can be tailored to optimize the throughput rate of the part for a given system.

Alternatively, the CONVST signal can be used as a normal narrow pulse width. The rising edge of CONVST can be used as an active high or rising edge-triggered interrupt. A software delay of 6 µs can then be implemented before data is read from the part.

Serial Interface

The serial interface to the AD7893 consists of just two wires, a serial clock input (SCLK) and the serial data output (SDATA). This allows for an easy-to-use interface to most microcontrollers, DSP processors and shift registers.

Figure 5 shows the timing diagram for the read operation to the AD7893. The serial clock input (SCLK) provides the clock source for the serial interface. Serial data is clocked out from the SDATA line on the rising edge of this clock and is valid on the falling edge of SCLK. Sixteen clock pulses must be provided to the part to access to full conversion result. The AD7893 provides four leading zeros followed by the 12-bit conversion result starting with the MSB (DB11). The last data bit to be clocked out on the final rising clock edge is the LSB (DB0). On the sixteenth falling edge of SCLK, the SDATA line is disabled (three-stated). After this last bit has been clocked out, the SCLK input should return low and remain low until the next serial data read operation. If there are extra clock pulses after the sixteenth clock, the AD7893 will start over again with outputting data from its output register and the data bus will no longer be three-stated even when the clock stops. Provided the serial clock has stopped before the next falling edge of CONVST, the AD7893 will continue to operate correctly with the output shift register being reset on the falling edge of CONVST. However, the SCLK line must be low when CONVST goes low in order to reset the output shift register correctly.

The serial clock input does not have to be continuous during the serial read operation. The sixteen bits of data (four leading zeros and 12 bit conversion result) can be read from the AD7893 in a number of bytes. However, the SCLK input must remain low between the two bytes.

Normally, the output register is updated at the end of conversion. However, if a serial read from the output register is in progress when conversion is complete, the updating of the output register is deferred. In this case, the output register is updated when the serial read is completed. If the serial read has not been completed before the next falling edge of CONVST, then the output register will be updated on the falling edge of CONVST and the output shift register count is reset. In applications where the data read has been started and not completed before the falling edge of CONVST, the user must provide a CONVST pulse width of greater than 1.5 µs to ensure correct setup of the AD7893 before the next conversion is initiated. In

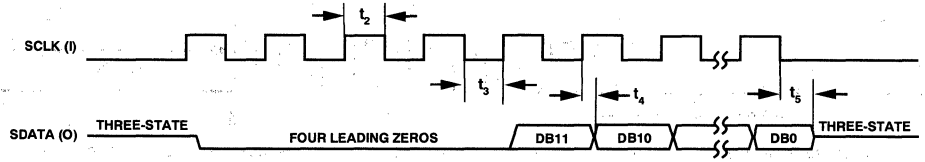

Figure 5. Data Read Operation

applications where the output update takes place either at the end of conversion or at the end of a serial read which is completed 1.5 μs before the rising edge of $\overline{\text{CONVST}}$, the normal pulse width of 50 ns minimum applies to $\overline{\text{CONVST}}$.

The AD7893 counts the serial clock edges to know which bit from the output register should be placed on the SDATA output. To ensure that the part does not lose synchronization, the serial clock counter is reset on the falling edge of the $\overline{\text{CONVST}}$ input provided the SCLK line is low. The user should ensure that a falling edge on the $\overline{\text{CONVST}}$ input does not occur, while a serial data read operation is in progress.

MICROPROCESSOR/MICROCONTROLLER INTERFACE

The AD7893 provides a two-wire serial interface which can be used for connection to the serial ports of DSP processors and microcontrollers. Figures 6 through 9 show the AD7893 interfaced to a number of different microcontrollers and DSP processors. The AD7893 accepts an external serial clock and as a result, in all interfaces shown here, the processor/controller is configured as the master, providing the serial clock, with the AD7893 configured as the slave in the system.

AD7893–8051 Interface

Figure 6 shows an interface between the AD7893 and the 8XC51 microcontroller. The 8XC51 is configured for its Mode 0 serial interface mode. The diagram shows the simplest form of the interface where the AD7893 is the only part connected to the serial port of the 8XC51 and, therefore, no decoding of the serial read operations is required. It also makes no provisions for monitoring when conversion is complete on the AD7893.

Either of these two tasks can readily be accomplished with minor modifications to the interface. To chip select the AD7893 in systems where more than one device is connected to the 8XC51's serial port, a port bit, configured as an output, from one of the 8XC51's parallel ports can be used to gate on or off the serial clock to the AD7893. A simple AND function on this port bit and the serial clock from the 8XC51 will provide this function. The port bit should be high to select the AD7893 and low when it is not selected.

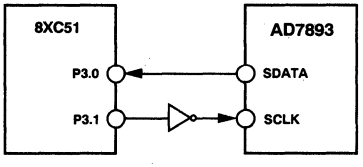

Figure 6. AD7893 to 8XC51 Interface

To monitor the conversion time on the AD7893 a scheme such as outlined previously with $\overline{\text{CONVST}}$ can be used. This can be implemented in two ways. One is to connect the $\overline{\text{CONVST}}$ line to another parallel port bit which is configured as an input. This port bit can then be polled to determine when conversion is complete. An alternative is to use an interrupt driven system in which case the $\overline{\text{CONVST}}$ line should be connected to the INT1 input of the 8XC51.

The serial clock rate from the 8XC51 is limited to significantly less than the allowable input serial clock frequency with which the AD7893 can operate. As a result, the time to read data from the part will actually be longer than the conversion time of the part. This means that the AD7893 cannot run at its maximum throughput rate when used with the 8XC51.

AD7893–68HC11 Interface

An interface circuit between the AD7893 and the 68HC11 microcontroller is shown in Figure 7. For the interface shown, the 68HC11 SPI port is used and the 68HC11 is configured in its single-chip mode. The 68HC11 is configured in the master mode with its CPOL bit set to a logic zero and its CPHA bit set to a logic one. As with the previous interface, the diagram shows the simplest form of the interface where the AD7893 is the only part connected to the serial port of the 68HC11 and, therefore, no decoding of the serial read operations is required. It also makes no provisions for monitoring when conversion is complete on the AD7893.

Once again, either of these two tasks can readily be accomplished with minor modifications to the interface. To chip select the AD7893 in systems where more than one device is connected to the 68HC11's serial port, a port bit, configured as an output, from one of the 68HC11's parallel ports can be used to gate on or off the serial clock to the AD7893. A simple AND function on this port bit and the serial clock from the 68HC11 will provide this function. The port bit should be high to select the AD7893 and low when it is not selected.

To monitor the conversion time on the AD7893 a scheme, such as outlined in the previous interface with $\overline{\text{CONVST}}$, can be used. This can be implemented in two ways. One is to connect the $\overline{\text{CONVST}}$ line to another parallel port bit which is configured as an input. This port bit can then be polled to determine when conversion is complete. An alternative is to use an interrupt driven system in which case the $\overline{\text{CONVST}}$ line should be connected to the $\overline{\text{IRQ}}$ input of the 68HC11.

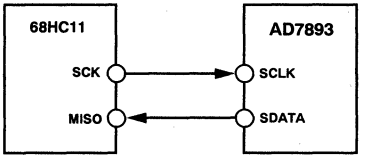

Figure 7. AD7893 to 68HC11 Interface

The serial clock rate from the 68HC11 is limited to significantly less than the allowable input serial clock frequency with which the AD7893 can operate. As a result, the time to read data from the part will actually be longer than the conversion time of the part. This means that the AD7893 cannot run at its maximum throughput rate when used with the 68HC11.

AD7893–ADSP-2105 Interface

An interface circuit between the AD7893 and the ADSP-2105 DSP processor is shown in Figure 8. In the interface shown, the RFS1 output from the ADSP-2105's SPORT1 serial port is used to gate the serial clock (SCLK1) of the ADSP-2105 before it is applied to the SCLK input of the AD7893. The RFS1 output is configured for active high operation. The interface ensures a noncontinuous clock for the AD7893's serial clock input, with only sixteen serial clock pulses provided and the serial clock line of the AD7893 remaining low between data transfers. The SDATA line from the AD7893 is connected to the DR1 line of the ADSP-2105's serial port.

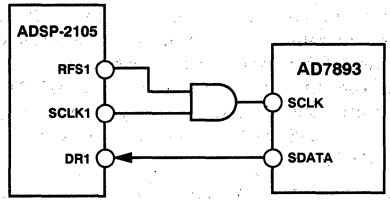

Figure 8. AD7893 to ADSP-2105 Interface

The timing relationship between the SCLK1 and RFS1 outputs of the ADSP-2105 are such that the delay between the rising edge of the SCLK1 and the rising edge of an active high RFS1 is up to 25 ns. There is also a requirement that data must be setup 10 ns prior to the falling edge of the SCLK1 to be read correctly by the ADSP-2105. The data access time for the AD7893 is 50 ns from the rising edge of its SCLK input. Assuming a 10 ns propagation delay through the external AND gate, the high time of the SCLK1 output of the ADSP-2105 must be $\geq (50 + 25 + 10 + 10)$ ns, i.e., ≥ 95 ns. This means that the serial clock frequency with which the interface of Figure 13 can work with is limited to 5.26 MHz.

An alternative scheme is to configure the ADSP-2105 such that it accepts an external serial clock. In this case, an external noncontinuous serial clock is provided which drives the serial clock inputs of both the ADSP-2105 and the AD7893. In this scheme, the serial clock frequency is limited to 5 MHz by the ADSP-2105.

To monitor the conversion time on the AD7893 a scheme, such as outlined in previous interfaces with $\overline{\text{CONVST}}$, can be used. This can be implemented by connecting the $\overline{\text{CONVST}}$ line directly to the $\overline{\text{IRQ2}}$ input of the ADSP-2105.

AD7893–DSP56000 Interface

Figure 9 shows an interface circuit between the AD7893 and the DSP56000 DSP processor. The DSP5600 is configured for normal mode asynchronous operation with gated clock. It is also set up for a 16-bit word with the gated serial clock being generated by the DSP56000 and appears on the SC0 pin. The SC0 pin should be configured as an output by setting bit SCD0 to 1. In this mode, the DSP56000 provides sixteen serial clock pulses to the AD7893 in a serial read operation. The DSP56000 assumes valid data on the first falling edge of SCK so the interface is simply two-wire as shown in Figure 9.

To monitor the conversion time on the AD7893 a scheme, such as outlined in previous interface examples with $\overline{\text{CONVST}}$, can be used. This can be implemented by connecting the $\overline{\text{CONVST}}$ line directly to the $\overline{\text{IRQA}}$ input of the DSP56000.

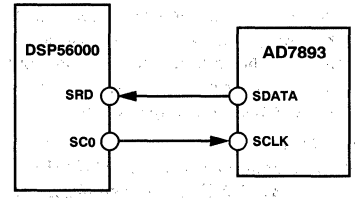

Figure 9. AD7893 to DSP56000 Interface

AD7893 PERFORMANCE

Figure 10 shows a histogram plot for 8192 conversions of a dc input using the AD7893. The analog input was set at the center of a code transition. The timing and control sequence used was as per Figure 3 where the optimum performance of the ADC was achieved. It can be seen that almost all the codes appear in the one output bin indicating very good noise performance from the ADC. The rms noise performance for the AD7893-2 for the above plot was 87 μV. Since the analog input range, and hence LSB size, on the AD7893-10 is eight times what it is for the AD7893-2, the same output code distribution results in an output rms noise of 700 μV for the AD7893-10.

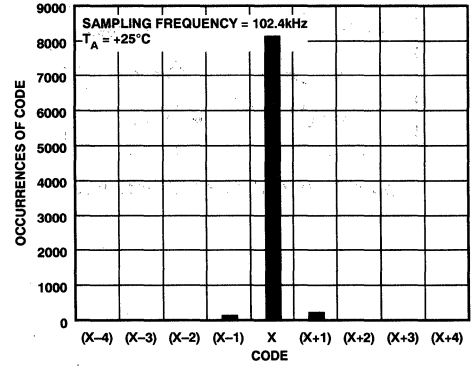

Figure 10. Histogram of 8192 Conversions of a DC Input

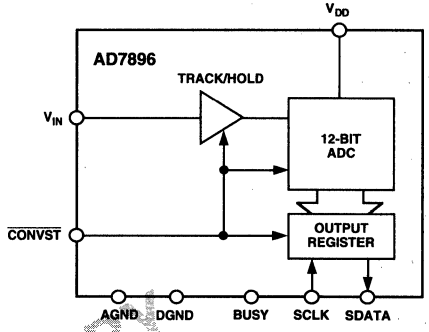
3 V, LC²MOS 12-Bit, Serial 8 µs ADC in 8-Pin Package

AD7896*

FEATURES

Fast 12-Bit ADC with 8 µs Conversion Time
8-Pin Mini-DIP and SOIC
Single 3 V Supply Operation
High Speed, Easy-to-Use, Serial Interface
On-Chip Track/Hold Amplifier
Analog Input Range is 0 V to V_{DD}
High Input Impedance
Low Power: 10 mW typ

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7896 is a fast, 12-bit ADC which operates from a single +3 V supply and is housed in a small 8-pin mini-DIP and 8-pin SOIC. The part contains an 8 µs successive approximation A/D converter, an on-chip track/hold amplifier, an on-chip clock and a high speed serial interface.

Output data from the AD7896 is provided via a high speed, serial interface port. This two-wire serial interface has a serial clock input and a serial data output with the external serial clock accessing the serial data from the part.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7896 is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

The part accepts an analog input range of 0 V to V_{DD} and operates from a single +3 V supply consuming only 10 mW typical. The V_{DD} input is also used as the reference for the part so that no external reference is required.

The AD7896 features a high sampling rate mode and, for low power applications, a proprietary automatic power down mode where the part automatically goes into power down once conversion is complete and "wakes up" before the next conversion cycle.

The AD7896 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a small, 8-pin, 0.3" wide, plastic or hermetic dual-in-line package (mini-DIP) and in an 8-pin, small outline IC (SOIC).

***Patent pending.**

PRODUCT HIGHLIGHTS

1. Complete, 12-bit ADC in 8-Pin Package
   The AD7896 contains an 8 µs ADC, a track/hold amplifier, control logic and a high speed serial interface, all in an 8-pin DIP. The V_{DD} input is used as the reference for the part so no external reference is needed. This offers considerable space saving over alternative solutions.
2. Low Power, Single Supply Operation
   The AD7896 operates from a single +3 V supply and consumes only 10 mW typical. The automatic power down mode, where the part goes into power down once conversion is complete and "wakes up" before the next conversion cycle, makes the AD7896 ideal for battery powered or portable applications.
3. High Speed Serial Interface
   The part provides high speed serial data and serial clock lines allowing for an easy, two-wire serial interface arrangement.

AD7896–SPECIFICATIONS (V_{DD} = +3.0 V to +3.6 V, AGND = DGND = 0 V. All specifications T_{MIN} to T_{MAX} unless otherwise noted)

NOTES

[1]Temperature ranges are as follows: A, B Versions: –40°C to +85°C; S Version: –55°C to +125°C.

[2]Applies to Mode 1 operation. See section on operating modes.

[3]See Terminology.

[4]Sample tested @ +25°C to ensure compliance.

[5]This 13 µs includes the "wake-up" time from standby. This "wake-up" time is timed from the rising edge of $\overline{\text{CONVST}}$, whereas conversion is timed from the falling edge of $\overline{\text{CONVST}}$, for narrow $\overline{\text{CONVST}}$ pulse width the conversion time is effectively the "wake-up" time plus conversion time hence 13 µs. This can be seen from Figure 3. Note that if the $\overline{\text{CONVST}}$ pulse width is greater than 5 µs then the effective conversion time will increase beyond 13 µs.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1] (V_{DD} = +3.0 V to +3.6 V, AGND = DGND = 0 V)

Parameter	A, B Versions	S Version	Units	Test Conditions/Comments
t_1	50	50	ns min	$\overline{\text{CONVST}}$ Pulse Width
t_2	50	50	ns min	SCLK High Pulse Width
t_3	50	50	ns min	SCLK Low Pulse Width
t_4	80[2]	80[2]	ns max	Data Access Time After Falling Edge of SCLK
t_5	15	15	ns min	Data Hold Time After Falling Edge of SCLK
t_6	100[3]	100[3]	ns max	Bus Relinquish Time After Falling Edge of SCLK

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are measured with tr = tf = 1 ns (10% to 90% of +3.3 V) and timed from a voltage level of +1.6 V.
[2]Measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.0 V.
[3]Derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the time, t_6, quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

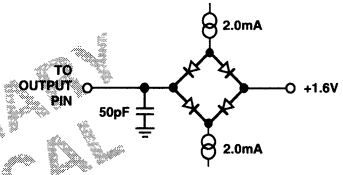

Figure 1. Load Circuit for Access Time and Bus Relinquish Time

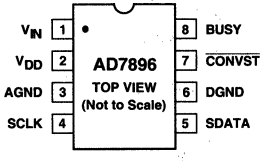
CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7896 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN FUNCTION DESCRIPTION

Pin No.	Pin Mnemonic	Description
1	V_{IN}	Analog Input. The analog input range is 0 V to V_{DD}.
2	V_{DD}	Positive supply voltage, +3.0 V to 3.6 V.
3	AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
4	SCLK	Serial Clock Input. An external serial clock is applied to this input to obtain serial data from the AD7896. A new serial data bit is clocked out on the falling edge of this serial clock. Data is guaranteed valid for 15 ns after this falling edge so the µP can accept data on the either the falling edge or the rising edge. The serial clock input should be taken low at the end of the serial data transmission.
5	SDATA	Serial Data Output. Serial data from the AD7896 is provided at this output. The serial data is clocked out by the falling edge of SCLK, but the data can also be read on the falling edge of the SCLK. This is possible because data bit N is valid for a specified time after the falling edge of the SCLK (data hold time) and can be read before data bit N+1 becomes valid a specified time after the falling edge of SCLK (data access time) (see Figure 4). Sixteen bits of serial data are provided with four leading zeros followed by the 12-bits of conversion data. On the sixteenth falling edge of SCLK, the SDATA line is held for the data hold time and then disabled (three-stated). Output data coding is straight binary.
6	DGND	Digital Ground. Ground reference for digital circuitry.
7	$\overline{\text{CONVST}}$	Convert Start. Edge-triggered logic input. On the falling edge of this input, the track/hold goes into its hold mode and conversion is initiated. If $\overline{\text{CONVST}}$ is low at the end of conversion, the part goes into power down mode. In this case, the rising edge of $\overline{\text{CONVST}}$ "wakes up" the part.
8	BUSY	The BUSY pin is used to indicate when the part is doing a conversion. The BUSY pin will go high on the falling edge of $\overline{\text{CONVST}}$ and will return low when the conversion is complete.

PIN CONFIGURATION



ORDERING GUIDE

Model	Temperature Range	Linearity Error (LSB)	SNR (dB)	Package Option*
AD7896AN	–40°C to +85°C	±1 LSB	70 dB	N-8
AD7896BN	–40°C to +85°C	±1/2 LSB	72 dB	N-8

*N = Plastic DIP; Q = Cerdip; R = SOIC. For outline information see Package Information section.

TERMINOLOGY

Relative Accuracy

This is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints of the transfer function are zero scale (*which is V_{IN} = AGND + 1/2 LSB*) a point 1/2 LSB below the first code transition (00 . . . 000 to 00 . . . 001) and full scale (*which is V_{IN} = AGND + V_{DD} – 1/2 LSB*), a point 1/2 LSB above the last code transition (11 . . . 110 to 11 . . . 111).

Differential Nonlinearity

This is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Unipolar Offset Error

This is the deviation of the first code transition (00 . . . 000 to 00 . . . 001) from the ideal V_{IN} voltage (AGND + 1 LSB).

Positive Full-Scale Error

This is the deviation of the last code transition (11 . . . 110 to 11 . . . 111 from the ideal (V_{IN} = AGND + V_{DD} – 1 LSB) after the offset error has been adjusted out.

Track/Hold Acquisition Time

Track/hold acquisition time is the time required for the output of the track/hold amplifier to reach its final value, within ±1/2 LSB, after the end of conversion (*the point at which the track/hold returns into track mode*). It also applies to a situation where there is a step input change on the input voltage applied to the selected V_{IN} input of the AD7896. It means that the user must wait for the duration of the track/hold acquisition time after the end of conversion or after a step input change to V_{IN} before starting another conversion, to ensure the part operates to specification.

Signal to (Noise + Distortion) Ratio

This is the measured ratio of signal to (noise + distortion) at the output of the A/D converter. The signal is the rms amplitude of the fundamental. Noise is the sum of all nonfundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio is dependent on the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to (noise + distortion) ratio for an ideal N-bit converter with a sine wave input is given by:

$$Signal\ to\ (Noise + Distortion) = (6.02N + 1.76)\ dB$$

Thus for a 12-bit converter, this is 74 dB.

Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the rms sum of harmonics to the fundamental. For the AD7896, it is defined as:

$$THD\ (dB) = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonics.

Peak Harmonic or Spurious Noise

Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor, it will be a noise peak.

Intermodulation Distortion

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation distortion terms are those for which neither m nor n are equal to zero. For example, the second order terms include (fa + fb) and (fa – fb), while the third order terms include (2fa + fb), (2fa – fb), (fa + 2fb) and (fa – 2fb).

The AD7896 is tested using the CCIF standard where two input frequencies near the top end of the input bandwidth are used. In this case, the second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

OPERATING MODES

Mode 1 Operation (High Sampling Performance)

The timing diagram in Figure 2 is for optimum performance in Operating Mode 1 where the falling edge of $\overline{\text{CONVST}}$ starts conversion and puts the Track/Hold amplifier into its hold mode. This falling edge of $\overline{\text{CONVST}}$ also causes the BUSY signal to go high to indicate that a conversion is taking place. The BUSY signal goes low when the conversion is complete which is 8 µs max after the falling edge of $\overline{\text{CONVST}}$, and new data from this conversion is available in the output register of the AD7896. A read operation accesses this data. This read operation consists of 16 clock cycles, and the length of this read operation will depend on the serial clock frequency. For the fastest throughput rate (with a serial clock of 10 MHz) the read operation will take 1.6 µs. The read operation must be complete at least 400 ns before the falling edge of the next $\overline{\text{CONVST}}$, and this gives a total time of 10 µs for the full throughput time (equivalent to 100 kHz). This mode of operation should be used for high sampling applications.

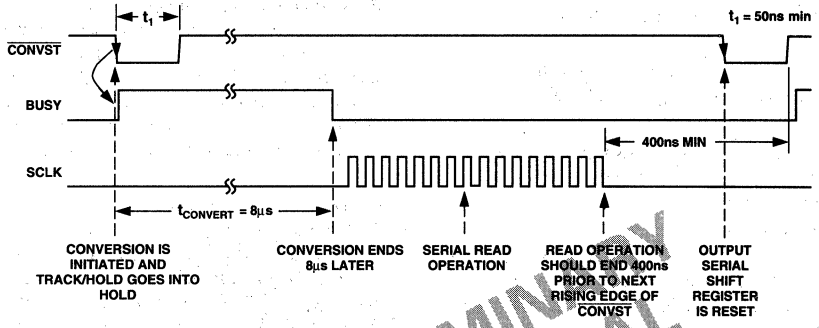

Figure 2. Mode 1 Timing Operation Diagram for High Sampling Performance

Mode 2 Operation (Auto Sleep After Conversion)

The timing diagram in Figure 3 is for optimum performance in Operating Mode 2 where the part automatically goes into sleep mode once BUSY goes low after conversion and "wakes up" before the next conversion takes place. This is achieved by keeping $\overline{\text{CONVST}}$ low at the end of conversion whereas it was high at the end of conversion for Mode 1 operation. The rising edge of $\overline{\text{CONVST}}$ "wakes up" the part. This wake-up time is 5 µs at which point the Track/Hold amplifier goes into its hold mode. The conversion takes 8 µs after this, provided the $\overline{\text{CONVST}}$ has gone low, giving a total of 13 µs from the rising edge of $\overline{\text{CONVST}}$ to the conversion being complete which is indicated by the BUSY going low. Note that since the wake-up time from the rising edge of $\overline{\text{CONVST}}$ is 5 µs, when the $\overline{\text{CONVST}}$ pulse width is greater than 5 µs the conversion will take more than the 13 µs shown in diagram from the rising edge of $\overline{\text{CONVST}}$. This is because the Track/Hold amplifier goes into its hold mode on the falling edge of $\overline{\text{CONVST}}$ and then the conversion will not be complete for a further 8 µs. In this case the BUSY will be the best indicator for when the conversion is complete. Even though the part is in sleep mode, data can still be read from the part. The read operation consists of 16 clock cycles as in Mode 1 operation. For the fastest serial clock of 10 MHz the read operation will take 1.6 µs, and this must be complete at least 400 ns before the falling edge of the next $\overline{\text{CONVST}}$ to allow the Track/Hold amplifier to have enough time to settle. This mode is very useful when the part is converting at a slow rate as the power consumption will be significantly reduced from that of Mode 1 operation.

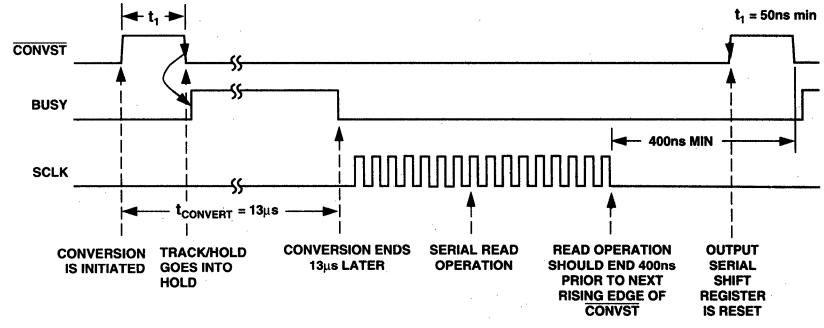

Figure 3. Mode 2 Timing Diagram Where Automatic Sleep Function Is Initiated

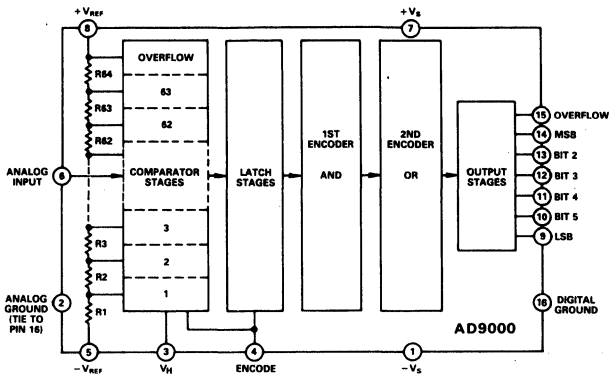
FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9000 is a 6-bit, high speed, analog-to-digital converter with ECL compatible outputs and a bipolar input stage. The AD9000 is fabricated in a high-performance bipolar process which allows encode rates up to 77MSPS.

The AD9000 employs the standard flash converter architecture based on 64 individual comparators which simultaneously determine the precise analog signal level. The comparators are followed by two stages of decoding logic, allowing the AD9000 to operate with a very low error rate. The low 35pF input capacitance of the AD9000 greatly simplifies the analog driver stage. Also incorporated into the AD9000 design is an overflow output bit as well as a hysteresis control pin to modify comparator sensitivity.

The AD9000 is offered as both an commercial temperature range device 0 to +70°C, and as an extended temperature range device −55°C to +125°C. Both versions are available packaged in a 16-pin ceramic DIP. The extended temperature range device is also available in a 28-pin ceramic LCC package. The extended temperature range versions are offered as fully compliant MIL-STD-883 Class B devices.

NOTES
[1] $A_{IN} = +V_{REF}$.
[2] Determined by 3dB reduction in reconstructed output at 75MSPS.
[3] Under normal operating conditions, the analog input voltages should not exceed nominal ±2V operating range, nor the supply voltages ($+V_S$ and $-V_S$), whichever is smaller.
[4] Under normal operating conditions the differential reference voltage may range from ±0.5V to ±2V; $+V_{REF} \geq -V_{REF}$.
[5] Output terminated with 100Ω resistors to −2.0V.
[6] Measured from the leading edge of ENCODE to data out on Bit 1 (MSB).
[7] Measured from the trailing edge of ENCODE to data out on Bit 1 (MSB).
[8] For full-scale step input, 6-bit accuracy is attained in specified time.
[9] Recovers to 6-bit accuracy in specified time, after 150% full-scale input overvoltage.
[10] Measured on Bit 1 (MSB) only.
[11] Measured at 50MSPS encode rate.
[12] Analog input frequency = 15MHz.
[13] RMS signal to RMS noise, with 540kHz analog input signal.
[14] Peak-to-peak signal to rms noise, with 540kHz analog input signal.
[15] $f_1 = 9.3$MHz; $f_2 = 7.6$MHz; Encode = 42MHz.
[16] DC to 8.2MHz noise bandwidth with 3.886MHz slot.
[17] Supply voltage should remain stable within ±5% for normal operation.

Specifications subject to change without notice.

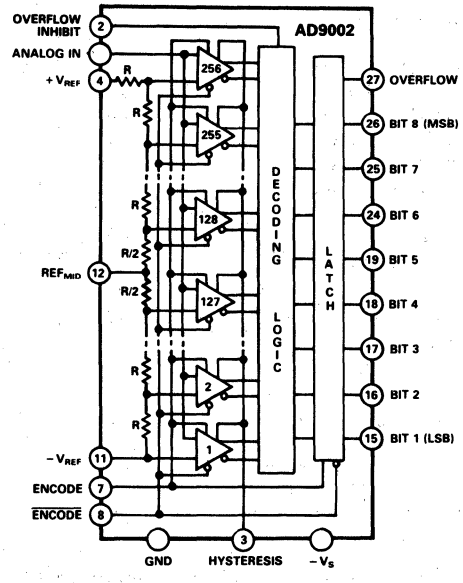
High Speed 8-Bit Monolithic A/D Converter

AD9002

FEATURES
150MSPS Encode Rate
Low Input Capacitance: 17pF
Low Power: 750mW
−5.2V Single Supply
MIL-STD-883 Compliant Versions Available

APPLICATIONS
Radar Systems
Digital Oscilloscopes/ATE Equipment
Laser/Radar Warning Receivers
Digital Radio
Electronic Warfare (ECM, ECCM, ESM)
Communication/Signal Intelligence

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9002 is an 8-bit, high speed, analog-to-digital converter. The AD9002 is fabricated in an advanced bipolar process which allows operation at sampling rates in excess of 150 megasamples/second. Functionally, the AD9002 is comprised of 256 parallel comparator stages whose outputs are decoded to drive the ECL compatible output latches.

An exceptionally wide large signal analog input bandwidth of 160MHz is due to an innovative comparator design and very close attention to device layout considerations. The wide input bandwidth of the AD9002 allows very accurate acquisition of high speed pulse inputs, without an external track-and-hold. The comparator output decoding scheme minimizes false codes which is critical to high speed linearity.

The AD9002 provides an external hysteresis control pin which can be used to optimize comparator sensitivity to further improve performance. Additionally, the AD9002's low power dissipation of 750mW makes it usable over the full extended temperature range. The AD9002 also incorporates an overflow bit to indicate overrange inputs. This overflow output can be disabled with the overflow inhibit pin.

The AD9002 is available in two grades, one with 0.5LSB linearity and one with 0.75LSB linearity. Both versions are offered in an industrial grade, −25°C to +85°C, packaged in a 28-pin DIP and a 28-pin JLCC. The military temperature range devices, −55°C to +125°C, are available in ceramic DIP and LCC packages and are compliant to MIL-STD-883 Class B.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods of time may affect device reliability.
[2]$+V_{REF} \geq -V_{REF}$ under all circumstances.
[3]Maximum junction temperature (t_J max) should not exceed 175°C for ceramic packages, and 150°C for plastic packages:

$t_J = PD\ (\theta_{JA}) + t_A$
$PD\ (\theta_{JC}) + t_C$

where
PD = power dissipation
θ_{JA} = thermal impedance from junction to ambient (°C/W)
θ_{JC} = thermal impedance from junction to case (°C/W)
t_A = ambient temperature (°C)
t_C = case temperature (°C)
typical thermal impedances are:
Ceramic DIP $\theta_{JA} = 56°C/W$; $\theta_{JC} = 20°C/W$
Plastic DIP $\theta_{JA} = 60°C/W$; $\theta_{JC} = 20°C/W$
Ceramic LCC $\theta_{JA} = 69°C/W$; $\theta_{JC} = 23°C/W$
PLCC $\theta_{JA} = 60°C/W$, $\theta_{JC} = 19°C/W$.
[4]Measured with AIN = 0V.
[5]Measured by FFT analysis where fundamental is −3dB FS.
[6]Input slew rate derived from rise time (10 to 90%) of full scale input.
[7]Outputs terminated through 100Ω to −2V.
[8]Measured from ENCODE in to data out for LSB only.
[9]For full-scale step input, 8-bit accuracy is attained in specified time.
[10]Recovers to 8-bit accuracy in specified time after 150% full-scale input overvoltage.
[11]Output time skew includes high-to-low and low-to-high transitions as well as bit-to-bit time skew differences.
[12]ENCODE signal rise/fall times should be less than 10ns for normal operation.
[13]Measured at 125MSPS encode rate.
[14]Analog input frequency = 1.23MHz.
[15]RMS signal to rms noise, with 1.23MHz analog input signal.
[16]Input signals 1V p-p @1.23MHz and 1V p-p @2.30MHz.
[17]Supplies should remain stable within ±5% for normal operation.
[18]Measured at −5.2V ±5%.

Specifications subject to change without notice.

Recommended Operating Conditions

	Input Voltage		
Parameter	**Min**	**Nominal**	**Max**
$-V_S$	−5.46	−5.20	−4.94
$+V_{REF}$	$-V_{REF}$	0.0V	+0.1
$-V_{REF}$	−2.1	−2.0	$+V_{REF}$
Analog Input	$-V_{REF}$		$+V_{REF}$

EXPLANATION OF TEST LEVELS

Test Level I	–	100% production tested.
Test Level II	–	100% production tested at +25°C, and sample tested at specified temperatures.
Test Level III	–	Sample tested only.
Test Level IV	–	Parameter is guaranteed by design and characterization testing.
Test Level V	–	Parameter is a typical value only.
Test Level VI	–	All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

ORDERING GUIDE

Model	Linearity	Temperature Range	Package Option[1]
AD9002AD	0.75LSB	−25°C to +85°C	D-28
AD9002BD	0.50LSB	−25°C to +85°C	D-28

FUNCTIONAL DESCRIPTION

Pin #	Name	Description
1	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
2	OVERFLOW INH	OVERFLOW INHIBIT controls the data output polarity for overvoltage inputs.

ANALOG INPUT	OVERFLOW ENABLED (FLOATING OR −5.2V) OF	D_1	D_2	D_3	D_4	D_5	D_6	D_7	D_8	OVERFLOW INHIBITED (GND) OF	D_1	D_2	D_3	D_4	D_5	D_6	D_7	D_8
$V_{IN} > +V_{REF}$	1	0	0	0	0	0	0	0	0		0	1	1	1	1	1	1	1
$V_{IN} \leq +V_{REF}$	0	X	X	X	X	X	X	X	X		0	X	X	X	X	X	X	X	X

3	HYSTERESIS	The Hysteresis control voltage varies the comparator hysteresis from 0mV to 10mV, for a change from −5.2V to −2.2V at the Hysteresis control pin. Normally connected to −5.2V.
4	$+V_{REF}$	The most positive reference voltage for the internal resistor ladder.
5	ANALOG INPUT	One of two analog input pins. Both analog input pins should be connected together.
6	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
7	ENCODE	Noninverted input of the differential encode input. This pin is driven in conjunction with $\overline{\text{ENCODE}}$. Data is latched on the rising edge of the ENCODE signal.
8	$\overline{\text{ENCODE}}$	Inverted input of the differential encode input. This pin is driven in conjunction with ENCODE.
9	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
10	ANALOG INPUT	One of two analog input pins. Both analog inputs should be connected together.
11	$-V_{REF}$	The most negative reference voltage for the internal resistor ladder.
12	REF_{MID}	The midpoint tap on the internal resistor ladder.
13	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
14	DIGITAL $-V_S$	One of two negative digital supply pins (nominally −5.2V). Both digital supply pins should be connected together.
15	D1	Digital data output (LSB).
16-19	D2-D5	Digital data output.
20	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
21, 22	ANALOG $-V_S$	One of two negative analog supply pins (nominally −5.2V). Both analog supply pins should be connected together.
23	DIGITAL GROUND	One of four digital ground pins. All digital ground pins should be connected together.
24, 25	D6, D7	Digital data output.
26	D8	Digital data output (MSB).
27	OVERFLOW	Overflow data output. Logic high indicates an input overvoltage ($V_{IN} > +V_{REF}$) if OVERFLOW INHIBIT is enabled (overflow enabled, −5.2V). See OVERFLOW INHIBIT.
28	DIGITAL $-V_S$	One of two negative digital supply pins (nominally −5.2V). Both digital supply pins should be connected together.

NOTES

[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]$+V_{REF} \geq -V_{REF}$ under all circumstances.

[3]Maximum junction temperature (t_J max) should not exceed +175°C for ceramic packages, and +150°C for plastic packages:

$t_J = PD\ (\theta_{JA}) + t_A$

$PD\ (\theta_{JC}) + t_C$

where

PD = power dissipation

θ_{JA} = thermal impedance from junction to ambient (°C/W)

θ_{JC} = thermal impedance from junction to case (°C/W)

t_A = ambient temperature (°C)

t_C = case temperature (°C)

typical thermal impedances are:

Ceramic DIP $\theta_{JA} = 42°C/W$; $\theta_{JC} = 10°C/W$

Ceramic LCC $\theta_{JA} = 50°C/W$; $\theta_{JC} = 15°C/W$

JLCC $\theta_{JA} = 59°C/W$; $\theta_{JC} = 15°C/W$.

[4]Measured with Analog Input = 0V.

[5]Measured by FFT analysis where fundamental is −3dBc.

[6]Input slew rate derived from rise time (10% to 90%) of full-scale step input.

[7]Outputs terminated with two equivalent 'LS00 type loads. (See load circuit.)

[8]Measured from ENCODE into data out for LSB only.

[9]For full-scale step input, 8-bit accuracy is attained in specified time.

[10]Recovers to 8-bit accuracy in specified time, after 150% full-scale input overvoltage.

[11]Output time skew includes high-to-low and low-to-high transitions as well as bit-to-bit time skew differences.

[12]ENCODE signal rise/fall times should be less than 30ns for normal operation.

[13]Measured at 75MSPS encode rate. Harmonic data based on worst case harmonics.

[14]Analog input frequency = 1.23MHz.

[15]RMS signal to rms noise, including harmonics with 1.23MHz analog input signal.

[16]NPR measured @ 0.5MHz. Noise Source is 250mW (rms) from 0.5MHz to 8MHz.

[17]Supplies should remain stable within ±5% for normal operation.

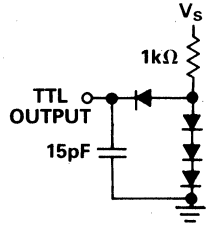
[18]Measured at −5.2V ±5% and +5.0V ±5%.

Specifications subject to change without notice.

Recommended Operating Conditions

Parameter	Input Voltage		
	Min	Nominal	Max
$-V_S$	−5.46	−5.20	−4.94
$+V_S$	+4.75	5.00	+5.25
$+V_{REF}$	$-V_{REF}$	0.0V	+0.1
$-V_{REF}$	−2.1	−2.0	$+V_{REF}$
Analog Input	$-V_{REF}$		$+V_{REF}$

LOAD CIRCUIT



EXPLANATION OF TEST LEVELS

Test Level I – 100% production tested.

Test Level II – 100% production tested at +25°C, and sample tested at specified temperatures.

Test Level III – Sample tested only.

Test Level IV – Parameter is guaranteed by design and characterization testing.

Test Level V – Parameter is a typical value only.

Test Level VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

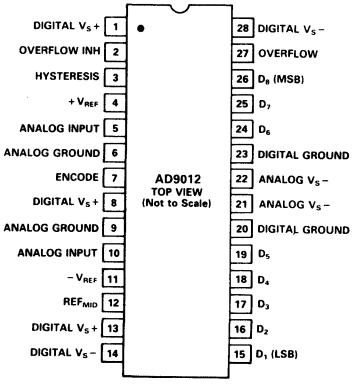
FUNCTIONAL DESCRIPTION

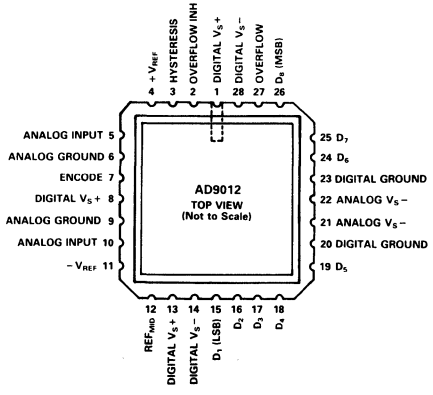
Pin #	Name	Description
1	DIGITAL $+V_S$	One of three positive digital supply pins (nominally $+5.0V$).
2	OVERFLOW INH	OVERFLOW INHIBIT controls the data output coding for overvoltage inputs ($AIN \geq +V_{REF}$).

ANALOG INPUT	OVERFLOW ENABLED (FLOATING OF D_1 D_2 D_3 D_4 D_5 D_6 D_7 D_8	OVERFLOW INHIBITED (GND) OF D_1 D_2 D_3 D_4 D_5 D_6 D_7 D_8
$V_{IN} \geq +V_{REF}$	1 0 0 0 0 0 0 0 0	0 1 1 1 1 1 1 1 1
$V_{IN} < +V_{REF}$	0 X X X X X X X X	0 X X X X X X X X

3	HYSTERESIS	The Hysteresis control voltage varies the comparator hysteresis from 0mV to 10mV, for a change from $-5.2V$ to $-2.2V$ at the Hysteresis control pin.
4	$+V_{REF}$	The most positive reference voltage for the internal resistor ladder.
5	ANALOG INPUT	One of two analog input pins. Both analog input pins should be connected together.
6	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
7	ENCODE	TTL level encode command input. ENCODE is rising edge sensitive.
8	DIGITAL $+V_S$	One of three positive digital supply pins (nominally $+5.0V$).
9	ANALOG GROUND	One of two analog ground pins. Both analog ground pins should be connected together.
10	ANALOG INPUT	One of two analog input pins. Both analog inputs should be connected together.
11	$-V_{REF}$	The most negative reference voltage for the internal resistor ladder.
12	REF_{MID}	The midpoint tap on the internal resistor ladder.
13	DIGITAL $+V_S$	One of three positive digital supply pins (nominally $+5.0V$)
14	DIGITAL $-V_S$	One of two negative digital supply pins (nominally $-5.2V$). Both digital supply pins should be connected together.
15	D_1 (LSB)	Digital data output. D_1 (LSB) is the least significant bit of the digital output word.
16-19	D_2-D_5	Digital data output.
20	DIGITAL GROUND	One of two digital ground pins. Both digital grounds pins should be connected together.
21, 22	ANALOG $-V_S$	One of two negative analog supply pins (nominally $-5.2V$). Both analog supply pins should be connected together.
23	DIGITAL GROUND	One of two digital ground pins. Both digital ground pins should be connected together.
24, 25	D_6, D_7	Digital data output.
26	D_8 (MSB)	Digital data output D_8 (MSB) is the most significant bit of the digital output word.
27	OVERFLOW	Overflow data output. Logic HIGH indicates an input overvoltage ($V_{IN} > +V_{REF}$), if OVERFLOW INHIBIT is enabled (overflow enabled, floating). See OVERFLOW INHIBIT.
28	DIGITAL $-V_S$	One of two negative digital supply pins (nominally $-5.2V$). Both digital supply pins should be connected together.

PIN DESIGNATIONS





10-Bit 60 MSPS A/D Converter

AD9020

FEATURES
Monolithic 10-Bit/60 MSPS Converter
TTL Outputs
Bipolar (±1.75 V) Analog Input
56 dB SNR @ 2.3 MHz Input
Low (45 pF) Input Capacitance
MIL-STD-883 Compliant Versions Available

APPLICATIONS
Digital Oscilloscopes
Medical Imaging
Professional Video
Radar Warning/Guidance Systems
Infrared Systems

GENERAL DESCRIPTION

The AD9020 A/D converter is a 10-bit monolithic converter capable of word rates of 60 MSPS and above. Innovative architecture using 512 input comparators instead of the traditional 1024 required by other flash converters reduces input capacitance and improves linearity.

Encode and outputs are TTL-compatible, making the AD9020 an ideal candidate for use in low power systems. An overflow bit is provided to indicate analog input signals greater than $+V_{SENSE}$.

Voltage sense lines are provided to insure accurate driving of the $\pm V_{REF}$ voltages applied to the units. Quarter-point taps on the resistor ladder help optimize the integral linearity of the unit.

Either 68-pin ceramic leaded (gull wing) packages or ceramic LCCs are available and are specifically designed for low thermal impedances. Two performance grades for temperatures of both 0 to +70°C and −55°C to +125°C ranges are offered to allow the user to select the linearity best suited for each application. Dynamic performance is fully characterized and production tested at +25°C. MIL-STD-883 units are available.

The AD9020 A/D Converter is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD9020/883B data sheet for detailed specifications.

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]Typical thermal impedances (part soldered onto board): 68-pin leaded ceramic chip carrier: θ_{JC} = 1°C/W; θ_{JA} = 17°C/W (no air flow); θ_{JA} = 15°C/W (air flow = 500 LFM). 68-pin ceramic LCC: θ_{JC} = 2.6°C/W; θ_{JA} = 15°C/W (no air flow); θ_{JA} = 13°C/W (air flow = 500 LFM).

[3]$3/4_{REF}$, $1/2_{REF}$, and $1/4_{REF}$ reference ladder taps are driven from dc sources at +0.875 V, 0 V, and −0.875 V, respectively. Accuracy of the overflow comparator is not tested and not included in linearity specifications.

[4]Measured with ANALOG IN = $+V_{SENSE}$.

[5]Output delay measured as worst-case time from 50% point of the rising edge of ENCODE to 50% point of the slowest rising or falling edge of D_0–D_9. Output skew measured as worst-case difference in output delay among D_0–D_9.

[6]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.

[7]Intermodulation measured with analog input frequencies of 2.3 MHz and 3.0 MHz at 7 dB below full scale.

[8]Measured as the ratio of the worst-case change in transition voltage of a single comparator for a 5% change in $+V_S$ or $-V_S$.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.

II – 100% production tested at +25°C, and sample tested at specified temperatures.

III – Sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

AD9020 Pin Designations

AD9020 PIN DESCRIPTIONS

Pin No.	Name	Function
1	$1/2_{REF}$	Midpoint of internal reference ladder.
2, 16, 28, 29, 35, 41, 42, 54, 64	$-V_S$	Negative supply voltage; nominally −5.0 V ±5%.
3, 6, 15, 18, 25, 30, 33, 34, 37, 40, 45, 52, 55, 65, 68	$+V_S$	Positive supply voltage; nominally +5 V ±5%.
4, 5, 13, 17, 27, 31, 32 36, 38, 39, 43, 53, 66, 67	GROUND	All ground pins should be connected together and to low-impedance ground plane.
7	$3/4_{REF}$	Three-quarter point of internal reference ladder.
8, 9	ANALOG IN	Analog input; nominally between ±1.75 V.
11	$+V_{SENSE}$	Voltage sense line to most positive point on internal resistor ladder. Normally +1.75 V.
12	$+V_{REF}$	Voltage force connection for top of internal reference ladder. Normally driven to provide +1.75 V at $+V_{SENSE}$.
14	ENCODE	TTL-compatible convert command used to begin digitizing process.
19–23, 46–50	D_0–D_9	TTL-compatible digital output data.
51	OVERFLOW	TTL-compatible output indicating ANALOG IN > $+V_{SENSE}$.
56	$-V_{REF}$	Voltage force connection for bottom of internal reference ladder. Normally driven to provide −1.75 V at $-V_{SENSE}$.
57	$-V_{SENSE}$	Voltage sense line to most negative point on internal resistor ladder. Normally −1.75 V.
59	LSBs INVERT	Normally grounded. When connected to $+V_S$, lower order bits (D_0–D_8) are inverted.
61	MSB INVERT	Normally grounded. When connected to $+V_S$, most significant bit (MSB; D_9) is inverted.
63	$1/4_{REF}$	One-quarter point of internal reference ladder.

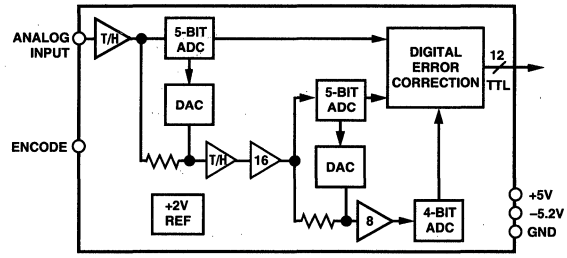
On-Chip T/H and Reference
High-Spurii Free Dynamic Range
TTL Logic

APPLICATIONS
Radar Receivers
Digital Communications
Digital Instrumentation
Electro-Optics

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD9022 is a high speed, high performance, monolithic 12-bit analog-to-digital converter. All necessary functions, including track-and-hold (T/H) and reference, are included on chip to provide a complete conversion solution. It is a companion unit to the AD9023; the primary difference between the two is that all logic for the AD9022 is TTL compatible, while the AD9023 utilizes ECL logic for digital inputs and outputs. Pinouts for the two parts are nearly identical.

Operating from +5 V and –5.2 V supplies, the AD9022 provides excellent dynamic performance. Sampling at 20 Msps with A_{IN} = 1 MHz, the spurious free dynamic range (SFDR) is typically 80 dB; with A_{IN} = 9.6 MHz, SFDR is 74 dB. SNR is typically 65 dB.

The on-board T/H has a 100 MHz bandwidth and, more importantly, is designed to provide excellent dynamic performance for analog input frequencies above Nyquist. This feature is necessary in many under-sampling signal processing applications, such as in direct IF to digital conversion.

To maintain dynamic performance at higher IFs, monolithic RF track-and-holds (such as the AD9100 and AD9101 Samplifier™) can be used with the AD9022 to process signals up to and beyond 70 MHz.

Samplifier is a trademark of Analog Devices, Inc.

With DNL typically less than 0.5 LSB and 20 ns transient response settling time, the AD9022 provides excellent results when low-frequency analog inputs must be oversampled (such as CCD digitization). The full scale analog input is ±1 V with a 300 Ω input impedance. The analog input can be driven directly from the signal source, or can be buffered by the AD96xx series of low noise, low distortion buffer amplifiers.

All timing is internal to the AD9022; the clock signal initiates the conversion cycle. For best results, the encode command should contain as little jitter as possible. High speed layout practices must be followed to ensure optimum A/D performance.

The AD9022 is built on a trench isolated bipolar process and utilizes an innovative multipass architecture (see the block diagram). The unit is packaged in 28-pin ceramic DIPs and gullwing surface mount packages. The AD9022 is specified to operate over the industrial (–25°C to +85°C) and military (–55°C to +125°C) temperature ranges.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

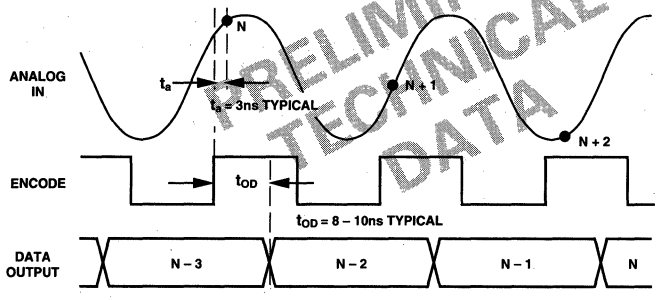
NOTES
[1]AD9022 load is a single LS latch.
[2]RMS signal-to-rms noise with analog input signal 1 dB below full scale at specified frequency.
[3]Intermodulation measured with analog input frequencies of 9.3 MHz and 9.6 MHz at 7 dB below full scale.
[4]PSRR is sensitivity of offset error to power supply variations within the 5% limits shown.
Specifications subject to change without notice.



AD9022 Timing Diagram

ABSOLUTE MAXIMUM RATINGS[1]

$+V_S$ ..... +6 V
$-V_S$ ..... –6 V
Analog Input ..... $-V_S$ to $+V_S$
Digital Inputs ..... $-V_S$ to 0 V
Digital Output Current ..... 20 mA
Gain Adjust ..... $-V_S$ to $+V_S$
Offset Adjust ..... $-V_S$ to $+V_S$
Operating Temperature Range (Case)
AD9022AQ/AZ/BQ/BZ ..... –25°C to +85°C
AD9022SQ/SZ ..... –55°C to +125°C
Maximum Junction Temperature[2] ..... +175°C
Lead Temperature (Soldering, 10 sec) ..... +300°C
Storage Temperature Range ..... –65°C to +150°C

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Typical thermal impedances: "Q" Package (Ceramic DIP): θ_{JC} = 10°C/W; θ_{JA} = 35°C/W. "Z" Package (Gullwing Surface Mount): θ_{JC} = 13°C/W; θ_{JA} = 45°C/W.

ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option
AD9022AQ/BQ	–25°C to +85°C	28-Pin Ceramic DIP	Q-28
AD9022AZ/BZ	–25°C to +85°C	28-Pin Ceramic Leaded Chip Carrier	Z-28
AD9022SQ	–55°C to +125°C	28-Pin Ceramic DIP	Q-28
AD9022SZ	–55°C to +125°C	28-Pin Ceramic Leaded Chip Carrier	Z-28

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.

II – 100% production tested at +25°C, and sample tested at specified temperatures. AC testing done on sample basis.

III – Sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; guaranteed by design and characterization testing for industrial devices.

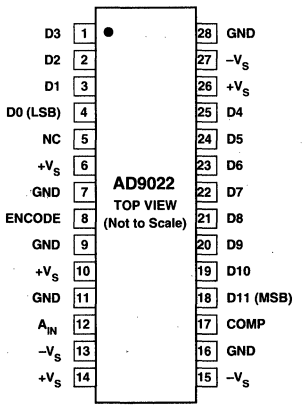
DIE LAYOUT AND MECHANICAL INFORMATION

Die Dimensions ..... 205 × 228 × 21 (±1) mils
Pad Dimensions ..... 4 × 4 mils
Metalization ..... Aluminum
Backing ..... None
Substrate Potential ..... $-V_S$
Transistor Count 4,080
Passivation ..... Oxynitride
Die Attach ..... Silver Glass
Bond Wire ..... Aluminum

PIN DESCRIPTIONS

Pin No.	Name	Function
1–3	D3–D1	Digital output bits of ADC; TTL/CMOS compatible.
4	D0 (LSB)	Least significant bit of ADC output; TTL/CMOS compatible.
5	NC	No Connection Internally
6	$+V_S$	+5 V Power Supply
7	GND	Ground
8	ENCODE	Encode clock input to ADC. Internal T/H is placed in hold mode (ADC is encoding) on rising edge of encode signal.
9	GND	Ground
10	$+V_S$	+5 V Power Supply
11	GND	Ground
12	A_{IN}	Noninverting input to T/H amplifier.
13	$-V_S$	–5.2 V Power Supply
14	$+V_S$	+5 V Power Supply
15	$-V_S$	–5.2 V Power Supply
16	GND	Ground
17	COMP	Should be connected to $-V_S$ through 0.1 μF capacitor.
18	D11 (MSB)	Most significant bit of ADC output; TTL/CMOS compatible.
19–25	D10–D4	Digital output bits of ADC; TTL/CMOS compatible.
26	$+V_S$	+5 V Power Supply
27	$-V_S$	–5.2 V Power Supply
28	GND	Ground

PIN DESIGNATIONS



NC = NO CONNECT
COMPENSATION (PIN 17) SHOULD BE CONNECTED TO $-V_S$ THROUGH 0.01μF

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

DEFINITIONS OF SPECIFICATIONS

Analog Bandwidth
The analog input frequency at which the spectral power of the fundamental frequency (as determined by FFT analysis) is reduced by 3 dB.

Aperture Delay
The delay between the rising edge of the ENCODE command and the instant at which the analog input is sampled.

Aperture Uncertainty (Jitter)
The sample-to-sample variation in aperture delay.

Differential Nonlinearity
The deviation of any code from an ideal 1 LSB step.

Harmonic Distortion
The rms value of the fundamental divided by the rms value of the worst harmonic component.

Integral Nonlinearity
The deviation of the transfer function from a reference line measured in fractions of 1 LSB using a "best straight line" determined by a least square curve fit.

Minimum Conversion Rate
The encode rate at which the SNR of the lowest analog signal frequency tested drops by no more than 3 dB below the guaranteed limit.

Maximum Conversion Rate
The encode rate at which parametric testing is performed.

Output Propagation Delay
The delay between the 50% point of the rising edge of the ENCODE command and the time when all output data bits are within valid logic levels.

Overvoltage Recovery Time
The amount of time required for the converter to recover to 12-bit accuracy after an analog input signal 150% of full scale is reduced to the full-scale range of the converter.

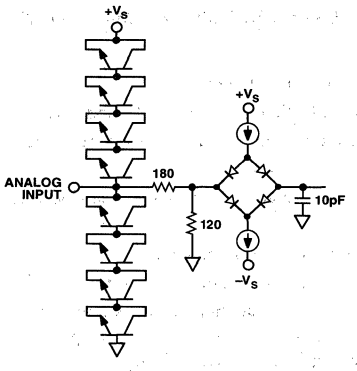
Power Supply Rejection Ratio (PSRR)
The ratio of a change in input offset voltage to a change in power supply voltage.

Signal-to-Noise Ratio (SNR)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, including harmonics but excluding dc, with an analog input signal 1 dB below full scale.

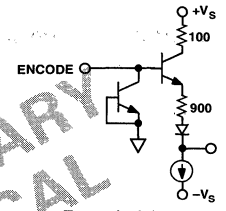
Signal-to-Noise Ratio (Without Harmonics)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, excluding the first five harmonics and dc, with an analog input signal 1 dB below full scale.

Transient Response
The time required for the converter to achieve 12-bit accuracy when a step function is applied to the analog input.

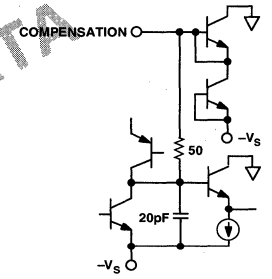
Two-Tone Intermodulation Distortion (IMD) Rejection
The ratio of the power of either of two input signals to the power of the strongest third-order IMD signal.



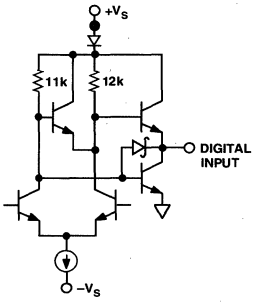
Analog Input



Encode Input



Compensation



Output Stage

Figure 1. Equivalent Circuits

THEORY OF OPERATION

Refer to the block diagram.

The AD9022 employs a three pass subranging architecture and digital error correction. This combination of design techniques ensures 12-bit accuracy at relatively low power.

Analog input signals are immediately attenuated through a resistor divider and applied directly to the sampling bridge of the track-and-hold (T/H). The T/H holds whatever analog value is present when the unit is strobed with an ENCODE command. The conversion process begins on the rising edge of this pulse, which should conform to the minimum and maximum pulse width requirements shown in the specifications. Operation below the recommended encode rate (2 Msps) may result in excessive droop in the internal T/H devices–leading to large dc and ac errors.

The held analog value of the first track-and-hold is applied to a 5-bit flash converter and a second T/H. The 5-bit flash converter resolves the most significant bits (MSBs) of the held analog voltage. These 5 bits are reconstructed via a 5-bit DAC and subtracted from the original T/H output signal to form a residue signal.

A second T/H holds the amplified residue signal while it is encoded with a second 5-bit flash ADC. Again the 5 bits are reconstructed and subtracted from the second T/H output to form a residue signal. This residue is amplified and encoded with a 4-bit flash ADC to provide the 3 least significant bits (LSBs) of the digital output and one bit of error correction.

Digital Error Correction logic aligns the data from the three flash converters and presents the result as a 12-bit parallel digital word. The output stage of the AD9022 is TTL. Output data may be strobed on the rising edge of the ENCODE command.

AD9022 IN RECEIVER APPLICATIONS

Advances in semiconductor processes have resulted in low cost digital signal processing (DSP) and analog signal processing which can help create cost effective alternative receiver designs. Today, an all-digital receiver allows tuning, demodulation, and detection of receiver signals in the digital domain. By digitizing IF signals directly and utilizing digital techniques, it becomes possible to make significant improvements in receiver design. For high frequency IFs, the ADC is the key to the receiver's performance. Unfortunately, the specifications frequently used by receiver designers and analog-to-digital (ADC) manufacturers are often very different. Noise Figure and Intercept Point are common measures of noise and linearity in analog RF system design. ADCs are more frequently specified in terms of SNR and harmonic distortion.

Noise

Noise figure (NF) is a measure of receiver sensitivity and is defined as the degradation of signal-to-noise ratio (SNR) as a signal passes through a device. In equation form:

$$NF = SNR\ (in) - SNR\ (out)$$

Noise figure is a bandwidth invariant parameter for reasonably narrow bandwidths in most devices. The system noise figure for a combination of amplifiers and mixers, for instance, can be analyzed without regard to the information bandwidth.

Thermal noise contribution from the ADC behaves in a similar fashion; however, the spectral density of quantization noise is a function of the sample rate. In addition, the spectral density of the quantization noise is flat only in an ADC with perfect linearity, i.e., perfect 1 LSB step sizes.

To analyze the system noise performance, ADC noise figure is calculated by normalizing the SNR of the ADC output to a 1 Hz bandwidth. This result is given by:

$$SNR\ (/Hz) = SNR + 10\ log_{10}\ (Fs/2)$$

where Fs is the sample rate.

This will be true only for converters in which perfect quantization noise dominates. There may be an upper sample rate, above which the thermal noise of the converter is the dominant source of noise. In this case, normalization would be based on the noise bandwidth of the ADC. For an AD9022 with a typical SNR of 64 dB and a sample rate of 20 Msps, the normalized SNR is equal to 134 dB (64 + 70). Both thermal and quantization noise contribute to this number.

The SNR of the input is assumed to be limited by the thermal noise of the input resistance, or –174 dBm/Hz. The input signal level is +10 dBm (2 V p-p into 50 Ω). Noise figure of the ADC can be calculated by:

$$NF = SNR\ (in) - SNR\ (out) = [+10 - (174)] - 134 = 50\ dB$$

Most ADCs detect input voltage levels, not power. Consequently, the input SNR can be determined more accurately by determining the ratio of the signal voltage to the noise voltage of the terminating resistor. However, both the input signal and noise voltage delivered to the ADC are also a function of the source impedance. The dependence of NF on sample rate, linearity, source and terminating impedances, and the number of assumptions that are required highlight the weakness of using NF as a figure of merit for an ADC. The rather large number that results bolsters this belief by indicating the ADC is often the weakest link in the signal processing path.

Linearity

The Third Order intercept point for a linear device (with some nonlinearity) is a good way to predict 3rd order spurious signals as a function of input signal level. For an ADC, however, this in an invalid concept except with signals near full scale. As the input signal is reduced, the performance burden shifts from the input track-and-hold (T/H) to the encoder. This creates a nonlinear function, as contrasted with the third order intercept behavior, which predicts an improvement in dynamic range as the signal level is decreased.

For signals near full scale, the intercept point is calculated the same as any device:

$$Intercept\ Point = [Harmonic\ Suppression/(N-1)] + Input\ Power$$

where N = the order of the IMD (3 in this case)

$$AD9022\ Intercept\ Point = 80/2 + 3\ dBm\ (7\ dBm\ below\ full\ scale) = 43\ dBm$$

For signals below this level, the spurious free dynamic range (SFDR) curves shown in the data sheet are a more accurate predictor of dynamic range. The SFDR curve is generated by measuring the ratio of the signal (either tone in the two-tone measurement) to the worst spurious signal which is observed as the analog input signal amplitude is swept.

The worst spurious signal is usually the second harmonic or 3rd order IMD. Actual results are shown on several plots. The straightline with a slope of one is constructed at the point where the worst SFDR touches the line. This line, extrapolated to full scale, gives the SFDR of the ADC. This value can then be used to predict the dynamic range by simply subtracting the input level from the SFDR. As shown on the two-tone SFDR plot, for example, a signal 20 dB below full scale will always have a dynamic range of at least 67 dB (87 dB – 20 dB).

It should be noted that all SFDR lines are constructed to be valid only below a certain level below full scale. Above these points, the linearity of the device is dominated by the nonlinearities of the front end and best predicted by the intercept point.

AD9022 NOISE PERFORMANCE

High speed, wide bandwidth ADCs such as the AD9022 are optimized for dynamic performance over a wide range of analog input frequencies. However, there are many applications (Imaging, Instrumentation, etc.) where dc precision is also important. Due to the wide input bandwidth of the AD9022 for a given input voltage, there will be a range of output codes which may occur. This is caused by unavoidable circuit noise within the wideband circuits in the ADC. If a dc signal is applied to the ADC and several thousand outputs are recorded, a distribution of codes such as that shown in the histogram below may result.

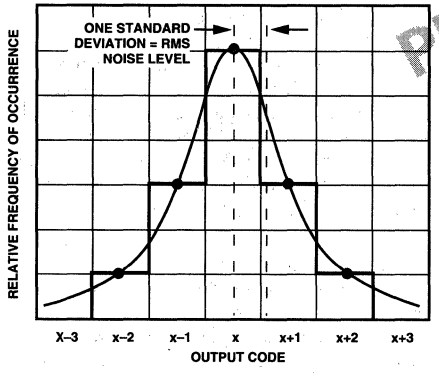


Figure 2. ADC Equivalent Input Noise

The correct code appears most of the time, but adjacent codes also appear with reduced probability. If a normal probability density curve is fitted to this Gaussian distribution of codes, the standard deviation will be equal to the equivalent input rms noise of the ADC. The rms noise may also be approximated by converting the SNR, as measured by a low frequency FFT, to an equivalent input noise. This method is accurate only if the SNR performance is dominated by random thermal noise (the low frequency SNR without harmonics is the best measure). Sixty-three dB equates to 1 LSB rms for a 2 V p-p (0.707 V rms) input signal. The AD9022 has approximately 0.5 LSB of rms noise or a noise limited SNR of 69 dB, indicating that noise alone does not limit the SNR performance of the device (quantization noise and linearity are also major contributors).

This thermal noise may come from several sources. The drive source impedance should be kept low to minimize resistor thermal noise. Some of the internal ADC noise is generated in the wideband T/H. Sampling ADCs generally have input bandwidths which exceed the Nyquist frequency of one-half the sampling rate. (The AD9022 has an input bandwidth of over 100 MHz, even though the sampling rate is limited to 20 Msps.)

Wide bandwidth is required to minimize gain and phase distortion and to permit adequate settling times in the internal amplifiers and T/Hs. But a certain amount of unavoidable noise is generated in the T/H and other wideband circuits within the ADC; this causes variation in output codes for dc inputs. Good layout, grounding, and decoupling techniques are essential to prevent external noise from coupling into the ADC and further corrupting performance.

USING THE AD9022

Layout Information

Preserving the accuracy and dynamic performance of the AD9022 requires that designers pay special attention to the layout of the printed circuit board.

Analog paths should be kept as short as possible and be properly terminated to avoid reflections. The analog input connection should be kept away from digital signals paths; this reduces the amount of digital switching noise which is capacitively coupled into the analog section. Digital signal paths should also be kept short, and run lengths should be matched to avoid propagation delay mismatch. The AD9022 digital outputs should be buffered or latched close to the device (<2 cm). This prevents load transients which may feed back into the device.

In high speed circuits, layout of the ground is critical. A single, low impedance ground plane on the component side of the board is recommended. Power supplies should be capacitively coupled to the ground plane with high quality 0.1 µF chip capacitors to reduce noise in the circuit. All power pins of the AD9022 should be bypassed individually. The compensation pin (COMP Pin 17) should be bypassed directly to the $-V_S$ supply (Pin 15) as close to the part as possible using a 0.1 µF chip capacitor.

Multilayer boards allow designers to lay out signal traces without interrupting the ground plane, and provide low impedance ground planes. In systems with dedicated analog and digital grounds, all grounds for the AD9022 should be connected to the analog ground plane.

In systems using multilayer boards, dedicated power planes are recommended to provide low impedance connections for device power. Sockets limit dynamic performance and are not recommended for use with the AD9022.

Timing

Conversion by the AD9022 is initiated by the rising edge of the ENCODE clock (Pin 8). All required timing is generated internal to the ADC. Care should be taken to ensure that the encode clock to the AD9022 is free from jitter that can degrade dynamic performance. The clock driver should be compatible with TTL LS logic series devices. Drivers with excessive slew rate or overdrive will degrade the dynamic performance of the AD9022.

Pulse width of the ADC encode clock must be controlled to ensure the best possible performance. Dynamic performance is guaranteed with a clock pulse HIGH minimum of 25 ns. Operation with narrower pulses will degrade SNR and dynamic performance. From a system perspective, this is generally not a problem, because a simple inverter can be used to generate a suitable clock if the system clock is less than 25 ns wide.

The AD9022 provides latched data outputs. Data outputs are available two pipeline delays and one propagation delay after the rising edge of the encode clock (refer to the AD9022 Timing Diagram). The length of the output data lines and the loads placed on them should be minimized to reduce transients within the AD9022; these transients can detract from the converter's dynamic performance.

Operation at encode rates less than 2 Msps is not recommended. The internal track-and-hold saturates, causing erroneous conversions. This T/H saturation precludes clocking the AD9022 in a burst mode.

The duty cycle of the encode clock for the AD9022 is critical for obtaining rated performance of the ADC. Internal pulse widths within the track-and-hold are established by the encode command pulse width; to ensure rated performance, minimum and maximum pulse width restrictions should be observed. Operation at 20 Msps is optimized when the duty cycle is held at 50%. Duty cycle variations of less than ±5% will cause no degradation in performance at 20 Msps.

Analog Input

The analog input (Pin 12) voltage range is nominally ±1.024 volts. The range is set with an internal voltage reference and cannot be adjusted by the user. The input resistance is 300 Ω and the analog bandwidth is 100 MHz, making the AD9022 useful in undersampling applications.

The AD9022 should be driven from a low impedance source. The noise and distortion of the amplifier should be considered to preserve the dynamic range of the AD9022.

Power Supplies

The power supplies of the AD9022 should be isolated from the supplies used for noisy devices (digital logic especially) to reduce the amount of noise coupled into the ADC. For optimum performance, linear supplies ensure that switching noise from the supplies does not introduce distortion products during the encoding process. If switching supplies must be used, decoupling recommendations above are critically important. The PSRR of the AD9022 as a function of the ripple frequency present on the supplies is shown in the performance graphs. Clearly, power supplies with the lowest possible frequency should be selected.

AD9022 EVALUATION BOARD

The evaluation board for the AD9022 (AD9022/PCB) provides an easy and flexible method for evaluating the ADC's performance without (or prior to) developing a user-specific printed circuit board. The two-sided board includes a reconstruction DAC and digital output interface; and uses the layout and applications suggestions outlined above. It is available from Analog Devices at nominal cost.

Generous space is provided near the analog input and digital outputs to support additional signal processing components the user may wish to add. This prototyping area includes through holes with 100 mil centers to support a variety of component additions.

Input/Output/Supply Information

Power supply, analog input, clock connections, and reconstructed output (RC OUTPUT) are identified by labels on the evaluation board.

Operation of the evaluation board will conform to the following characteristics:

Parameter	Typical	Units
Supply Current		
+5 V	150	mA
–5 V	300	mA
A_{IN}		
Impedance	51	Ω
Voltage Range	±1.024	V
CLOCK		
Impedance	51	Ω
Frequency	20	Msps
RC OUTPUT		
Impedance	51	Ω
Voltage Range	0 to –1	V

Analog Input

Analog input signals can be fed directly into the device under test input (A_{IN}). The A_{IN} input is terminated at the device with a 62 Ω resistor to give a parallel equivalent of 51 Ω (62 Ω‖300 Ω).

DAC Reconstruction

The AD9022 evaluation board provides an on-board AD9713B reconstruction DAC for observing the digitized analog input signal. The AD9713B is terminated into 51 Ω to provide a 1 V p-p signal at the output (RC Output).

Output Data

The output data bits are latched with two 74LS574 latches which drive a 40-pin connector (AMP p/n 102153-09). The data and clock signals are available at the connector per the pin assignments shown on the schematic of the evaluation board. Data is latched on the rising edge of the encode clock.

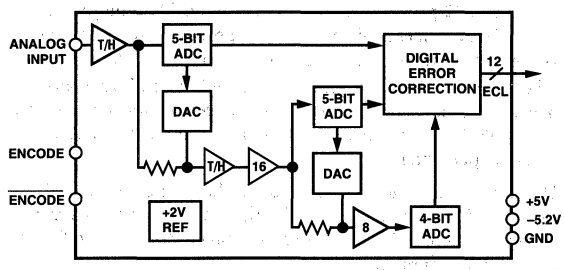
FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD9023 is a high speed, high performance, monolithic 12-bit analog-to-digital converter. All necessary functions, including track-and-hold (T/H) and reference, are included on chip to provide a complete conversion solution. It is a companion unit to the AD9023; the primary difference between the two is that all logic for the AD9022 is TTL compatible, while the AD9023 utilizes ECL logic for digital inputs and outputs. Pinouts for the two parts are nearly identical.

Operating from +5 V and –5.2 V supplies, the AD9023 provides excellent dynamic performance. Sampling at 20 Msps with A_{IN} = 1 MHz, the spurious free dynamic range (SFDR) is typically 80 dB; with A_{IN} = 9.6 MHz, SFDR is 74 dB. SNR is typically 65 dB.

The on-board T/H has a 100 MHz bandwidth and, more importantly, is designed to provide excellent dynamic performance for analog input frequencies above Nyquist. This feature is necessary in many undersampling signal processing applications, such as in direct IF to digital conversion.

To maintain dynamic performance at higher IFs, monolithic RF track-and-holds (such as the AD9100 and AD9101 Samplifier™) can be used with the AD9023 to process signals up to and beyond 70 MHz.

Samplifier is a trademark of Analog Devices, Inc.

With DNL typically less than 0.5 LSB and 20 ns transient response settling time, the AD9023 provides excellent results when low frequency analog inputs must be over-sampled (such as CCD digitization). The full-scale analog input is ±1 V with a 300 Ω input impedance. The analog input can be driven directly from the signal source, or can be buffered by the AD96xx series of low noise, low distortion buffer amplifiers.

All timing is internal to the AD9023; the clock signal initiates the conversion cycle. For best results, the encode command should contain as little jitter as possible. High speed layout practices must be followed to ensure optimum A/D performance.

The AD9023 is built on a trench isolated bipolar process and utilizes an innovative multipass architecture (see the block diagram). The unit is packaged in 28-pin ceramic DIPs and gullwing surface mount packages. The AD9023 is specified to operate over the industrial (–25°C to +85°C) and extended (–55°C to +125°C) temperature ranges.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

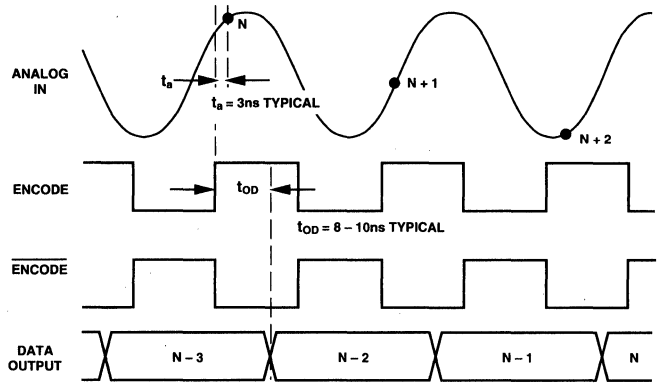
NOTES
[1]AD9023 load is a single LS latch.
[2]RMS signal-to-rms noise with analog input signal 1 dB below full scale at specified frequency.
[3]Intermodulation measured with analog input frequencies of 9.3 MHz and 9.6 MHz at 7 dB below full scale.
[4]PSRR is sensitivity of offset error to power supply variations within the 5% limits shown.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

$+V_S$ ..... +6 V
$-V_S$ ..... −6 V
Analog Input ..... $-V_S$ to $+V_S$
Digital Inputs ..... $-V_S$ to 0 V
Digital Output Current ..... 20 mA
Gain Adjust ..... $-V_S$ to $+V_S$
Offset Adjust ..... $-V_S$ to $+V_S$
Operating Temperature Range (Case)
AD9023AQ/AZ/BQ/BZ ..... −25°C to +85°C
AD9023SQ/SZ/TQ/TZ ..... −55°C to +125°C
Maximum Junction Temperature[2] ..... +175°C
Lead Temperature (Soldering, 10 sec) ..... +300°C
Storage Temperature Range ..... −65°C to +150°C

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Typical thermal impedances: "Q" Package (Ceramic DIP): θ_{JC} = 10°C/W; θ_{JA} = 35°C/W. "Z" Package (Gullwing Surface Mount): θ_{JC} = 13°C/W; θ_{JA} = 45°C/W.



Timing Diagram

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.

II – 100% production tested at +25°C, and sample tested at specified temperatures. AC testing done on sample basis.

III – Sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

VI – All devices are 100% production tested at +25°C; guaranteed by design and characterization testing at temperature extremes for industrial devices.

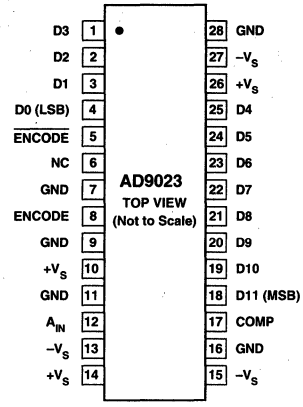
PIN DESCRIPTION

Pin No.	Name	Function
1–3	D3–D1	Digital output bits of ADC; ECL compatible.
4	D0 (LSB)	Least significant bit of ADC output; ECL compatible.
5	$\overline{\text{ENCODE}}$	Complementary encode input to ADC.
6	NC	No Connect
7	GND	Ground
8	ENCODE	Encode clock input to ADC. Internal T/H is placed in hold mode (ADC is encoding) on rising edge of encode signal.
9	GND	Ground
10	$+V_S$	+5 V Power Supply
11	GND	Ground
12	A_{IN}	Noninverting input to T/H amplifier.
13	$-V_S$	–5.2 V Power Supply
14	$+V_S$	+5 V Power Supply
15	$-V_S$	–5.2 V Power Supply
16	GND	Ground
17	COMP	Should be connected to $-V_S$ through 0.1 μF capacitor.
18	D11 (MSB)	Most significant bit of ADC output; ECL compatible.
19–25	D10–D4	Digital output bits of ADC; ECL compatible.
26	$+V_S$	+5 V Power Supply
27	$-V_S$	–5.2 V Power Supply
28	GND	Ground

PIN DESIGNATIONS



NC = NO CONNECT
COMPENSATION (PIN 17) SHOULD BE CONNECTED TO $-V_S$ THROUGH 0.01μF

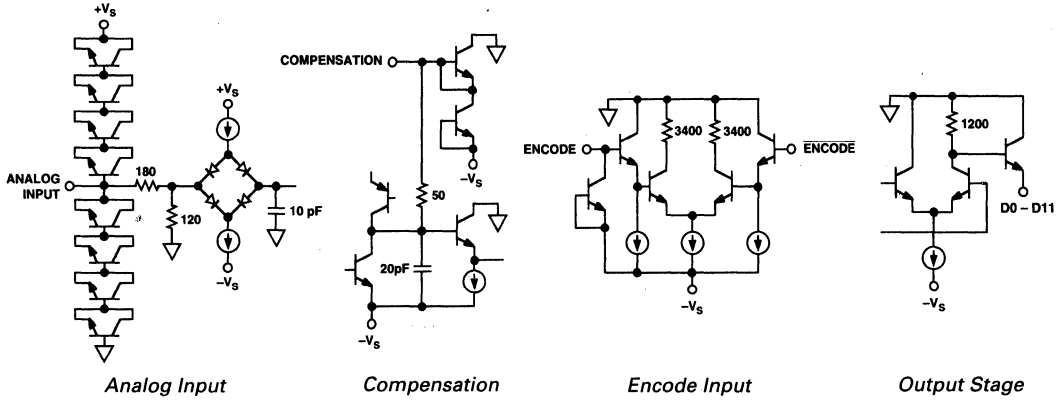


Figure 1. Equivalent Circuits

THEORY OF OPERATION

Refer to the block diagram. The AD9023 employs a three pass subranging architecture and digital error correction. This combination of design techniques insures 12-bit accuracy at relatively low power.

Analog input signals are immediately attenuated through a resistor divider and applied directly to the sampling bridge of the track-and-hold (T/H). The T/H holds whatever analog value is present when the unit is strobed with an ENCODE command. The conversion process begins on the rising edge of this pulse, which should conform to the minimum and maximum pulse width requirements shown in the specifications. Operation below the recommended encode rate (2 Msps) may result in excessive droop in the internal T/H devices–leading to large dc and ac errors.

The held analog value of the first track-and-hold is applied to a 5-bit flash converter and a second T/H. The 5-bit flash converter resolves the most significant bits (MSBs) of the held analog voltage. These 5 bits are reconstructed via a 5-bit DAC and subtracted from the original T/H output signal to form a residue signal.

A second T/H holds the amplified residue signal while it is encoded with a second 5-bit flash ADC. Again the 5 bits are reconstructed and subtracted from the second T/H output to form a residue signal. This residue is amplified and encoded with a 4-bit flash ADC to provide the 3 least significant bits (LSBs) of the digital output and one bit of error correction.

Digital Error Correction logic aligns the data from the three flash converters and presents the result as a 12-bit parallel digital word. The output stage of the AD9023 is TTL. Output data may be strobed on the rising edge of the ENCODE command.

AD9023 Noise Performance

High speed, wide bandwidth ADCs such as the AD9023 are optimized for dynamic performance over a wide range of analog input frequencies. However, there are many applications (Imaging, Instrumentation, etc.) where dc precision is also important. Due to the wide input bandwidth of the AD9023 for a given input voltage, there will be a range of output codes which may occur. This is caused by unavoidable circuit noise within the wideband circuits in the ADC. If a dc signal is applied to the ADC and several thousand outputs are recorded, a distribution of codes such as that shown in the histogram below may result.

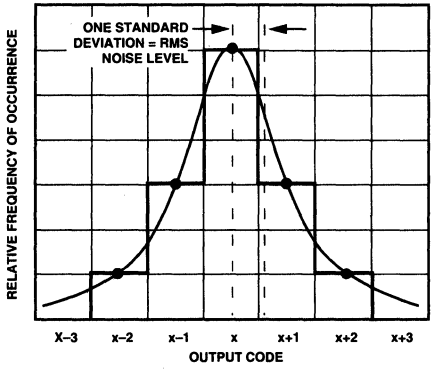

Figure 2. Equivalent Input Noise

The correct code appears most of the time, but adjacent codes also appear with reduced probability. If a normal probability density curve is fitted to this Gaussian distribution of codes, the standard deviation will be equal to the equivalent input rms noise of the ADC. The rms noise may also be approximated by converting the SNR, as measured by a low frequency FFT, to an equivalent input noise. This method is accurate only if the SNR performance is dominated by random thermal noise (the low frequency SNR without harmonics is the best measure). Sixty-three dB equates to 1 LSB rms for a 2 V p-p (0.707 V rms) input signal. The AD9023 has approximately 0.5 LSB of rms noise or a noise limited SNR of 69 dB, indicating that noise alone does not limit the SNR performance of the device (quantization noise and linearity are also major contributors).

This thermal noise may come from several sources. The drive source impedance should be kept low to minimize resistor thermal noise. Some of the internal ADC noise is generated in the wideband T/H. Sampling ADCs generally have input bandwidths which exceed the Nyquist frequency of one-half the sampling rate. (The AD9023 has an input bandwidth of over 100 MHz, even though the sampling rate is limited to 20 Msps.)

USING THE AD9023

Layout Information

Preserving the accuracy and dynamic performance of the AD9023 requires that designers pay special attention to the layout of the printed circuit board.

Analog paths should be kept as short as possible and be properly terminated to avoid reflections. The analog input connection should be kept away from digital signals paths; this reduces the amount of digital switching noise which is capacitively coupled into the analog section. Digital signal paths should also be kept short, and run lengths should be matched to avoid propagation delay mismatch. The AD9023 digital outputs should be buffered or latched close to the device (< 2 cm). This prevents load transients which may feed back into the device.

In high speed circuits, layout of the ground is critical. A single, low impedance ground plane on the component side of the board is recommended. Power supplies should be capacitively coupled to the ground plane with high quality 0.1 µF chip capacitors to reduce noise in the circuit. All power pins of the AD9023 should be bypassed individually. The compensation pin (COMP Pin 17) should be bypassed directly to the $-V_S$ supply (Pin 15) as close to the part as possible using a 0.1 µF chip capacitor.

Multilayer boards allow designers to lay out signal traces without interrupting the ground plane, and provide low impedance ground planes. In systems with dedicated analog and digital grounds, all grounds for the AD9023 should be connected to the analog ground plane.

In systems using multilayer boards, dedicated power planes are recommended to provide low impedance connections for device power. Sockets limit dynamic performance and are not recommended for use with the AD9023.

Timing

Conversion by the AD9023 is initiated by the rising edge of the ENCODE clock (Pin 8). All required timing is generated internal to the ADC. Care should be taken to ensure that the encode clock to the AD9023 is free from jitter that can degrade dynamic performance.

Pulse width of the ADC encode clock must be controlled to ensure the best possible performance. Dynamic performance is guaranteed with a clock pulse HIGH minimum of 25 ns. Operation with narrower pulses will degrade SNR and dynamic performance. From a system perspective, this is generally not a problem because a simple inverter can be used to generate a suitable clock if the system clock is less than 25 ns wide.

The AD9023 provides latched data outputs. Data outputs are available two pipeline delays and one propagation delay after the rising edge of the encode clock (refer to the AD9023 Timing Diagram). The length of the output data lines and the loads placed on them should be minimized to reduce transients within the AD9023; these transients can detract from the converter's dynamic performance. Operation at encode rates less than 2 Msps is not recommended. The internal track-and-hold saturates, causing erroneous conversions. This T/H saturation precludes clocking the AD9023 in a burst mode.

The duty cycle of the encode clock for the AD9023 is critical for obtaining rated performance of the ADC. Internal pulse widths within the track-and-hold are established by the encode command pulse width; to ensure rated performance, minimum and maximum pulse width restrictions should be observed. Operation at 20 Msps is optimized when the duty cycle is held at 50%. Duty cycle variations of less than ±5% will cause no degradation in performance at 20 Msps.

Analog Input

The analog input (Pin 12) voltage range is nominally ±1.024 volts. The range is set with an internal voltage reference and cannot be adjusted by the user. The input resistance is 300 Ω and the analog bandwidth is 100 MHz, making the AD9023 useful in undersampling applications.

The AD9023 should be driven from a low impedance source. The noise and distortion of the amplifier should be considered to preserve the dynamic range of the AD9023.

Power Supplies

The power supplies of the AD9023 should be isolated from the supplies used for noisy devices (digital logic especially) to reduce the amount of noise coupled into the ADC. For optimum performance, linear supplies ensure that switching noise from the supplies does not introduce distortion products during the encoding process. If switching supplies must be used, decoupling recommendations above are critically important. The PSRR of the AD9023 as a function of the ripple frequency present on the supplies is shown in the performance graphs. Clearly, power supplies with the lowest possible frequency should be selected.

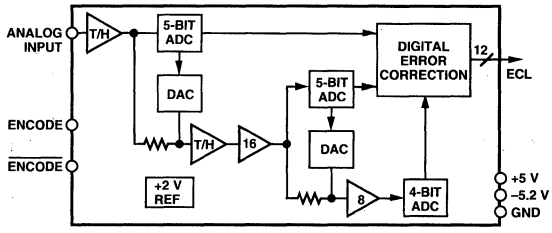
12-Bit, 31 MSPS Monolithic A/D Converter

AD9027

FEATURES
12-Bit 31 MSPS A/D Converter
Low Power Dissipation: 1.5 Watts
On-Chip T/H and Reference
Wide Spurious-Free Dynamic Range
ECL Logic

APPLICATIONS
Cellular Base Stations
Communications Receivers
Radar Receivers
Spectrum Analyzers
Electro-Optics
Medical Imaging

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD9027 is a high speed, high performance, monolithic 12-bit analog-to-digital converter. All necessary functions, including track-and-hold (T/H) and reference, are included on chip to provide a complete conversion solution.

It is a companion unit to the AD9026; the primary difference between the two is that all logic for the AD9026 is TTL compatible, while the AD9027 utilizes ECL logic for digital inputs and outputs. Pinouts for the two parts are nearly identical.

The on-board T/H has a 200 MHz bandwidth and, more importantly, is designed to provide excellent dynamic performance for analog input frequencies above Nyquist. This feature is necessary in many undersampling signal processing applications, such as in direct IF-to-digital conversion. In addition, wide spurious-free dynamic range (SFDR) over the entire Nyquist bandwidth makes the AD9027 well suited for multichannel transceiver applications which need to digitize bandwidths up to 15 MHz.

All timing is internal to the AD9027; the clock signal initiates the conversion cycle. For best results, the encode command should contain as little jitter as possible. High speed layout practices must be followed to ensure optimum A/D performance.

The AD9027 is built on a trench isolated bipolar process and utilizes an innovative multipass architecture (see the block diagram). The unit is packaged in a 28-pin ceramic DIP; the custom cofired ceramic package forms a multilayer substrate to which are attached internal bypass capacitors and the AD9027 die. The AD9027 is specified to operate over the industrial (–25°C to +85°C) temperature range.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]AD9027 is terminated into 5.2 V through 2,000 ohms.
[2]Analog input signal is 1 dB below full scale at specified frequency.
[3]Intermodulation measured with analog input frequencies of 9.6 MHz and 11.3 MHz at 7 dB below full scale.
[4]PSRR is sensitivity of offset error to power supply variations within the 5% limits shown.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

$+V_S$ ..... +6 V
$-V_S$ ..... –6 V
Analog Input ..... ±2.5 V
Digital Inputs ..... $-V_S$ to 0 V
Digital Output Current ..... 20 mA
Operating Temperature Range (Case) .....–25°C to +85°C
Maximum Junction Temperature[2] ..... +175°
Lead Temperature (Soldering, 10 sec) ..... +300°C
Storage Temperature Range .....–65°C to +150°C

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Typical thermal impedances: "Q" Package (Ceramic DIP): θ_{JC} = x°C/W; θ_{JA} = x°C/W.

ORDERING GUIDE

Device	Temperature Range	Package Option*
AD9027AD	–25°C to +85°C	DH-28

EXPLANATION OF TEST LEVELS

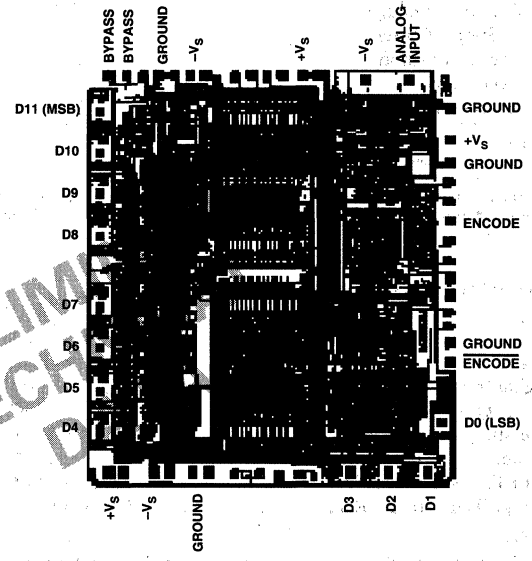
Test Level
I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures. AC testing done on sample basis.
III – Sample tested only.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% production tested at +25°C; 100% production tested at temperature extremes for extended temperature devices; guaranteed by design and characterization testing for industrial devices.

PIN DESCRIPTION

Pin No.	Name	Function
1–3	D3–D1	Digital output bits of ADC; ECL compatible.
4	D0 (LSB)	Least significant bit of ADC output; ECL compatible.
5	$\overline{\text{ENCODE}}$	Complement of encode clock input.
6	NC	No connection internally.
7	GND	Ground.
8	ENCODE	Encode clock input to ADC. Internal T/H is placed in hold mode (ADC is encoding) on rising edge of encode signal.
9	GND	Ground.
10	$+V_S$	+5 V power supply.
11	GND	Ground.
12	A_{IN}	Noninverting input to T/H amplifier.
13	$-V_S$	–5.2 V power supply.
14	$+V_S$	+5 V power supply.
15	$-V_S$	–5.2 V power supply.
16	GND	Ground.
17	BYPASS	Should be connected to $-V_S$ through 0.1 µF capacitor.
18	D11 (MSB)	Most significant bit of ADC output; ECL compatible.
19–25	D10–D4	Digital output bits of ADC; ECL compatible.
26	$+V_S$	+5 V power supply.
27	$-V_S$	–5.2 V power supply.
28	GND	Ground.

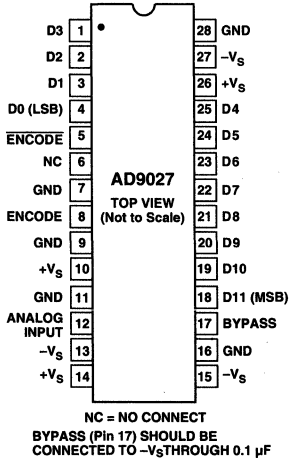
DIE LAYOUT AND MECHANICAL INFORMATION

Die Dimensions	205 × 228 × 21 (±1) mils
Pad Dimensions	4 × 4 mils
Metalization	Aluminum
Backing	None
Substrate Potential	$-V_S$
Transistor Count	4,336
Passivation	Oxynitride
Die Attach	Silver Filled
Bond Wire	Gold



AD9027 Chip Pinouts

PIN DESIGNATIONS



NC = NO CONNECT
BYPASS (Pin 17) SHOULD BE CONNECTED TO $-V_S$ THROUGH 0.1 µF

DEFINITIONS OF SPECIFICATIONS

Analog Bandwidth
The analog input frequency at which the spectral power of the fundamental frequency (as determined by FFT analysis) is reduced by 3 dB.

Aperture Delay
The delay between the 50% point of the rising edge of the ENCODE command and the instant at which the analog input is sampled.

Aperture Uncertainty (Jitter)
The sample-to-sample variation in aperture delay.

Differential Nonlinearity
The deviation of any code from an ideal 1 LSB step.

Harmonic Distortion
The rms value of the fundamental divided by the rms value of the worst harmonic component.

Integral Nonlinearity
The deviation of the transfer function from a reference line measured in fractions of 1 LSB using a "best straight line" determined by a least square curve fit.

Minimum Conversion Rate
The encode rate at which the SNR of the lowest analog signal frequency tested drops by no more than 3 dB below the guaranteed limit.

Maximum Conversion Rate
The encode rate at which parametric testing is performed.

Output Propagation Delay
The delay between the 50% point of the rising edge of the ENCODE command and the time when all output data bits are within valid logic levels.

Overvoltage Recovery Time
The amount of time required for the converter to recover to 12-bit accuracy after an analog input signal 150% of full scale is reduced to midscale.

Power Supply Rejection Ratio (PSRR)
The ratio of a change in input offset voltage to a change in power supply voltage.

Signal-to-Noise-and-Distortion (SINAD)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, including harmonics but excluding dc, with an analog input signal 1 dB below full scale.

Signal-to-Noise Ratio (Without Harmonics)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, excluding the first five harmonics and dc, with an analog input signal 1 dB below full scale.

Transient Response
The time required for the converter to achieve 12-bit accuracy when a one-half full-scale step function is applied to the analog input.

Two-Tone Intermodulation Distortion (IMD) Rejection
The ratio of the power of either of two input signals to the power of the strongest third-order IMD signal.

Equivalent Circuits

THEORY OF OPERATION

Refer to the block diagram.

The AD9027 employs a three-pass subranging architecture and digital error correction. This combination of design techniques ensures 12-bit accuracy at relatively low power.

Analog input signals are immediately attenuated through a resistor divider and applied directly to the sampling bridge of the track-and-hold (T/H). The T/H holds whatever analog value is present when the unit is strobed with an ENCODE command. The conversion process begins on the rising edge of this pulse, which should conform to the minimum and maximum pulse width requirements shown in the specifications. Operation below the recommended encode rate (4 Msps) may result in excessive droop in the internal T/H devices—leading to large dc and ac errors.

The held analog value of the first track-and-hold is applied to a 5-bit flash converter and a second T/H. The 5-bit flash converter resolves the most significant bits (MSBs) of the held analog voltage. These five bits are reconstructed via a 5-bit DAC and subtracted from the original T/H output signal to form a residue signal.

A second T/H holds the amplified residue signal while it is encoded with a second 5-bit flash ADC. Again the five bits are reconstructed and subtracted from the second T/H output to form a residue signal. This residue is amplified and encoded with a 4-bit flash ADC to provide the three least significant bits (LSBs) of the digital output and one bit of error correction.

Digital error correction logic aligns the data from the three flash converters and presents the result as a 12-bit parallel digital word. The output stage of the AD9027 is ECL. Output data may be strobed on the rising edge of the ENCODE command.

AD9027 NOISE PERFORMANCE

High speed, wide bandwidth ADCs such as the AD9027 are optimized for dynamic performance over a wide range of analog input frequencies. However, there are many applications (imaging, instrumentation, etc.) where dc precision is also important. Due to the wide input bandwidth of the AD9027 for a given input voltage, there will be a range of output codes that may occur. This is caused by unavoidable circuit noise within the wideband circuits in the ADC. If a dc signal is applied to the ADC and several thousand outputs are recorded, a distribution of codes such as that shown in the histogram may result.

The correct code appears most of the time, but adjacent codes also appear with reduced probability. If a normal probability density curve is fitted to this Gaussian distribution of codes, the standard deviation will be equal to the equivalent input rms noise of the ADC. The rms noise may also be approximated by converting the SNR, as measured by a low frequency FFT, to an equivalent input noise. This method is accurate only if the SNR performance is dominated by random thermal noise (the low frequency SNR without harmonics is the best measure); 63 dB equates to 1 LSB rms for a 2 V p-p (0.707 V rms) input signal.

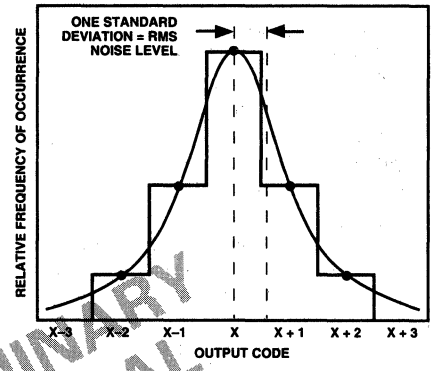

Figure 1. ADC Equivalent Input Noise

The AD9027 has approximately 0.7 LSB of rms noise or a noise limited SNR of 66 dB, indicating that thermal noise alone does not limit the SNR performance of the device (quantization noise and linearity are also major contributors).

This thermal noise may come from several sources. The drive source impedance should be kept low to minimize resistor thermal noise. Some of the internal ADC noise is generated in the wideband T/H. Sampling ADCs generally have input bandwidths which exceed the Nyquist frequency of one-half the sampling rate. (The AD9027 has an input bandwidth of approximately 200 MHz, even though the sampling rate is limited to 31 Msps.)

Wide bandwidth is required to minimize gain and phase distortion and to permit adequate settling times in the internal amplifiers and T/Hs. But a certain amount of unavoidable noise is generated in the T/H and other wideband circuits within the ADC; this causes variation in output codes for dc inputs. Good layout, grounding, and decoupling techniques are essential to prevent external noise from coupling into the ADC and further corrupting performance.

USING THE AD9027

Layout Information

Preserving the accuracy and dynamic performance of the AD9027 requires that designers pay special attention to the layout of the printed circuit board.

Analog paths should be kept as short as possible and be properly terminated to avoid reflections. The analog input connection should be kept away from digital signals paths; this reduces the amount of digital switching noise which is capacitively coupled into the analog section. Digital signal paths should also be kept short, and run lengths should be matched to avoid propagation delay mismatch. The AD9027 digital outputs should be buffered or latched close to the device (< 2 cm). This prevents load transients which may feed back into the device.

In high speed circuits, layout of the ground is critical. A single, low impedance ground plane on the component side of the board is recommended. Power supplies should be capacitively coupled to the ground plane with high quality 0.1 µF chip capacitors to reduce noise in the circuit. All power pins of the AD9027 should be bypassed individually. The bypass pin (BYPASS Pin 17) should be bypassed directly to the $-V_S$ supply (Pin 15) as close to the part as possible using a 0.1 µF chip capacitor.

Multilayer boards allow designers to lay out signal traces without interrupting the ground plane, and provide low impedance ground planes. In systems with dedicated analog and digital grounds, all grounds for the AD9027 should be connected to the analog ground plane.

In systems using multilayer boards, dedicated power planes are recommended to provide low impedance connections for device power. Sockets limit dynamic performance and are not recommended for use with the AD9027.

Timing

Conversion by the AD9027 is initiated by the rising edge of the ENCODE clock (Pin 8). All required timing is generated internal to the ADC. Care should be taken to ensure that the encode clock to the AD9027 is free from jitter that can degrade dynamic performance. The clock driver should be differential ECL. Drivers with excessive slew rate or overdrive will degrade the dynamic performance of the AD9027.

Pulse width of the ADC encode clock must be controlled to insure the best possible performance. The duty cycle of the encode clock for the AD9027 is critical for obtaining rated performance of the ADC. Internal pulse widths within the track-and-hold are established by the encode command pulse width; to ensure rated performance, minimum and maximum pulse width restrictions should be observed. Operation at 31 Msps is optimized when the duty cycle is held at 50%. Duty cycle variations of less than ±5% will cause no degradation in performance at 31 Msps.

The AD9027 provides latched data outputs. Data outputs are available two pipeline delays and one propagation delay after the rising edge of the encode clock (refer to the AD9027 Timing Diagram). The length of the output data lines and the loads placed on them should be minimized to reduce transients within the AD9027; these transients can detract from the converter's dynamic performance.

Operation at encode rates less than 4 Msps is not recommended. The internal track-and-hold saturates, causing erroneous conversions. This T/H saturation precludes clocking the AD9027 in a burst mode.

Analog Input

The Analog Input (Pin 12) voltage range is nominally ±1.024 V. The range is set with an internal voltage reference and can not be adjusted by the user. The input resistance is 300 Ω and the analog bandwidth is 200 MHz, making the AD9027 useful in undersampling applications.

The AD9027 should be driven from a low impedance source. The noise and distortion of the amplifier should be considered to preserve the dynamic range of the AD9027.

Power Supplies

The power supplies of the AD9027 should be isolated from the supplies used for noisy devices (digital logic especially) to reduce the amount of noise coupled into the ADC. For optimum performance, linear supplies ensure that switching noise from the supplies does not introduce distortion products during the encoding process. If switching supplies *must* be used, decoupling recommendations above are critically important. The PSRR of the AD9027 as a function of the ripple frequency present on the supplies is shown in the performance graphs. Clearly, power supplies with the lowest possible frequency should be selected.

ANALOG DEVICES

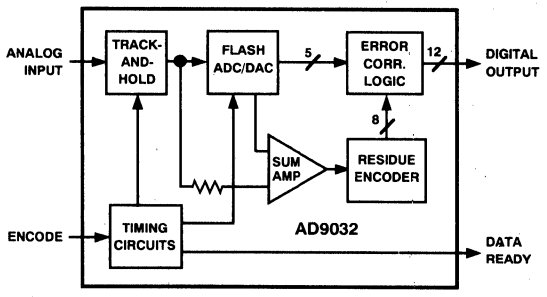
12-Bit 25 MSPS A/D Converter

AD9032

FEATURES
25.6 MSPS Conversion Speeds
On-Board T/H, References, Timing
Low Power: 3.8 W
Single 40-Pin Package
74 dB Spurious-Free Dynamic Range to 12 MHz A_{IN}
Bipolar Input: ±1.024 V

APPLICATIONS
Radar
Signal Intelligence
Digital Spectrum Analyzers
Medical Imaging
Electro-Optics

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9032 is the world's fastest 12-bit analog-to-digital converter (ADC) that includes on-board T/H, voltage references, and timing circuits. The AD9032 uses a subranging converter architecture to achieve sample rates from dc to 25.6 Msps. Packaged in a single 40-pin hybrid, the AD9032 is pin-compatible with the AD9034, which operates at word rates up to 20 Msps.

This ECL-compatible ADC requires only +5 V and −5.2 V supplies, an analog input, and a stable ECL clock to obtain the best dynamic performance available in a 12-bit ADC. This kind of performance is achieved with advanced bipolar circuits, custom designed and manufactured by Analog Devices. The latest in monolithic track-and-hold technology ensures accurate sampling of high frequency analog inputs.

Dynamic performance has been optimized to achieve SNR of 64 dB and a spurious-free dynamic range (SFDR) of 74 dB for analog bandwidths up to 12 MHz. All units are tested for dynamic performance at a sample rate of 25.6 Msps.

The AD9032 is available in either a 40-pin ceramic DIP or leaded flatpack. The two versions operate over an industrial (−25°C to +85°C) or military (−55°C to +125°C) temperature range.

EVALUATION BOARD

An evaluation board which is available for the AD9032 (part number AD9034/PCB) provides an easy and flexible method for evaluating the ADC's performance without (or prior to) developing a user-specified printed circuit board. The evaluation board was originally designed and used for evaluating the AD9034 A/D converter, but is equally useful for the pin-compatible AD9032.

The board includes a reconstruction DAC, analog input amplifier, and digital output interface. Physically, it is 7.25 inches × 6 inches in size and uses the layout and applications information contained in the AD9034 data sheet.

Generous space is provided near the analog input and digital outputs of the evaluation board to support additional signal processing components the user may wish to add. These two prototyping areas include through holes with 100-mil centers to support a variety of component additions.

For additional operating details, a schematic of the evaluation board, and complete layout information, consult the data sheet on the AD9034 A/D converter.

DEFINITIONS OF SPECIFICATIONS

Analog Bandwidth
The analog input frequency at which the spectral power of the fundamental frequency (as determined by FFT analysis) is reduced by 3 dB.

Aperture Delay (t_A)
The delay between the rising edge of the ENCODE command and the instant at which the analog input is sampled.

Aperture Uncertainty (Jitter)
The sample-to-sample variation in aperture delay.

Data Ready Delay (t_{DR})
The delay between the 50% point of the change in output data and the 50% point of the rising edge of DATA READY.

Differential Nonlinearity (DNL)
The deviation of any code width from an ideal 1 LSB step, as determined by a histogram.

Harmonic Distortion
The rms value of the fundamental divided by the rms value of the worst harmonic.

Integral Nonlinearity (INL)
The deviation of the transfer function from a reference line measured in fractions of 1 LSB using a "best straight line" determined by a least square curve fit, as determined by a histogram.

Output Delay (t_{OD})
The delay between the 50% point of the rising edge of the ENCODE command and the 50% point of the next change in output data.

Output Time Skew
Bit-to-bit time variations among D_0 to D_{11} outputs. Time skew includes HIGH-to-LOW and LOW-to-HIGH transitions of the digital output bits.

Overvoltage Recovery Time
The amount of time required for the converter to recover to 12-bit accuracy after an analog input signal 150% of full scale is reduced to the midscale of the converter.

Power Supply Rejection Ratio
The ratio of a change in power supply voltage which results in a change in input offset voltage.

Pulse Width (High and Low)
Rated performance of the ADC is assured when stated restrictions on ENCODE pulse width shown in Specifications table are observed.

Signal-to-Noise Ratio (SNR)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, including harmonics but excluding dc, with an analog input signal 1 dB below full scale.

Spurious Free Dynamic Range (SFDR)
The rms value of the fundamental divided by the rms value of the highest spurious signal. This is generally specified as a function of input signal level.

Transient Response
The time required for the converter to achieve 12-bit accuracy when a full-scale step function is applied to the analog input.

Two-Tone Intermodulation Distortion (IMD) Rejection
The ratio of the power of either of two input signals to the power of the strongest third-order IMD signal.

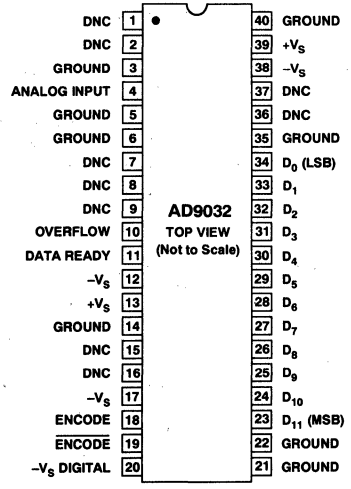
PIN DESCRIPTIONS

Pin	Name	Description
1	GAIN ADJUST	Can be used to null out initial gain error of ADC. Normally open.
2	OFFSET ADJUST	Can be used to null out initial offset error of ADC. Normally open.
3, 5, 6, 14, 21, 22, 35, 40	GROUND	All ground pins should be connected together and to low-impedance ground plane near AD9034.
4	ANALOG INPUT	Analog input to ADC, ±1.024 V input range; 100 Ω input resistance; 7 pF input capacitance.
7, 8, 9, 15 16, 36, 37	DNC	Do not connect. Internal test points.
10	OVERFLOW	ECL-compatible output; normally low. High when analog input > +FS.
11	DATA READY	ECL-compatible output. Rising edge of signal suitable, for externally latching $D_0 - D_{11}$.
12, 17, 20, 38	$-V_S$	−5.2 V supply voltage.
13, 39	$+V_S$	+5.0 V supply voltage.
18	ENCODE	Differential ECL convert command.
19	$\overline{\text{ENCODE}}$	Sampling occurs on rising edge; no internal terminations.
23–34	D_0–D_{11}	ECL-compatible digital outputs; 2s complement coding.

PIN DESIGNATIONS



THEORY OF OPERATION

The AD9032 is a digitally corrected subranging analog-to-digital converter (ADC) optimized for fast sampling rates and dynamic range. Refer to the block diagram on the first page. The AD9032 is a vertically integrated structure consisting of a track-and-hold (T/H) amplifier, a combined flash ADC and digital-to-analog (DAC), a summation amplifier, digital error correction logic, and timing circuits. Reference circuits to generate stable DC voltages and currents that maintain the static accuracy of the device are also included, but are not shown on the block diagram.

Internally, the monolithic T/H (AD9101) provides fast settling and acquisition times while minimizing distortion introduced by the sampling process. The unique design of the sampling bridge allows accurate sampling of high slew rate signals with negligible distortion. The effects of jitter and other aperture errors have been reduced to provide dynamic performance previously unavailable in monolithic and discrete designs.

At the output of the T/H amplifier, the analog input is converted by the first (5-bit) ADC. This 5-bit representation of the input value is stored in the digital error correction logic. It is also converted back to an analog signal by the 14-bit-accurate DAC on the same chip with the ADC. The 32 DAC current sources are steered directly by the outputs of the 32 input comparators on the 5-bit ADC. This minimizes propagation delay through the DAC, and allows the summation of the DAC signal and the held output of the T/H to settle quickly. The hold time of the T/H is optimized to allow sufficient settling time without sacrificing the acquisition time necessary to acquire the next sample.

The residue signal, representing the difference between the 5-bit conversion (DAC output) and the input signal held by the T/H, is amplified by the summation amplifier. During the tracking period of the T/H, this residue signal can be much larger than the input range of the 8-bit ADC and would saturate the output stage of a normal amplifier. To protect the ADC and maintain fast settling times under all conditions, the summation amplifier is a custom design with clamping circuits that prevent saturation, limit the output voltage, and preserve settling time.

The 8-bit flash ADC determines the 7 least significant bits (LSBs) of the 12-bit conversion and generates a correction bit for any small errors created by inaccuracies in the first 5-bit conversion. This 8-bit signal and the 5-bit quantization are combined to obtain a 12-bit-accurate representation of the analog input voltage.

USING THE AD9032

Layout Information

Preserving the accuracy and dynamic performance of the AD9032 requires that designers pay special attention to the layout of the printed circuit board. Signal paths should be impedance matched and properly terminated at or near the package connections. Analog signal paths should be isolated from digital signal paths. Capacitive and inductive coupling of digital signals into analog signal sections can degrade the overall performance of the A/D converter.

Analog Input

The analog input pin of the AD9032 is terminated with a 100 Ω load. The analog input range of the AD9032 is factory trimmed for a ±1.024 V input for compatibility with the AD9034. The signal presented to the monolithic T/H is divided in half to optimize dynamic performance.

When the amplitude, bandwidth, or dc level of the analog input requires external signal conditioning, the selection of the input amplifier is of particular concern. The noise and distortion of the amplifier must be taken into account to preserve the dynamic range of the AD9032. The AD9617 wideband, current feedback amplifier is an excellent choice for most applications.

Timing

Internal timing for the AD9032 is trimmed at the factory to simplify use. Care should be taken to ensure that the encode command to the AD9032 is free from jitter that can degrade dynamic performance. Differential ECL inputs to the AD9032 can be derived from a single-ended source using a fast comparator such as the AD96685. The encode source should be located and terminated as close to the AD9032 as possible.

The ECL-compatible digital outputs are latched to provide valid data for the entire conversion period (less the transition region of latch). This data should be latched into external ECL registers located near the AD9032. External termination resistors are required (510 Ω recommended). The data are latched with either the encode command or the data ready signal provided on the AD9032. The rising edge of the data ready signal occurs typically 7.5 ns after the data changes.

Gain and Offset Adjustment

Gain and offset pins are normally not connected. Rated performance is guaranteed without any external connection to these pins. In most applications, wide variations in input signal range and offset can be accommodated using external amplifiers. However, in those applications where a vernier adjustment is required (such as nulling out factory trim limits), the gain and offset pins will provide sufficient adjustment range.

Both inputs offer a 20 kΩ input resistance that can be driven from a voltage source (DAC, amplifier) or the center tap of a potentiometer. The offset pin provides a 195 mV/V sensitivity to input offset, while the gain pin offers 120 mV/V adjustment of the full-scale input range of the ADC. The adjustment range for offset is limited to 10 mV and for gain is 20 mV without introducing potential dynamic errors or restricting the operating temperature range of the part.

Power Supplies

The unique design of the AD9032 provides excellent dynamic performance without a need for high voltage power supplies. Two supplies (+5 V and −5.2 V) are all that are required to achieve rated performance. Careful layout and decoupling of power supplies used in conjunction with a low impedance analog ground plane will reduce supply-related noise components.

Separate analog and digital supplies are not required. In applications with only limited analog supply current, a separate digital supply source can be used for the −5.2 V supply on Pin 20. This supply typically requires 310 mA (330 mA max) and may be shared with other ECL logic devices when isolated with bypass capacitors and/or ferrite bead inductors (Fair-Rite Products Corporation part # 2743001111, Wallkill, NY). Each power supply pin should be capacitively decoupled to the ground plane through a good high frequency ceramic capacitor (0.1 μF) and a single large value capacitor (tantalum 10 μF).

For optimum performance, "clean" linear supplies ensure that switching noise on the supplies does not introduce distortion products during the encoding process. Recognizing, however, that switching power supplies may be required in power-sensitive applications, decoupling recommendations outlined above are critically important for using switching supplies effectively. Elsewhere in this data sheet, a graph shows the PSRR of the AD9032 as a function of the ripple frequency present on the AD9032 supplies. Clearly, if they must be used, switching power supplies with the lowest possible frequency should be selected.

Thermal Management

The AD9032 design minimizes power dissipation; however, the ADC does typically require 3.8 W (4.5 W max) to operate. To ensure long life and reliable operation, the maximum junction temperature in the AD9032 must be limited to +175°C.

Within the hybrid, the hottest discrete die has a case to junction temperature rise of 10°C (max). Therefore, the case temperature of the AD9032 should not exceed +165°C under worst case operating conditions. Without airflow, the θ_{CA} of the hybrid package is 13°C/W. Assuming maximum power dissipation, this causes a 57°C rise in case temperature over the ambient air temperature. The maximum still air temperature, therefore, is equal to +108°C.

Rated performance of the AD9032 is guaranteed for case operating temperatures of +85°C (AD9032A/B) and +125°C (AD9032T). This equates to a maximum operating ambient temperature of +28°C and +68°C, respectively, in still air. In most applications, airflow is recommended. The following improvements in the thermal characteristics of the system assume that the AD9032 is soldered to a PC board.

The θ_{CA} of the hybrid is reduced to 5°C/W with 500 LFPM airflow. This will extend the rated performance to ambient operating ranges of +63°C for the AD9032A/B and +103°C for the AD9032T. The addition of a heat sink (Thermalloy #6087B, Dallas, Texas; phone 214-243-0839) will further improve the thermal transfer of the hybrid to 3°C/W (@ 500 LFPM). Using a heat sink with airflow, the total case to ambient temperature rise is only 13°C, which results in a maximum ambient environment of +72°C (AD9032A/B) and +112°C (AD9032T).

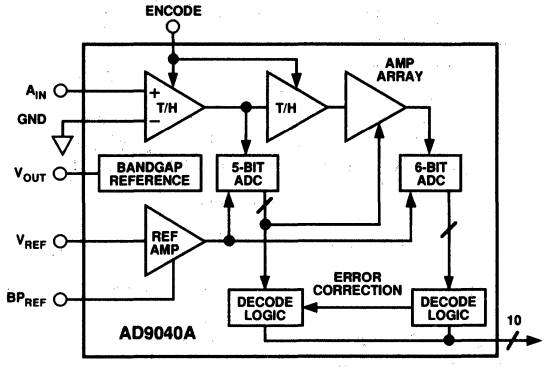
FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9040A is a complete 10-bit monolithic sampling analog-to-digital converter (ADC) with on-board track-and-hold and reference. The unit is designed for low cost, high performance applications and requires only an encode signal to achieve 40 Msps sample rates with 10-bit resolution.

Digital inputs and outputs are CMOS compatible; the analog input requires a signal of 2 V p-p amplitude. The two-step architecture used in the AD9040A is optimized to provide the best dynamic performance available while maintaining low power requirements of only 940 mW typically; maximum dissipation is 1.1 watt at 40 Msps.

The signal-to-noise ratio (SNR), including harmonics, is 53 dB, or 8.5 ENOB, when sampling an analog input of 10.3 MHz at 40 Msps. Competitive devices perform at less than 7.5 ENOB and require external references and larger input signals.

The AD9040A A/D converter is available as either a 28-pin plastic DIP or a 28-pin SOIC. The two models operate over a commercial temperature range of 0°C to +70°C. Contact the factory regarding availability of ceramic military temperature range devices.

PRODUCT HIGHLIGHTS

1. CMOS compatible logic for direct interface to ASICs.
2. On-board T/H provides excellent high frequency performance on analog inputs, critical for communications and medical imaging applications.
3. High input impedance and 2 volt p-p input range reduce need for external amplifiers.
4. Easy to use; no cumbersome external voltage references required, allowing denser packing of ADCs for multi-channel applications.
5. Available in 28-lead plastic DIP and SOIC packages.
6. Evaluation board includes AD9040AJR, reconstruction DAC, and latches. Space is available near the analog input and digital outputs of the converter for additional circuits. Order as part number AD9040A/PCB (schematic shown in data sheet).

NOTES

[1]"Gain Tempco" is for converter using internal reference; "Temperature Coefficient" is for bandgap reference only.

[2]Output propagation delay (t_{PD}) is measured from the 50% point of the falling edge of the encode command to the min/max voltage levels of the digital outputs with 10 pF maximum loads.

[3]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.

[4]ENCODE = 32 Msps.

[5]3rd order intermodulation measured with analog input frequencies of 2.3 MHz and 2.4 MHz at 7 dB below full scale.

[6]For rated performance at 40 Msps, duty cycle of encode command should be 50% ±10%.

[7]Measured as the ratio of the change in offset voltage for a 5% change in $+V_S$ or $-V_S$.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I — 100% Production Tested.

II — 100% production tested at +25°C, and sample tested at specified temperatures. AC testing done on sample basis.

III — Sample Tested Only.

IV — Parameter is guaranteed by design and characterization testing.

V — Parameter is a typical value only.

VI — All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for military temperature devices; guaranteed by design and characterization testing for industrial devices.

ABSOLUTE MAXIMUM RATINGS[1]

$\pm V_S$ . . . . . ±7 V
V_D . . . . . +7 V
ANALOG IN . . . . . $-V_S$ to $+V_S$
DIGITAL INPUTS . . . . . 0 V to $+V_S$
V_{REF} Input . . . . . 0 V to $+V_S$
Digital Output Current . . . . . 20 mA
Operating Temperature
AD9040AJN/JR . . . . . 0°C to +70°C
Storage Temperature . . . . . −65°C to +150°C
Maximum Junction Temperature[2] (JN/JR Suffixes) . . . +150°C
Lead Soldering Temp (10 sec) . . . . . +300°C

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]Typical thermal impedances (parts soldered to board):
N Package (Plastic DIP): θ_{JA} = 42°C/W; θ_{JC} = 10°C/W.
R Package (SOIC): θ_{JA} = 47°C/W; θ_{JC} = 10°C/W.

ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option*
AD9040AJN	0°C to +70°C	28-Pin Plastic DIP	N-28
AD9040AJR	0°C to +70°C	28-Pin SOIC Package	R-28

DEFINITIONS OF SPECIFICATIONS

Analog Bandwidth
The analog input frequency at which the spectral power of the fundamental frequency (as determined by FFT analysis) is reduced by 3 dB.

Aperture Delay
The delay between the rising edge of the ENCODE command and the instant at which the analog input is sampled.

Aperture Uncertainty (Jitter)
The sample-to-sample variation in aperture delay.

Differential Gain
The percentage of amplitude change of a small high frequency sine wave (3.58 MHz) superimposed on a low frequency signal (15.734 kHz).

Differential Nonlinearity
The deviation of any code from an ideal 1 LSB step.

Differential Phase
The phase change of a small high frequency sine wave (3.58 MHz) superimposed on a low frequency signal (15.734 kHz).

Harmonic Distortion
The rms value of the fundamental divided by the rms value of the harmonic.

Integral Nonlinearity
The deviation of the transfer function from a reference line measured in fractions of 1 LSB using a "best straight line" determined by a least square curve fit.

Minimum Conversion Rate
The encode rate at which the SNR of the lowest analog signal frequency tested drops by no more than 3 dB below the guaranteed limit.

Maximum Conversion Rate
The encode rate at which parametric testing is performed.

Output Propagation Delay
The delay between the 50% point of the falling edge of the ENCODE command and the 1 V/4 V points of output data.

Overvoltage Recovery Time
The amount of time required for the converter to recover to 10-bit accuracy after an analog input signal 150% of full scale is reduced to the full-scale range of the converter.

Power Supply Rejection Ratio (PSRR)
The ratio of a change in input offset voltage to a change in power supply voltage.

Signal-to-Noise Ratio (SNR)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, including harmonics but excluding dc, with an analog input signal 1 dB below full scale.

Signal-to-Noise Ratio (Without Harmonics)
The ratio of the rms signal amplitude to the rms value of "noise," which is defined as the sum of all other spectral components, excluding the first eight harmonics and dc, with an analog input signal 1 dB below full scale.

Transient Response
The time required for the converter to achieve 10-bit accuracy when a step function is applied to the analog input.

Two-Tone Intermodulation Distortion (IMD) Rejection
The ratio of the power of either of two input signals to the power of the strongest third-order IMD signal.

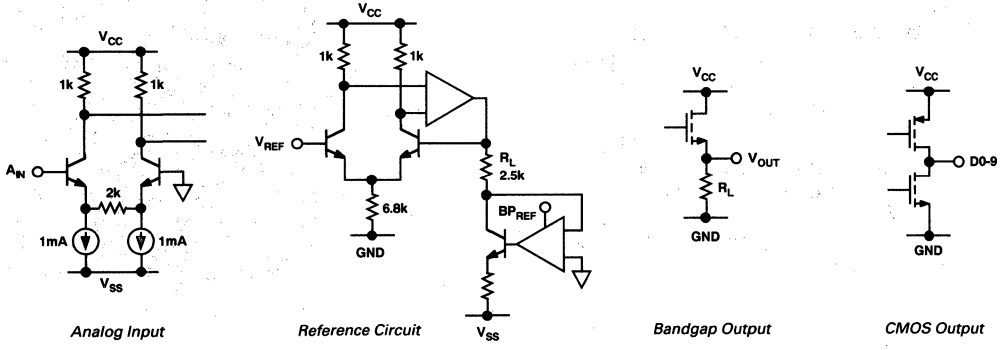

Figure 1. Equivalent Circuits

THEORY OF OPERATION

Refer to the block diagram.

The AD9040A employs subranging architecture and digital error correction. This combination of design techniques insures true 10-bit accuracy at the digital outputs of the converter.

At the input, the analog signal is applied to a track-and-hold (T/H) that holds the analog value which is present when the unit is strobed with an ENCODE command. The conversion process begins on the rising edge of this pulse, which should have a 50% (±10%) duty cycle. Minimum encode rate of the AD9040A is 10 Msps because of the use of three internal T/H devices.

The held analog value of the first track-and-hold is applied to a 5-bit flash converter and a pair of internal T/Hs (shown in the block diagram as a single unit). The T/Hs pipeline the analog signal to the amplifier array through a residue ladder and switch ing circuit while the 5-bit flash converter resolves the most significant bits (MSBs) of the held analog voltage.

When the 5-bit flash converter has completed its cycle, its output activates 1-of-32 ladder switches; these, in turn, cause the correct residue signal to be applied to the error amplifier array.

The output of the error amplifier is applied to a 6-bit flash converter whose output supplies the five least significant bits (LSBs) of the digital output along with one bit of error correction for the 5-bit main range converter.

Decode logic aligns the data from the two converters and presents the result as a 10-bit parallel digital word. The output stage of the AD9040A is CMOS. Output data are strobed on the trailing edge of the ENCODE command.

Full-scale range of the AD9040A is determined by the reference voltage applied to the V_{REF} (Pin 6) input. This voltage sets the internal flash and residue ladder voltage drops; these establish the value of the LSB. Because of headroom restraints, the full-scale range cannot be increased by applying a higher-than-specified reference voltage. Conversely, a lower reference voltage will reduce the full-scale range of the converter, but will also decrease its performance. An internal bandgap reference voltage of +2.5 V is provided to assure optimum performance over the operating temperature range.

USING THE AD9040A

Timing

The duty cycle of the encode clock for the AD9040A is critical for obtaining rated performance of the ADC. Internal pulse widths within the track-and-hold are established by the encode command pulse width; to ensure rated performance, the duty cycle should be held at 50%. Duty cycle variations of less than ±10% will cause no degradation in performance.

Operation at encode rates less than 10 Msps is not recommended. The internal track-and-hold saturates, causing erroneous conversions. This T/H saturation precludes clocking the AD9040A in burst mode. The 50% duty cycle must be maintained even for sample rates down to 10 Msps.

The AD9040A provides latched data outputs, with 2 1/2 pipeline delays. Data outputs are available one propagation delay (t_{PD}) after the falling edge of the encode command (refer to AD9040A Timing Diagram). The length of the output data lines and the loads placed on them should be minimized to reduce transients within the AD9040A; these transients can detract from the converter's dynamic performance.

Voltage Reference

A stable voltage reference is required to establish the 2-V p-p range of the AD9040A. There are two options for creating this reference. The easiest and least expensive way to implement it is to use the (+2.5 V) bandgap voltage reference which is internal to the ADC. Figure 2 illustrates the connections for using the internal reference. The internal reference has 500 μA of extra drive current which can be used for other circuits.

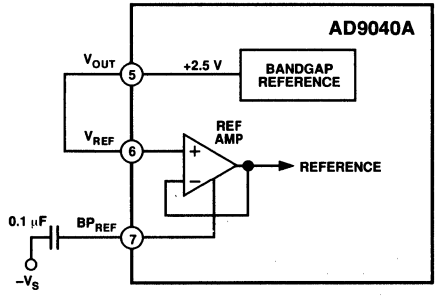

Figure 2. AD9040A Using Internal Reference

Some applications may require greater accuracy, improved temperature performance, or adjustment of the gain (input range) of the AD9040A which cannot be obtained by using the internal reference. For these applications, an external +2.5 V reference can be used, as shown in Figure 3. The V_{REF} input requires 5 μA of drive current.

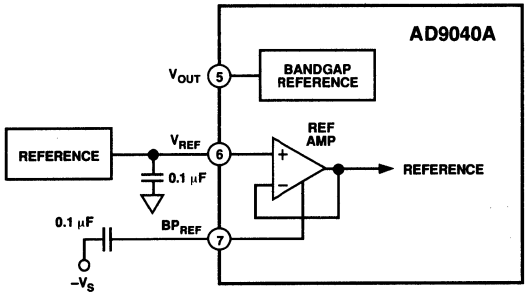

Figure 3. AD9040A Using External Reference

In applications using multiple AD9040As, slaving the reference inputs to a single reference output will improve gain tracking among the ADCs, as shown in Figure 4.

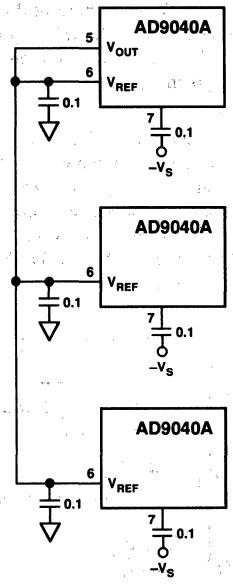

Figure 4. Slaving Multiple AD9040As to a Single Internal Reference

In the specifications table, the Gain Tempco parameter under DC ACCURACY applies to the ADC when the internal reference is being used. If an external reference is used, its temperature coefficient must be taken into account to determine overall temperature performance.

The input range can be varied by adjusting the reference voltage applied to the AD9040A. By decreasing the reference voltage, the gain can be reduced approximately 10% with no degradation in performance. Increasing the reference voltage increases the gain; but for proper operation, the reference voltage should not exceed +2.6 V.

X-AMP is a trademark of Analog Devices, Inc.

Time-Gain Control ADC

Ultrasound and sonar systems require an increase in gain versus time. This allows the system to correct for attenuation of return pulses. Figure 5 shows the AD600/602 amplifier and the AD9040A ADC configured as a time-gain control analog-to-digital converter. The control voltage ramps from −625 mV to +625 mV, permitting 40 dB of gain-control range. The voltage used for gain control can be either a linear ramp, or the output of a voltage-output DAC such as the AD7242.

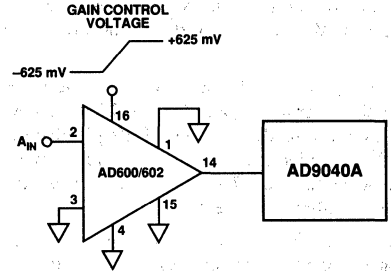

Figure 5. Ultrasound/Sonar Time-Gain Control ADC Using X-AMPs™

Transient Response

Figure 6 illustrates the method for evaluating ADC transient performance. Two synthesizers are locked in synchronization, but tuned to frequencies which are slightly offset from a 2-to-1 submultiple.

One synthesizer clocks a flat pulse network at a frequency of 19.9609375 MHz to provide the analog input signal; the other synthesizer output is shaped to provide a CMOS 40 MHz sampling clock. At the output of the AD9040A, output data reflects an interleaved alias of the input pulse. The repetitive sampling allows the measurement of ADC transient response as shown in performance graphs elsewhere in this data sheet.

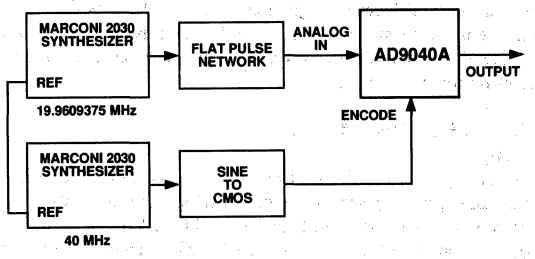

Figure 6. AD9040A Transient Response Test

Layout Information

Preserving the accuracy and dynamic performance of the AD9040A requires that designers pay special attention to the layout of the printed circuit board.

Analog paths should be kept as short as possible and be properly terminated to avoid reflections. The analog input and reference voltage connections should be kept away from digital signal paths; this reduces the amount of digital switching noise which is capacitively coupled into the analog section. Digital signal paths should also be kept short, and run lengths should be matched to avoid propagation delay mismatch. The AD9040A digital outputs should be buffered or latched close to the device (<2 cm). This prevents load transients which may feedback into the device.

In high speed circuits, layout of the ground is critical. A single, low impedance ground plane on the component side of the board is recommended. Power supplies should be capacitively coupled to the ground plane with high quality chip capacitors to reduce noise in the circuit. Multilayer boards allow designers to lay out signal traces without interrupting the ground plane, and provide low impedance ground planes. In systems with dedicated analog and digital grounds, all grounds of the AD9040A should be connected to the analog ground plane.

The power supplies of the AD9040A should be isolated from the supplies used for external devices; this reduces the amount of noise coupled into the ADC. The digital +5 volt connection of the device (V_D, Pin 23) powers the digital outputs and should be connected to the same supply as $+V_S$ (Pins 3 and 10). Connecting V_D to a system digital supply may couple noise into the device. Sockets limit dynamic performance and are not recommended for use with the AD9040A.

AD9040A EVALUATION BOARD

The evaluation board for the AD9040A (AD9040A/PCB) provides an easy and flexible method for evaluating the ADC's performance without (or prior to) developing a user-specific printed circuit board. The two-sided board includes a reconstruction DAC and digital output interface, and uses the layout and applications suggestions outlined above. It is available from Analog Devices at nominal cost.

Generous space is provided near the analog input and digital outputs to support additional signal processing components the user may wish to add. This prototyping area includes through holes with 100-mil centers to support a variety of component additions.

Input/Output/Supply Information

Power supply, analog input, clock connections, and reconstructed output (RC OUTPUT) are identified by labels on the evaluation board. Operation of the evaluation board should conform to the following characteristics:

Table I. Evaluation Board Characteristics

Parameter	Typical	Units
Supply Current		
+5 V	250	mA
−5.2 V	300	mA
A_{IN}		
Impedance	51	Ω
Voltage Range	±1.0	V
CLOCK		
Impedance	51	Ω
Frequency	40	Msps
RC OUTPUT		
Impedance	51	Ω
Voltage Range	0 to −1 V	V

Analog Input

Analog input signals can be fed directly into the Device Under Test input (A_{IN}). The A_{IN} input is terminated at the device with a 51 Ω resistor.

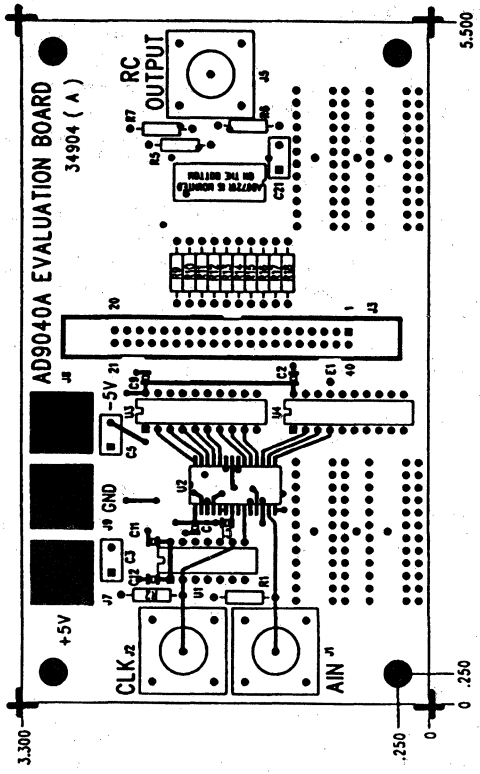

Figure 7. AD9040A/PCB Top View

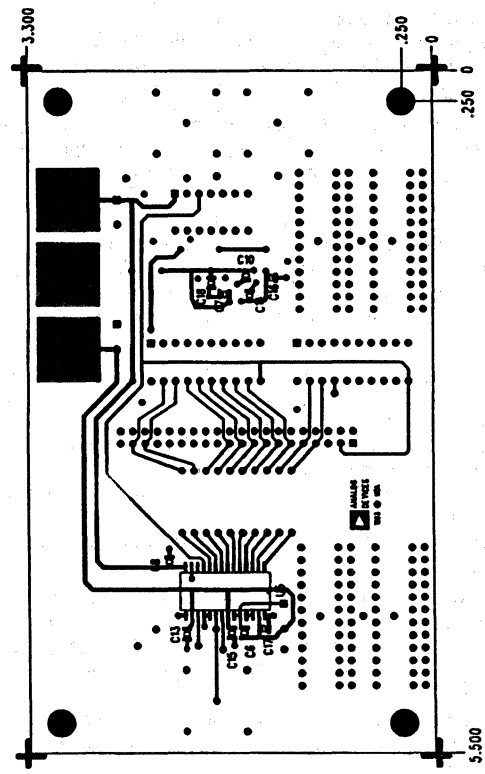

Figure 8. AD9040A/PCB Bottom View

DAC Reconstruction

The AD9040A evaluation board provides an on-board AD9721 reconstruction DAC for observing the digitized analog input signal. The AD9721 is terminated into 51 ohms to provide a 1 V p-p signal at the output (RC OUTPUT).

Output Data

The output data bits are latched with a CMOS 74AC574 which drives a 40-pin connector (AMP p/n 102153-9). The data and clock signals are available on the connector per the pin assignments shown on the schematic of the evaluation board. Output data are available on the falling edge of the clock.

Table II. AD9040A Digital Coding

Analog Input	Voltage Level	Out-of-Range	Digital Output

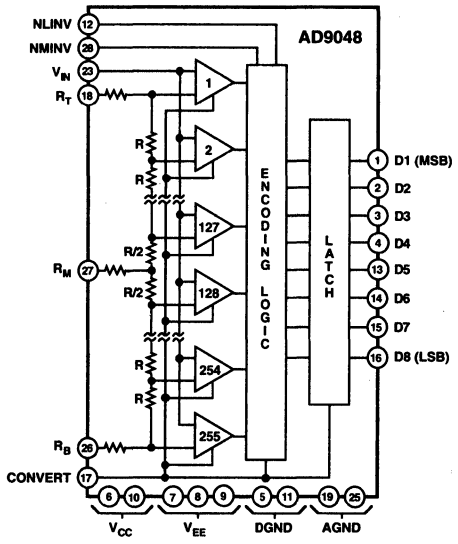
Monolithic 8-Bit Video A/D Converter

AD9048

FEATURES
35MSPS Encode Rate
16pF Input Capacitance
550mW Power Dissipation
Industry-Standard Pinouts
MIL-STD-883 Compliant Versions Available

APPLICATIONS
Professional Video Systems
Special Effects Generators
Electro-Optics
Digital Radio
Electronic Warfare (ECM, ECCM, ESM)

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9048 is an 8-bit, 35MSPS flash converter, made on a high speed bipolar process, which is an alternate source for the TDC1048 unit but offers enhancements over its predecessor. Lower power dissipation makes the AD9048 attractive for a variety of system designs.

Because of its wide bandwidth, it is an ideal choice for real-time conversion of video signals. Input bandwidth is flat with no missing codes.

Clocked latching comparators, encoding logic and output buffer registers operating at minimum rates of 35MSPS preclude a need for a sample-and-hold (S/H) or track-and-hold (T/H) in most system designs using the AD9048. All digital control inputs and outputs are TTL compatible.

Devices operating over two ambient temperature ranges and with two grades of linearity are available. Linearities of either 0.5LSB or 0.75LSB can be ordered for a commercial range of 0 to +70°C, or extended case temperatures of −55°C to +125°C. Commercial versions are packaged in 28-pin DIPs; extended temperature versions are available in ceramic DIP and ceramic LCC packages. Both commercial units and MIL-STD-883 units are standard products.

The AD9048 A/D converter is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD9048/883B data sheet for detailed specifications.

NOTES

[1]Maximum ratings are limiting values, to be applied individually, and beyond which the serviceability of the device may be impaired. Functional operation under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods of time may affect device reliability.

[2]Applied voltage must be current-limited to specified range.

[3]Forcing voltage must be limited to specified range.

[4]Current is specified as negative when flowing into the device.

[5]Output High; one pin to ground; one second duration.

[6]Typical thermal impedances (no air flow) are as follows:
Ceramic DIP: $\theta_{JA} = 49°C/W$; $\theta_{JC} = 15°C/W$ LCC: $\theta_{JA} = 69°C/W$; $\theta_{JC} = 21°C/W$
JLCC: $\theta_{JA} = 59°C/W$; $\theta_{JC} = 19°C/W$
To calculate junction temperature (T_J), use power dissipation (PD) and thermal impedance:
$T_J = PD(\theta_{JA}) + T_{AMBIENT} = PD(\theta_{JC}) = + T_{CASE}$

[7]Measured with V_{IN} = 0V and CONVERT low (sampling mode).

[8]Determined by beat frequency testing for no missing codes.

[9]$V_{RT} \geq V_{RB}$ under all circumstances.

[10]Outputs terminated with 40pF and 810Ω pull-up resistors.

[11]Interval from 50% point of leading edge CONVERT pulse to change in output data.

[12]For full scale step input, 8-bit accuracy attained in specified time.

[13]Recovers to 8-bit accuracy in specified time after −3V input overvoltage.

[14]Output time skew includes high-to-low and low-to-high transitions as well as bit-to-bit time skew differences.

[15]Measured at 20MHz encode rate with analog input 1dB below full scale.

[16]Measured at 35MHz encode rate with analog input 1dB below full scale.

[17]RMS signal to rms noise.

[18]Peak signal to rms noise.

[19]DC to 8MHz noise bandwidth with 1.248MHz slot; four sigma loading; 20MHz encode.

[20]Clock frequency = 4 × NTSC = 14.32MHz. Measured with 40-IRE modulated ramp.

Specifications subject to change without notice.

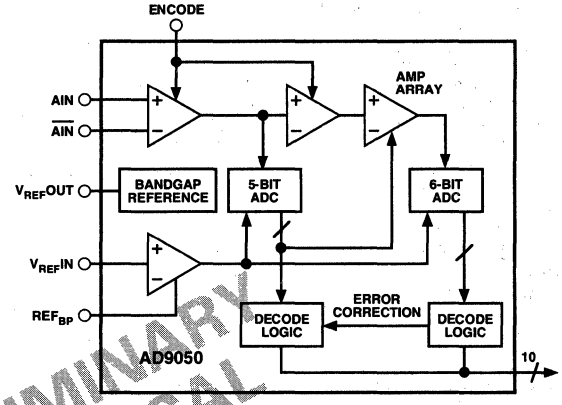
FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9050 is a complete 10-bit monolithic sampling analog-to-digital converter (ADC) with on-board track-and-hold and reference. The unit is designed for low cost, high performance applications and requires only +5 V and an encode clock to achieve 40 Msps sample rates with 10-bit resolution.

The encode clock is TTL compatible and the digital outputs are 5 V/3 V, selected by the user. The two-step architecture used in the AD9050 is optimized to provide the best dynamic performance available while maintaining low power requirements.

The 2.5 V reference is included on-board, or the user can provide an external reference voltage for gain control, or matching of multiple devices. Fabricated on an advanced BiCMOS process, the AD9050 is packaged in space saving surface mount packages and will be specified over the commercial (0°C to +85°C) temperature range.

PIN CONNECTIONS

AD9050JR ..... 0°C to +85°C
Storage Temperature ..... –65°C to +150°C

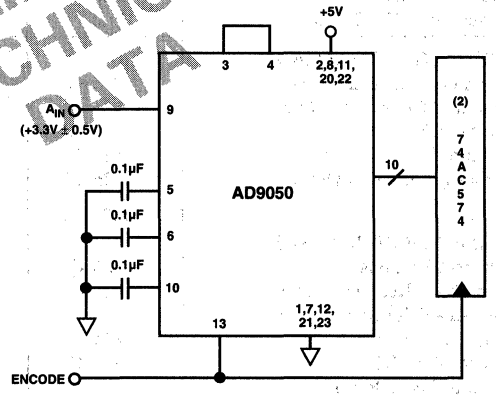

Figure 1. Typical Connections

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD9050 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

Dual 8-Bit 50 MSPS A/D Converter

AD9058

FEATURES
Two Matched ADCs on Single Chip
50 MSPS Conversion Speed
On-Board Voltage Reference
Low Power (<1W)
Low Input Capacitance (10 pF)
±5 V Power Supplies
Flexible Input Range

APPLICATIONS
Quadrature Demodulation for Communications
Digital Oscilloscopes
Electronic Warfare
Radar

GENERAL DESCRIPTION

The AD9058 combines two independent high performance 8-bit analog-to-digital converters (ADCs) on a single monolithic IC. Combined with an optional on-board voltage reference, the AD9058 provides a cost effective alternative for systems requiring two or more ADCs.

Dynamic performance (SNR, ENOB) is optimized to provide up to 50 MSPS conversion rates. The unique architecture results in low input capacitance while maintaining high performance and low power (<0.5 watt/channel). Digital inputs and outputs are TTL compatible.

Performance has been optimized for an analog input of 2 V p-p (±1 V; 0 to +2 V). Using the on-board +2 V voltage reference, the AD9058 can be set up for unipolar positive operation (0 to +2 V). This internal voltage reference can drive both ADCs.

Commercial (0°C to +70°C) and military (−55°C to +125°C) temperature range parts are available. Parts are supplied in hermetic 48-pin DIP and 44-pin "J" lead packages.

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]For applications in which $+V_S$ may be applied before $-V_S$, or $+V_S$ current is not limited to 500 mA, a reverse biased clamping diode should be inserted between ground and $-V_S$ to prevent destructive latch up. See section entitled "Using the AD9058."

[3]Typical thermal impedances: 44-pin hermetic J-Leaded ceramic package: θ_{JA} = 86.4°C/W; θ_{JC} = 24.9°C/W; 48-pin hermetic DIP θ_{JA} = 40°C/W; θ_{JC} = 12°C/W.

[4]To achieve guaranteed conversion rate, connect each data output to ground through a 2 kΩ pull-down resistor.

[5]SNR performance limits for the 48-pin DIP "D" package are 1 dB less than shown. ENOB limits are degraded by 0.3 dB. SNR and ENOB measured with analog input signal 1 dB below full scale at specified frequency.

[6]Crosstalk rejection measured with full-scale signals of different frequencies (2.3 MHz and 3.5 MHz) applied to each channel. With both signals synchronously encoded at 40 MSPS, isolation of the undesired frequency is measured with an FFT.

[7]Applies to both A/Ds and includes internal ladder dissipation.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.

II – 100% production tested at +25°C, and sample tested at specified temperatures.

III – Sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

FEATURES
Monolithic 10-Bit/75 MSPS Converter
ECL Outputs
Bipolar (±1.75 V) Analog Input
57 dB SNR @ 2.3 MHz Input
Low (45 pF) Input Capacitance
MIL-STD-883 Compliant Versions Available

APPLICATIONS
Digital Oscilloscopes
Medical Imaging
Professional Video
Radar Warning/Guidance Systems
Infrared Systems

GENERAL DESCRIPTION

The AD9060 A/D converter is a 10-bit monolithic converter capable of word rates of 75 MSPS and above. Innovative architecture using 512 input comparators instead of the traditional 1024 required by other flash converters reduces input capacitance and improves linearity.

Inputs and outputs are ECL-compatible, which makes the AD9060 the recommended choice for systems with conversion rates >30 MSPS, to minimize system noise. An overflow bit is provided to indicate analog input signals greater than $+V_{SENSE}$.

Voltage sense lines are provided to insure accurate driving of the $\pm V_{REF}$ voltages applied to the units. Quarter-point taps on the resistor ladder help optimize the integral linearity of the unit.

Either 68-pin ceramic leaded (gull wing) packages or ceramic LCCs are available and are specifically designed for low thermal impedances. Two performance grades for temperatures of both 0 to +70°C and −55°C to +125°C ranges are offered to allow the user to select the linearity best suited for each application. Dynamic performance is fully characterized and production tested at +25°C. MIL-STD-883 units are available.

The AD9060 A/D converter is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD9060/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]Typical thermal impedances (part soldered onto board): 68-pin leaded ceramic chip carrier: θ_{JC} = 1°C/W; θ_{JA} = 17°C/W (no air flow); θ_{JA} = 15°C/W (air flow = 500 LFM). 68-pin ceramic LCC: θ_{JC} = 2.6°C/W; θ_{JA} = 15°C/W (no air flow); θ_{JA} = 13°C/W (air flow = 500 LFM).

[3]$3/4_{REF}$, $1/2_{REF}$, and $1/4_{REF}$ reference ladder taps are driven from dc sources at +0.875 V, 0 V, and −0.875 V, respectively. Outputs terminated through 100 Ω to −2.0 V; C_L < 4 pF. Accuracy of the overflow comparator is not tested and not included in linearity specifications.

[4]Measured with ANALOG IN = $+V_{SENSE}$.

[5]Output delay measured as worst-case time from 50% point of the rising edge of ENCODE to 50% point of the slowest rising or falling edge of D_0–D_9. Output skew measured as worst-case difference in output delay among D_0–D_9.

[6]RMS signal to rms noise with analog input signal 1 dB below full scale at specified frequency.

[7]Intermodulation measured with analog input frequencies of 2.3 MHz and 3.0 MHz at 7 dB below full scale.

[8]Measured as the ratio of the worst-case change in transition voltage of a single comparator for a 5% change in $+V_S$ or $-V_S$.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.

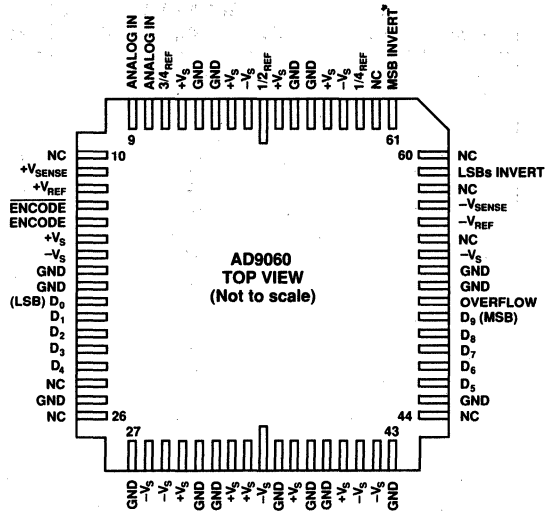
II – 100% production tested at +25°C, and sample tested at specified temperatures.

III – Sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.



AD9060 Pin Designations

AD9060 PIN DESCRIPTIONS

Pin No.	Name	Function
1	$1/2_{REF}$	Midpoint of internal reference ladder.
2, 16, 28, 29, 35, 41, 42, 54, 64	$-V_S$	Negative supply voltage; nominally −5.2 V ±5%.
3, 6, 15, 30, 33, 34, 37, 40, 65, 68	$+V_S$	Positive supply voltage; nominally +5 V ±5%.
4, 5, 17, 18, 25, 27, 31, 32, 36, 38, 39, 43, 45, 52, 53, 66, 67	GROUND	All ground pins should be connected together and to low-impedance ground plane.
7	$3/4_{REF}$	Three-quarter point of internal reference ladder.
8, 9	ANALOG IN	Analog input; nominally between ±1.75 V.
11	$+V_{SENSE}$	Voltage sense line to most positive point on internal resistor ladder. Normally +1.75 V.
12	$+V_{REF}$	Voltage force connection for top of internal reference ladder. Normally driven to provide +1.75 V at $+V_{SENSE}$.
13	$\overline{\text{ENCODE}}$	Differential ECL convert signal which starts digitizing process.
14	ENCODE	ECL-compatible convert command used to begin digitizing process.
19–23, 46–50	D_0–D_9	ECL-compatible digital output data.
51	OVERFLOW	ECL-compatible output indicating ANALOG IN > $+V_{SENSE}$.
56	$-V_{REF}$	Voltage force connection for bottom of internal reference ladder. Normally driven to provide −1.75 V at $-V_{SENSE}$.
57	$-V_{SENSE}$	Voltage sense line to most negative point on internal resistor ladder. Normally −1.75 V.
59	LSBs INVERT	Normally grounded. When connected to $+V_S$, lower order bits (D_0–D_8) are inverted. Not ECL-compatible.
61	MSB INVERT	Normally grounded. When connected to $+V_S$, most significant bit (MSB; D_9) is inverted. Not ECL-compatible.
63	$1/4_{REF}$	One-quarter point of internal reference ladder.

[1]This column lists the data format for the bus with "µP" indicating microprocessor capability—i.e., for a 12-bit converter 8/12, µP indicates that the data can be formatted for an 8-bit bus or can be in parallel (12 bits) and is microprocessor compatible.

[2]Ext indicates external reference with the range of voltages listed where applicable. Ext (M) indicates external reference with multiplying capability. Int indicates reference is internal. A voltage value is given if the reference is pinned out.

[3]Package Options: D = Hermetic DIP, Ceramic or Metal; E = Ceramic Leadless Chip Carrier; F = Ceramic Flatpack; G = Ceramic Pin Grid Array; H = Hermetic Metal Can; J = J-Leaded Ceramic Package; M = Hermetic Metal Can DIP; N = Plastic or Epoxy Sealed DIP; P = Plastic Leaded Chip Carrier; Q = Cerdip; R = Small Outline "SOIC" Package; RS = SSOP—Shrink Small Outline Package; S = Plastic Quad Flatpack; ST = Thin Quad Flatpack; T = TO-92; U = TSOP—Thin Small Outline Package; W = Nonhermetic Ceramic/Glass DIP; Y = Single-In-Line "SIP" Package; Z = Ceramic Leaded Chip Carrier.

[4]Temperature Ranges: C = Commercial, 0°C to +70°C; I = Industrial, –40°C to +85°C (Some older products –25°C to +85°C); M = Military, –55°C to +125°C. If a device has military grade offerings, the M temperature designator will be followed by: / to indicate 883B, $_J$ for JAN, $_D$ for SMD, and $_S$ for space level.

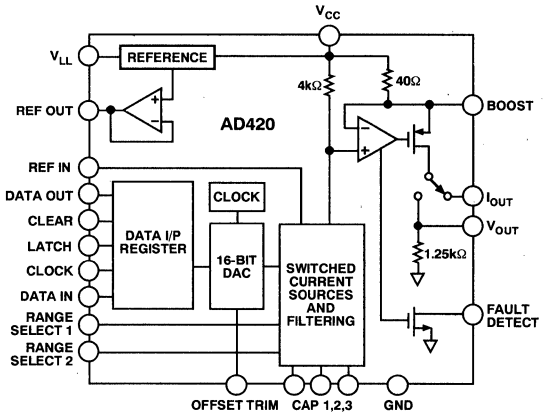
Serial Input 16-Bit 4–20 mA, 0–20 mA DAC

AD420

FEATURES

4–20 mA, 0–20 mA or 0–24 mA Current Output
16-Bit Resolution and Monotonicity
±0.012% max Integral Nonlinearity
±0.05% max Offset (Trimmable)
±0.15% max Total Output Error (Trimmable)
Flexible Serial Digital Interface (3.3 Mbps)
On-Chip Loop Fault Detection
On-Chip 5 V Reference (25 ppm/°C max)
Asynchronous CLEAR Function
Power Supply Range of 12 V–36 V
Output Loop Compliance of 0 V–33.5 V
24-Pin SOIC and PDIP Packages

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD420 is a complete digital to current loop output converter, designed to meet the needs of the industrial control market. It provides a high precision, fully integrated, low cost single-chip solution for generating current loop signals, in a compact 24-pin SOIC or PDIP package.

The output current range can be programmed to 4–20 mA, 0–20 mA or an overrange function of 0–24 mA. The AD420 can alternatively provide a voltage output from a separate pin that can be configured to provide 0 V–5 V, 0 V–10 V, ±5 V or ±10 V with the addition of a single external buffer amplifier.

The 3.3M Baud serial input logic design minimizes the cost of galvanic isolation and allows for simple connection to commonly used microprocessors. It can be used in three-wire or asynchronous mode and a serial-out pin is provided to allow daisy chaining of multiple DACs on the current loop side of the isolation barrier.

The AD420 uses sigma-delta (ΣΔ) DAC technology to achieve 16-bit monotonicity at very low cost. Full-scale settling to 0.1% occurs within 3 ms. The only external components that are required (in addition to normal transient protection circuitry) are three low cost capacitors which are used in the DAC output filter.

If the AD420 is going to be used at extreme temperatures and supply voltages, an external output transistor can be used to minimize power dissipation on the chip via the "BOOST" pin.

The FAULT DETECT pin signals when an open circuit occurs in the loop. The on-chip voltage reference can be used to supply a precision +5 V to external components in addition to the AD420 or, if the user desires temperature stability exceeding 25 ppm/°C, an external precision reference such as the AD586 can be used as the reference.

The AD420 is available in a 24-pin SOIC and PDIP over the industrial temperature range of −40°C to +85°C.

PRODUCT HIGHLIGHTS

1. The AD420 is a single chip solution for generating 4–20 mA or 0–20 mA signals at the "controller end" of the current loop.
2. The AD420 operates on +12 V to +36 V supplies, with an output loop compliance of 0 V to V_{CC} – 2.5 V.
3. The flexible serial input can be used in Three-Wire Mode with SPI* or MICROWIRE† microcontrollers, or in Asynchronous Mode which minimizes the number of control signals required.
4. The Serial Data Out pin can be used to daisy chain any number of AD420s together in Three-Wire Mode.
5. At Power-Up the AD420 initializes its output to the low end of the selected range.
6. The AD420 has an asynchronous CLEAR pin which sends the output to the low end of the selected range (0 mA, 4 mA, or 0 V).
7. The AD420 BOOST pin accommodates an external transistor to off-load power dissipation from the chip.
8. The offset of ±0.05% and total output error of ±0.15% can be trimmed if desired, using two external potentiometers.

NOTES

[1]Total Output Error includes Offset and Gain Error. Total Output Error and Offset Error are with respect to the Full-Scale Output and are measured with an ideal +5 V reference. If the internal reference is used, the reference errors must be added to the Offset and Total Output Errors.

[2]PSRR is measured by varying V_{CC} from 12 V to 36 V.

[3]When V_{CC} is greater than 32 V the Minimum R_L is 200 Ω.

[4]External capacitor selection must be as described in Figure 5.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

V_{CC} to GND . . . . . 36 V
IOUT to GND . . . . . V_{CC}
Digital Inputs to GND . . . . . −0.5 V to +7 V
Digital Outputs to GND . . . . . −0.5 V to V_{LL} + 0.3 V
V_{LL} and REFOUT: Outputs safe for indefinite short to ground.
Storage Temperature . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 sec) . . . . . +300°C
Thermal Impedance:
SOIC (R) Package . . . . . θ_{JA} = 75°C/W
PDIP (N) Package . . . . . θ_{JA} = 50°C/W

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions above those indicated in the operational specification is not implied. Exposure to absolute maximum specifications for extended periods may affect device reliability.

ORDERING GUIDE

X	0	1	4–20 mA Range
X	1	0	0–20 mA Range
X	1	1	0–24 mA Range

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD420 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

Data Setup Time (Critical Clock Edge)	t_{ADS}	50	ns min
Data Hold Time (Critical Clock Edge)	t_{ADH}	20	ns min
Clear Pulse Width	t_{CLR}	50	ns min

ASYNCHRONOUS INTERFACE

Note in the timing diagram for Asynchronous Mode operation each data word is "framed" by a START (0) bit and a STOP (1) bit. The data timing is with respect to the rising edge of the CLOCK at the center of each bit cell. Bit cells are 16 clocks long, and the first cell (the START bit) begins at the first clock following the leading (falling) edge of the START bit. Thus the MSB (D15) is sampled 24 clock cycles after the beginning of the START bit, D14 is sampled at clock number 40, and so on. During any "dead time" before writing the next word the DATA IN pin must remain at logic 1.

The DAC output updates when the STOP bit is received. In the case of a "framing error" (the STOP bit sampled as a 0) the AD420 will output a pulse at the DATA OUT pin one clock period wide during the clock period subsequent to sampling the STOP bit. The DAC output will not update if a "framing error" is detected.

PIN DESCRIPTION

Pin #	Symbol	Type	Function
2	V_{LL}	P	Auxiliary buffered +4.5 V digital logic voltage. This pin is the internal supply voltage for the digital circuitry and can be used as a termination for pull-up resistors. An external +5 V power supply can be connected to V_{LL}. It will override this buffered voltage, thus reducing the internal power dissipation.
3	FAULT DETECT	DO	FAULT DETECT, connected to a pull-up resistor, is asserted low when the output current does not match the DAC's programmed value. For example, in case the current loop is broken.
4 5	RANGE SELECT 2 RANGE SELECT 1	DI	Selects the converters output operating range. One output voltage range and three output current ranges are available.
6	CLEAR	DI	Valid V_{IH} will unconditionally force the output to go to the minimum of its programmed range. After CLEAR is removed the DAC output will remain at this value. The data in the input register is unaffected.
7	LATCH	DI	In the three-wire interface mode a rising edge parallel loads the serial input register data into the DAC. To use the asynchronous mode connect LATCH through a current limiting resistor to V_{CC}.
8	CLOCK	DI	Data Clock Input. The clock period is equal to the input data bit rate in the three-wire interface mode and is 16 times the bit rate in asynchronous mode.
9	DATA IN	DI	Serial Data Input.
10	DATA OUT	DO	Serial Data Output. In the three-wire interface mode, this output can be used for daisy chaining multiple AD420s. In the asynchronous mode a positive pulse will indicate a framing error after the stop-bit is received.
11	GND	P	Ground (Common).
14	REF OUT	AO	+5 V Reference Output.
15	REF IN	AI	Reference Input.
16	OFFSET TRIM	AI	Offset Adjust.
17	V_{OUT}	AO	Voltage Output.
18	I_{OUT}	AO	Current Output.
19	BOOST	AO	Connect to an external transistor to reduce the power dissipated in the AD420 output transistor, if desired.
20 21 22	CAP 1 CAP 2 CAP 3	AI	These pins are used for internal filtering. Connect capacitors between each of these pins and V_{CC}. Refer to the description of current output operation.
23	V_{CC}	P	+12 V to +36 V Power.
1, 12, 13, 24	NC		No Connection. No internal connections inside device.

Type: AI = Analog Input, AO = Analog Output, DI = Digital Input, DO = Digital Output, P = Power

DEFINITIONS OF SPECIFICATIONS

RESOLUTION: For 16-bit resolution, 1 LSB = 0.0015% of the FSR. In the 4–20 mA range 1 LSB = 244 nA.

INTEGRAL NONLINEARITY: Analog Devices defines integral nonlinearity as the maximum deviation of the actual, adjusted DAC output from the ideal analog output (a straight line drawn from 0 to FS−1 LSB) for any bit combination. This is also referred to as relative accuracy.

DIFFERENTIAL NONLINEARITY: Differential nonlinearity is the measure of the change in the analog output, normalized to full scale, associated with an LSB change in the digital input code. Monotonic behavior requires that the differential linearity error be greater than −1 LSB over the temperature range of interest.

MONOTONICITY: A DAC is monotonic if the output either increases or remains constant for increasing digital inputs with the result that the output will always be a single-valued function of the input.

GAIN ERROR: Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been adjusted out.

OFFSET ERROR: Offset error is the deviation of the output current from its ideal value expressed as a percentage of the full-scale output with all 0s loaded in the DAC.

DRIFT: Drift is the change in a parameter (such as gain and offset) over a specified temperature range. The drift temperature coefficient, specified in ppm/°C, is calculated by measuring the parameter at T_{MIN}, 25°C, and T_{MAX} and dividing the change in the parameter by the corresponding temperature change.

CURRENT LOOP VOLTAGE COMPLIANCE: The voltage compliance is the maximum voltage at the IOUT pin for which the output current will be equal to the programmed value.

THEORY OF OPERATION

The AD420 uses a sigma-delta (ΣΔ) architecture to carry out the digital-to-analog conversion. This architecture is particularly well suited for the relatively low bandwidth requirements of the industrial control environment because of its inherent monotonicity at high resolution.

In the AD420 a second order modulator is used to keep complexity and die size to a minimum. The single bit stream from the modulator controls a switched current source that is then filtered by three, continuous time resistor-capacitor sections. The capacitors are the only external components that have to be added for standard current-out operation. The filtered current is amplified and mirrored to the supply rail so that the application simply sees a 4–20 mA, 0–20 mA, or 0–24 mA current source output with respect to ground. The AD420 is manufactured on a BiCMOS process that is well suited to implementing low voltage digital logic with high performance and high voltage analog circuitry.

The AD420 can also provide a voltage output instead of a current loop output if desired. The addition of a single external amplifier allows the user to obtain 0 V–5 V, 0 V–10 V, ±5 V, or ±10 V.

The AD420 has a loop fault detection circuit that warns if the voltage at IOUT attempts to rise above the compliance range, due to an open loop circuit or insufficient power supply voltage. The FAULT DETECT is an active low open drain signal so that one can connect several AD420s together to one pull-up resistor for global error detection. The pull-up resistor can be tied to the VLL pin, or an external +5 V logic supply.

The IOUT current is controlled by a PMOS transistor and internal amplifier as shown in the functional block diagram. The internal circuitry that develops the fault output avoids using a comparator with "window limits" since this would require an actual output error before the FAULT DETECT output becomes active. Instead, the signal is generated when the internal amplifier in the output stage of the AD420 has less than approximately one volt remaining of drive capability (when the gate of the output PMOS transistor nearly reaches ground). Thus the FAULT DETECT output activates slightly before the compliance limit is reached. Since the comparison is made within the feedback loop of the output amplifier, the output accuracy is maintained by its open loop gain, and no output error occurs before the fault detect output becomes active.

The three-wire digital interface, comprising DATA IN, CLOCK, and LATCH, interfaces to all commonly used serial microprocessors without the addition of any external glue logic. Data is loaded into an input register under control of CLOCK and is loaded to the DAC when LATCH is strobed. If a user wants to minimize the number of galvanic isolators in an intrinsically safe application, the AD420 can be configured to run in "asynchronous" mode. This mode is selected by connecting the LATCH pin to V_{CC} through a current limiting resistor. The data must then be combined with a start and stop bit to "frame" the information and trigger the internal LATCH signal.

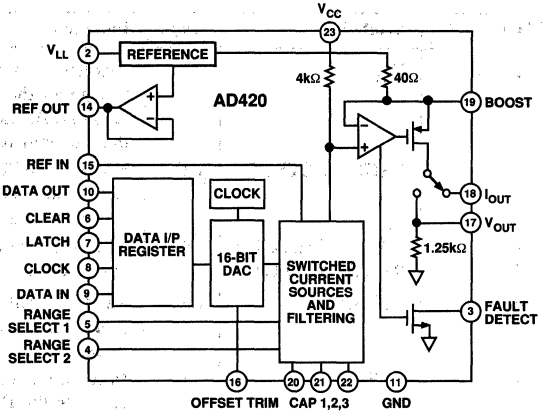

Figure 4. Functional Block Diagram

APPLICATIONS

CURRENT OUTPUT

The AD420 can provide 4–20 mA, 0–20 mA, or 0–24 mA output without any active external components. The three capacitors shown in Figure 5 are all that is required. These can be any type of low cost ceramic capacitors. To meet the specified full-scale settling time of 3 ms, low dielectric absorption capacitors (NPO) are required. Suitable values are C1 = 0.01 μF, C2 = 0.01 μF, and C3 = 0.0033 μF.

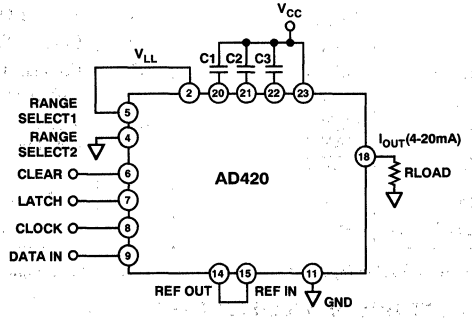

Figure 5. Standard Configuration

DRIVING INDUCTIVE LOADS

When driving inductive or poorly defined loads connect a 0.01 μF capacitor between IOUT (Pin 18) and GND (Pin 11). This will ensure stability of the AD420 with loads beyond 50 mH. There is no maximum capacitance limit. The capacitive component of the load may cause slower settling, though this may be masked by the settling time of the AD420. A programmed change in the current may cause a back EMF voltage on the output that may exceed the compliance of the AD420. To prevent this voltage from exceeding the supply rails connect protective diodes between IOUT and each of V_{CC} and GND.

VOLTAGE-MODE OUTPUT

Since the AD420 is a single supply device, it is necessary to add an external buffer amplifier to the VOUT pin to obtain a selection of high quality bipolar output voltage ranges as shown in Figure 6.

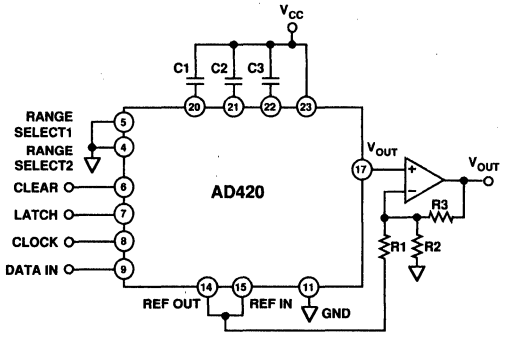

Figure 6.

Table IV. Buffer Amplifier Configuration

R1	R2	R3	VOUT
Open	Open	0	0–5 V
Open	R	R	0–10 V
R	Open	R	±5 V
R	2R	2R	±10 V

Suitable R = 5 kΩ.

OPTIONAL SPAN AND ZERO TRIM

For those users who would like lower than specified values of offset and gain error, Figure 7 shows a simple way to trim these parameters. Care should be taken to select low drift resistors because they will affect the temperature drift performance of the DAC.

The adjustment algorithm is iterative. The procedure for trimming the AD420 in the 4–20 mA mode can be accomplished as follows:

STEP I . . .OFFSET ADJUST
Load all zeros. Adjust RZERO for 4.00000 mA of output current.

STEP II . . .GAIN ADJUST
Load all ones. Adjust RSPAN for 19.99976 mA (FS − 1 LSB) of output current.
Return to STEP I and iterate until convergence is obtained.

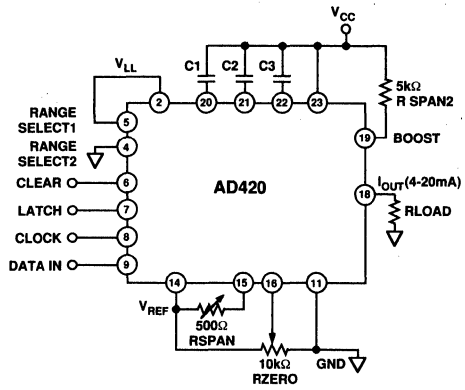

Figure 7. Offset and Gain Adjust

THREE-WIRE INTERFACE

Figure 8 shows the AD420 connected in the three-wire interface mode. The AD420 data input block contains a serial input shift register and a parallel latch. The contents of the shift register are controlled by the DATA IN signal and the rising edges of the CLOCK. Upon request of the LATCH pin the DAC and internal latch are updated from the shift register parallel outputs. The CLOCK should remain inactive while the DAC is updated. Refer to the timing requirements for Three-Wire Interface.

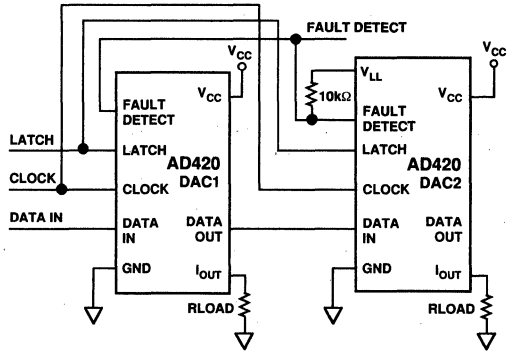

Figure 8. Three-Wire Interface Using Multiple DACs with Joint Fault Detect

USING MULTIPLE DACS WITH FAULT DETECT

The three-wire interface mode can utilize the serial DATA OUT for easy interface to multiple DACs. To program the two AD420s in Figure 8, 32 data bits are required. The first 16 bits are clocked into the input shift register of DAC1. The next 16 bits transmitted pass the first 16 bits from the DATA OUT pin of DAC1 to the input register of DAC2. The input shift registers of the two DACs operate as a single 32-bit shift register, with the leading 16 bits representing information for DAC2 and the trailing 16 bits serving for DAC1. Each DAC is then updated upon request of the LATCH pin. The daisy-chain can be extended to as many DACs as required.

ASYNCHRONOUS INTERFACE USING OPTO-COUPLERS

The AD420 connected in ASYNCHRONOUS INTERFACE mode with opto-couplers is shown in Figure 9. Asynchronous operation minimizes the number of control signals required for isolation of the digital system from the control loop. The resistor connected between the LATCH pin and V_{CC} is required to activate this mode. For operation with V_{CC} below 18 V use a 50 kΩ pull-up resistor, from 18 V–36 V use 100 kΩ. Asynchronous mode requires that the clock run at 16 times the data bit rate, therefore to operate at the maximum input data rate of 150 kbps an input clock of 2.4 MHz is required. The actual data rate achieved may be limited by the type of opto-couplers chosen. The number of control signals can further be reduced by creating the appropriate clock signal on the current loop side of the isolation barrier.

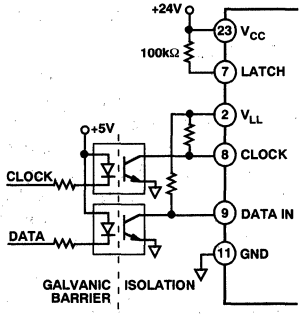

Figure 9. Asynchronous Interface Using Opto-Couplers

MICROPROCESSOR INTERFACE SECTION

AD420 TO MC68HC11 (SPI BUS) INTERFACE

The AD420 interface to the Motorola SPI (Serial Peripheral Interface) is shown in Figure 10. The MOSI, SCK, and $\overline{SS}$ pins of the HC11 are respectively connected to the DATA IN, CLOCK, and LATCH pins of the AD420. The majority of the interfacing issues are done in the software initialization. A typical routine such as the one shown below begins by initializing the state of the various SPI data and control registers.

```
INIT    LDAA  #$2F     ;SS = 1; SCK = 0; MOSI = 1
        STAA  PORTD    ;SEND TO SPI OUTPUTS
        LDAA  #$38     ;SS, SCK,MOSI = OUTPUTS
        STAA  DDRD     ;SEND DATA DIRECTION INFO
        LDAA  #$50     ;DABL INTRPTS,SPI IS MASTER & ON
        STAA  SPCR     ;CPOL = 0, CPHA = 0, 1MHZ BAUDRATE
NEXTPT  LDAA  MSBY     ;LOAD ACCUM W/UPPER 8 BITS
        BSR   SENDAT   ;JUMP TO DAC OUTPUT ROUTINE
        JMP   NEXTPT   ;INFINITE LOOP
SENDAT  LDY   #$1000   ;POINT AT ON-CHIP REGISTERS
        BCLR  $08,Y,$20 ;DRIVE SS (LATCH) LOW
        STAA  SPDR     ;SEND MS-BYTE TO SPI DATA REG
WAIT1   LDAA  SPSR     ;CHECK STATUS OF SPIE
        BPL   WAIT1    ;POLL FOR END OF X-MISSION
        LDAA  LSBY     ;GET LOW 8 BITS FROM MEMORY
        STAA  SPDR     ;SEND LS-BYTE TO SPI DATA REG
WAIT2   LDAA  SPSR     ;CHECK STATUS OF SPIE
        BPL   WAIT2    ;POLL FOR END OF X-MISSION
        BSET  $08,Y,$20 ;DRIVE SS HIGH TO LATCH DATA
        RTS
```

The SPI data port is configured to process data in 8-bit bytes. The most significant data byte (MSBY) is retrieved from memory and processed by the SENDAT routine. The $\overline{SS}$ pin is driven low by indexing into the PORTD data register and clear Bit 5. The MSBY is then sent to the SPI data register where it is automatically transferred to the AD420 internal shift resister. The HC11 generates the requisite eight clock pulses with data valid on the rising edges. After the MSBY is transmitted, the least significant byte (LSBY) is loaded from memory and transmitted in a similar fashion. To complete the transfer, the LATCH pin is driven high when loading the complete 16-bit word into the AD420.

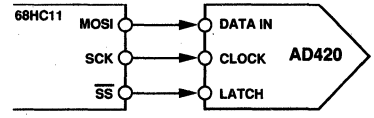

Figure 10. AD420 to 68HC11 (SPI) Interface

AD420 TO MICROWIRE INTERFACE

The flexible serial interface of the AD420 is also compatible with the National Semiconductor MICROWIRE interface. The MICROWIRE interface is used in micro controllers such as the COP400 and COP800 series of processors. A generic interface to use the MICROWIRE interface is shown in Figure 11. The G1, SK, and SO pins of the MICROWIRE interface are respectively connected to the LATCH, CLOCK, and DATA IN pins of the AD420.

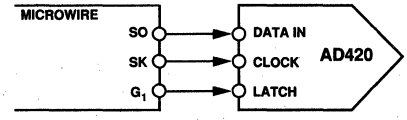

Figure 11. AD420 to MICROWIRE Interface

EXTERNAL BOOST FUNCTION

The external boost transistor reduces the power dissipated in the AD420 by reducing the current flowing in the on-chip output transistor (dividing it by the current gain of the external circuit). A discrete NPN transistor with a breakdown voltage BV_{CEO}, greater than 36 V can be used as shown in Figure 12.

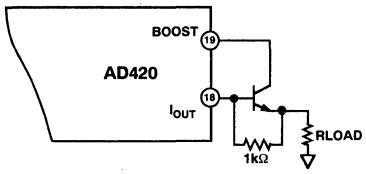

Figure 12. External Boost Configuration

The external boost capability has been developed for those users who may wish to use the AD420, in the SOIC package, at the extremes of the supply voltage, load current, and temperature range. The PDIP package (because of its lower thermal resistance) will operate safely over the entire specified voltage, temperature, and load current ranges without the boost transistor. The plot in Figure 13 shows the safe operating region for both package types. The boost transistor can also be used to reduce the amount of temperature induced drift in the part. This will minimize the temperature induced drift of the on-chip voltage reference, which improves drift and linearity.

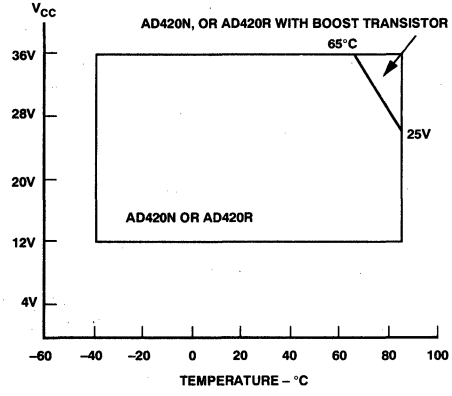

Figure 13. Safe Operating Region

AD420 PROTECTION

TRANSIENT VOLTAGE PROTECTION

The AD420 contains ESD protection diodes which prevent damage from normal handling. The industrial control environment can, however, subject I/O circuits to much higher transients. In order to protect the AD420 from excessively high voltage transients such as those specified in IEC 801, external power diodes and a surge current limiting resistor may be required, as shown in Figure 14. The constraint on the resistor is that during normal operation the output voltage level at IOUT must remain within its voltage compliance limit (IOUT × (Rp + R_{LOAD}) ≤ V_{CC} – 2.5 V) and the two protection diodes and resistor must have appropriate power ratings.

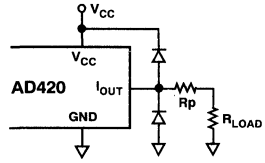

Figure 14. Output Transient Voltage Protection

BOARD LAYOUT AND GROUNDING

The AD420 ground pin, designated GND, is the "high quality" ground reference point for the device. Any external loads on the REF OUT and VOUT pins of the AD420 should be returned to this reference point. Analog and digital ground currents should not share a common path. Each signal should have an appropriate analog or digital signal return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths.

POWER SUPPLIES AND DECOUPLING

The AD420 supply pins, V_{CC} (Pin 23) and V_{LL} (Pin 2), should be decoupled to GND with 0.1 μF capacitors to eliminate high frequency noise that may otherwise get coupled into the analog system. High frequency ceramic capacitors are recommended. The decoupling capacitors should be located in close proximity to the pins and the ground line to have maximum effect.

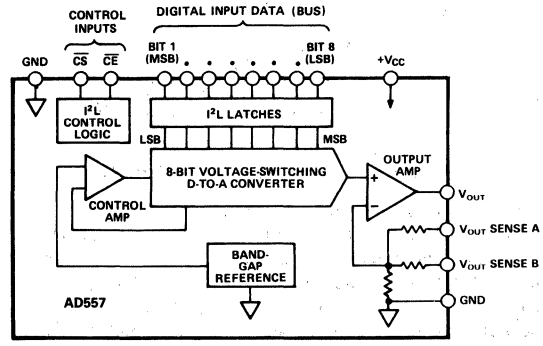
DACPORT Low Cost, Complete µP-Compatible 8-Bit DAC

AD557

FEATURES

Complete 8-Bit DAC
Voltage Output – 0 to 2.56V
Internal Precision Band-Gap Reference
Single-Supply Operation: +5V (±10%)
Full Microprocessor Interface
Fast: 1µs Voltage Settling to ±1/2LSB
Low Power: 75mW
No User Trims Required
Guaranteed Monotonic Over Temperature
All Errors Specified T_{min} to T_{max}
Small 16-Pin DIP or 20-Pin PLCC Package
Low Cost

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD557 DACPORT™ is a complete voltage-output 8-bit digital-to-analog converter, including output amplifier, full microprocessor interface and precision voltage reference on a single monolithic chip. No external components or trims are required to interface, with full accuracy, an 8-bit data bus to an analog system.

The low cost and versatility of the AD557 DACPORT are the result of continued development in monolithic bipolar technologies.

The complete microprocessor interface and control logic is implemented with integrated injection logic (I^2L), an extremely dense and low-power logic structure that is process-compatible with linear bipolar fabrication. The internal precision voltage reference is the patented low-voltage band-gap circuit which permits full-accuracy performance on a single +5V power supply. Thin-film silicon-chromium resistors provide the stability required for guaranteed monotonic operation over the entire operating temperature range, while laser-wafer trimming of these thin-film resistors permits absolute calibration at the factory to within ±2.5LSB; thus, no user-trims for gain or offset are required. A new circuit design provides voltage settling to ±1/2LSB for a full-scale step in 800ns.

The AD557 is available in two package configurations. The AD557JN is packaged in a 16-pin plastic, 0.3″-wide DIP. For surface mount applications, the AD557JP is packaged in a 20-pin JEDEC standard PLCC. Both versions are specified over the operating temperature range of 0 to +70°C.

PRODUCT HIGHLIGHTS

1. The 8-bit I^2L input register and fully microprocessor-compatible control logic allow the AD557 to be directly connected to 8- or 16-bit data buses and operated with standard control signals. The latch may be disabled for direct DAC interfacing.
2. The laser-trimmed on-chip SiCr thin-film resistors are calibrated for absolute accuracy and linearity at the factory. Therefore, no user trims are necessary for full rated accuracy over the operating temperature range.
3. The inclusion of a precision low-voltage band-gap reference eliminates the need to specify and apply a separate reference source.
4. The AD557 is designed and specified to operate from a single +4.5V to +5.5V power supply.
5. Low digital input currents, 100µA max, minimize bus loading. Input thresholds are TTL/low voltage CMOS compatible.
6. The single-chip, low power I^2L design of the AD557 is inherently more reliable than hybrid multichip or conventional single-chip bipolar designs.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Relative Accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the offset to the full scale of the device. See "Measuring Offset Error" on AD558 data sheet.

[2]Passive pull-down resistance is 2kΩ.

[3]Settling time is specified for a positive-going full-scale step to ± 1/2LSB. Negative-going steps to zero are slower, but can be improved with an external pull-down.

[4]The full-scale output voltage is 2.55V and is guaranteed with a + 5V supply.

[5]A monotonic converter has a maximum differential linearity error of ± 1LSB.

Specifications shown in **boldface** are tested on all production units at final electrical test.

Specifications subject to change without notice.

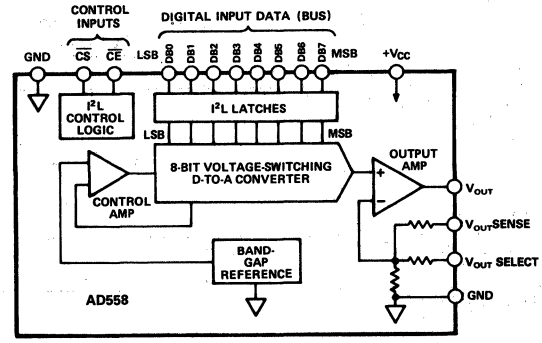
FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD558 DACPORT™ is a complete voltage-output 8-bit digital-to-analog converter, including output amplifier, full microprocessor interface and precision voltage reference on a single monolithic chip. No external components or trims are required to interface, with full accuracy, an 8-bit data bus to an analog system.

The performance and versatility of the DACPORT is a result of several recently-developed monolithic bipolar technologies. The complete microprocessor interface and control logic is implemented with integrated injection logic (I^2L), an extremely dense and low-power logic structure that is process-compatible with linear bipolar fabrication. The internal precision voltage reference is the patented low-voltage band-gap circuit which permits full-accuracy performance on a single +5V to +15V power supply. Thin-film silicon-chromium resistors provide the stability required for guaranteed monotonic operation over the entire operating temperature range (all grades), while recent advances in laser-wafer-trimming of these thin-film resistors permit absolute calibration at the factory to within ±1LSB; thus no user-trims for gain or offset are required. A new circuit design provides voltage settling to ±1/2LSB for a full-scale step in 800ns.

The AD558 is available in four performance grades. The AD558J and K are specified for use over the 0 to +70°C temperature range, while the AD558S and T grades are specified for −55°C to +125°C operation. The "J" and "K" grades are available either in 16-pin plastic (N) or hermetic ceramic (D) DIPS. They are also available in 20-pin JEDEC standard PLCC packages. The "S" and "T" grades are available in the 16-pin hermetic ceramic DIP package.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

PRODUCT HIGHLIGHTS

1. The 8-bit I^2L input register and fully microprocessor-compatible control logic allow the AD558 to be directly connected to 8- or 16-bit data buses and operated with standard control signals. The latch may be disabled for direct DAC interfacing.
2. The laser-trimmed on-chip SiCr thin-film resistors are calibrated for absolute accuracy and linearity at the factory. Therefore, no user trims are necessary for full rated accuracy over the operating temperature range.
3. The inclusion of a precision low-voltage band-gap reference eliminates the need to specify and apply a separate reference source.
4. The voltage-switching structure of the AD558 DAC section along with a high-speed output amplifier and laser-trimmed resistors give the user a choice of 0V to +2.56V or 0V to +10V output ranges, selectable by pin-strapping. Circuitry is internally compensated for minimum settling time on both ranges; typically settling to ±1/2LSB for a full-scale 2.55 volt step in 800ns.
5. The AD558 is designed and specified to operate from a single +4.5V to +16.5V power supply.
6. Low digital input currents, 100μA max, minimize bus loading. Input thresholds are TTL/low voltage CMOS compatible over the entire operating V_{CC} range.
7. All AD558 grades are available in chip form with guaranteed specifications from +25°C to T_{max}. MIL-STD-883, Class B visual inspection is standard on Analog Devices bipolar chips. Contact the factory for additional chip information.
8. The AD558 is available in versions compliant with MIL-STD-883. Refer to Analog Devices Military Products Databook or current AD588/883B data sheet for detailed specifications.

NOTES
[1]The AD558 S & T grades are available processed and screened to MIL-STD-883 Class B. Consult Analog Devices' Military Databook for details.
[2]Relative Accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the offset to the full scale of the device. See "Measuring Offset Error".
[3]Operation of the 0 to 10 volt output range requires a minimum supply voltage of +11.4 volts.
[4]Passive pull-down resistance is 2kΩ for 2.56 volt range, 10kΩ for 10 volt range.
[5]Settling time is specified for a positive-going full-scale step to ±1/2LSB. Negative-going steps to zero are slower, but can be improved with an external pull-down.
[6]The full range output voltage for the 2.56 range is 2.55V and is guaranteed with a +5V supply, for the 10V range, it is 9.960V guaranteed with a +15V supply.
[7]A monotonic converter has a maximum differential linearity error of ±1LSB.

Specifications shown in **boldface** are tested on all production units at final electrical test.
Specifications subject to change without notice.

ANALOG DEVICES

High Speed 12-Bit Monolithic D/A Converters

AD565A*/AD566A*

FEATURES

- Single Chip Construction
- Very High-Speed Settling to 1/2LSB
  - AD565A: 250ns max
  - AD566A: 350ns max
- Full-Scale Switching Time: 30ns
- Guaranteed for Operation with ±12V Supplies: AD565A with -12V Supply: AD566A
- Linearity Guaranteed Over Temperature: 1/2LSB max (K, T Grades)
- Monotonicity Guaranteed Over Temperature
- Low Power: AD566A = 180mW max; AD565A = 225mW max
- Use with On-Board High-Stability Reference (AD565A) or with External Reference (AD566A)
- Low Cost
- MIL-STD-883-Compliant Versions Available

PRODUCT DESCRIPTION

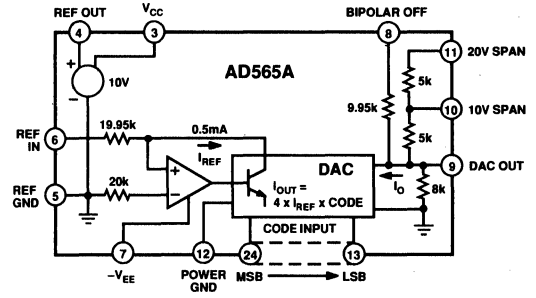
The AD565A and AD566A are fast 12-bit digital-to-analog converters which incorporate the latest advances in analog circuit design to achieve high speeds at low cost.

The AD565A and AD566A use 12 precision, high-speed bipolar current-steering switches, control amplifier and a laser-trimmed thin-film resistor network to produce a very fast, high accuracy analog output current. The AD565A also inclues:s a buried zener reference that features low-noise, long-term stability and temperature drift characteristics comparable to the best discrete reference diodes.

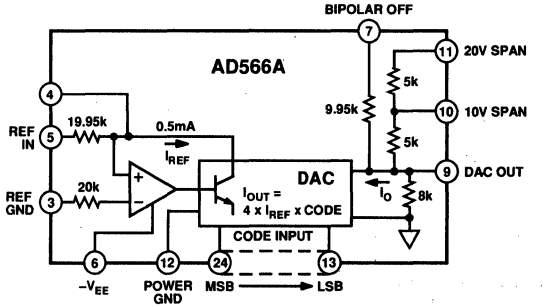
The combination of performance and flexibility in the AD565A and AD566A has resulted from major innovations in circuit design, an important new high-speed bipolar process, and continuing advances in laser-wafer-trimming techniques (LWT). The AD565A and AD566A have a 10-90% full-scale transition time less than 35ns and settle to within ±1/2LSB in 250ns max (350ns for AD566A). Both are laser-trimmed at the wafer level to ±1/8LSB typical linearity and are specified to ±1/4LSB max error (K and T grades) at +25°C. High speed and accuracy make the AD565A and AD566A the ideal choice for high-speed display drivers as well as fast analog-to-digital converters.

The laser trimming process which provides the excellent linearity is also used to trim both the absolute value and the tempert ture coefficient of the reference of the AD565A resulting in a typical full-scale gain TC of 10 ppm/°C. When tighter TC performance is required or when a system reference is available, the AD566A may be used with an external reference.

AD565A FUNCTIONAL BLOCK DIAGRAM



AD566A FUNCTIONAL BLOCK DIAGRAM



AD565A and AD566A are available in four performance grades. The J and K are specified for use over the 0 to +70°C temperature range while the S and T grades are specified for the −55°C to +125°C range. The D grades are all packaged in a 24-pin, hermetically sealed, ceramic, dual-in-line package. The JR grade is packaged in a 28-pin plastic SOIC.

PRODUCT HIGHLIGHTS

1. The wide output compliance range of the AD565A and AD566A are ideally suited for fast, low noise, accurate voltage output configurations without an output amplifier.
2. The devices incorporate a newly developed, fully differential, nonsaturating precision current switching cell structure which combines the dc accuracy and stability first developed in the AD562/3 with very fast switching times and an optimally-damped settling characteristic.
3. The devices also contain SiCr thin film application resistors which can be used with an external op amp to provide a precision voltage output or as input resistors for a successive approximation A/D converter. The resistors are matched to the internal ladder network to guarantee a low gain temperature coefficient and are laser-trimmed for minimum full-scale and bipolar offset errors.
4. The AD565A and AD566A are available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current /883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD565A—SPECIFICATIONS (T_A = +25°C, V_{CC} = +15V, V_{EE} = +15V, unless otherwise specified.)

POWER DISSIPATION		225	345		225	345	mW

NOTES

[1] The digital inputs are guaranteed but not tested over the operating temperature range.

[2] The power supply gain sensitivity is tested in reference to a V_{CC}, V_{EE} of ±15V dc.

[3] For operation at elevated temperatures the reference cannot supply current for external loads. It, therefore, should be buffered if additional loads are to be supplied.

Specifications subject to change without notice.

ANALOG DEVICES

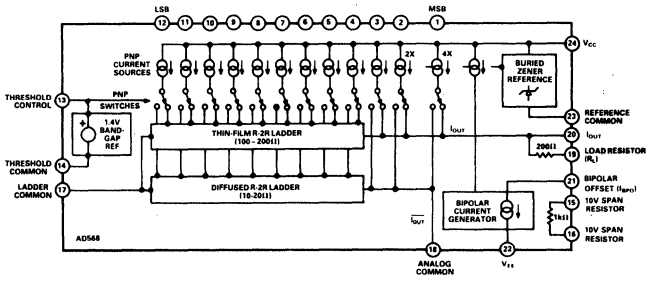
12-Bit Ultrahigh Speed Monolithic D/A Converter

AD568

FEATURES

- Ultrahigh Speed: Current Settling to 1LSB in 35ns
- High Stability Buried Zener Reference on Chip
- Monotonicity Guaranteed Over Temperature
- 10.24mA Full-Scale Output Suitable for Video Applications
- Integral and Differential Linearity Guaranteed Over Temperature
- 0.3" "Skinny DIP" Packaging
- Variable Threshold Allows TTL and CMOS Interface
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD568 is an ultrahigh-speed, 12-bit digital-to-analog converter (DAC) settling to 0.025% in 35ns. The monolithic device is fabricated using Analog Devices' Complementary Bipolar (CB) Process. This is a proprietary process featuring high-speed NPN and PNP devices on the same chip without the use of dielectric isolation or multichip hybrid techniques. The high speed of the AD568 is maintained by keeping impedance levels low enough to minimize the effects of parasitic circuit capacitances.

The DAC consists of 16 current sources configured to deliver a 10.24mA full-scale current. Multiple matched current sources and thin-film ladder techniques are combined to produce bit weighting. The DAC's output is a 10.24mA full scale (FS) for current output applications or a 1.024V FS unbuffered voltage output. Additionally, a 10.24V FS buffered output may be generated using an onboard 1kΩ span resistor with an external op amp. Bipolar ranges are accomplished by pin strapping.

Laser wafer trimming insures full 12-bit linearity. All grades of the AD568 are guaranteed monotonic over their full operating temperature range. Furthermore, the output resistance of the DAC is trimmed to 100Ω ± 1.0%. The gain temperature coefficient of the voltage output is 30ppm/°C max (K).

The AD568 is available in three performance grades. The AD568JQ and KQ are available in 24-pin cerdip (0.3") packages and are specified for operation from 0 to +70°C. The AD568SQ features operation from −55°C to +125°C and is also packaged in the hermetic 0.3" cerdip.

PRODUCT HIGHLIGHTS

1. The ultrafast settling time of the AD568 allows leading edge performance in waveform generation, graphics display and high-speed A/D conversion applications.
2. Pin strapping provides a variety of voltage and current output ranges for application versatility. Tight control of the absolute output current reduces trim requirements in externally-scaled applications.
3. Matched on-chip resistors can be used for precision scaling in high-speed A/D conversion circuits.
4. The digital inputs are compatible with TTL and +5V CMOS logic families.
5. Skinny DIP (0.3") packaging minimizes board space requirements and eases layout considerations.
6. The AD568 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD568/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Definitions

LINEARITY ERROR (also called INTEGRAL NON-LINEARITY OR INL): Analog Devices defines linearity error as the maximum deviation of the actual analog output from the ideal output (a straight line drawn from 0 to FS) for any bit combination expressed in multiples of 1LSB. The AD568 is laser trimmed to 1/4LSB (0.006% of FS) maximum linearity error at +25°C for the K version and 1/2LSB for the J and S versions.

DIFFERENTIAL LINEARITY ERROR (also called DIFFERENTIAL NONLINEARITY or DNL): DNL is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in digital input code. Monotonic behavior requires that the differential linearity error not exceed 1LSB in the negative direction.

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant as the digital input increases.

UNIPOLAR OFFSET ERROR: The deviation of the analog output from the ideal (0V or 0mA) when the inputs are set to all 0s is called unipolar offset error.

BIPOLAR OFFSET ERROR: The deviation of the analog output from the ideal (negative half-scale) when the inputs are set to all 0s is called bipolar offset error.

BIPOLAR ZERO ERROR: The deviation of the analog output from the ideal half-scale output of 0V (or 0mA) for bipolar mode when only the MSB is on (100.....00) is called bipolar zero error.

GAIN ERROR: The difference between the ideal and actual output span of FS − 1LSB, expressed in % of FS, or LSB, when all bits are on.

GLITCH IMPULSE: Asymmetrical switching times in a DAC give rise to undesired output transients which are quantified by their glitch impulse. It is specified as the net area of the glitch in nV-sec or pA-sec.

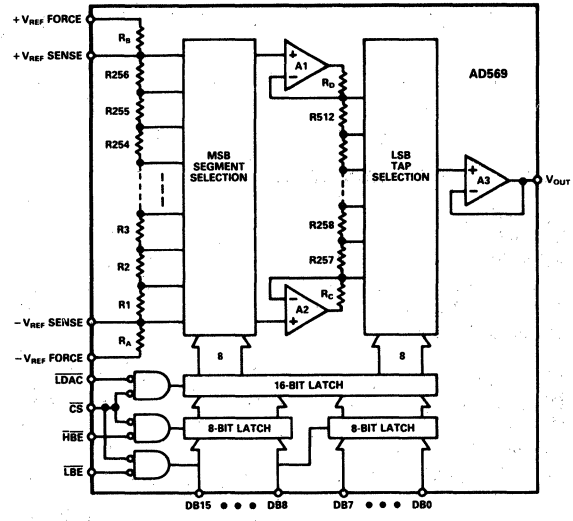
16-Bit Monotonic Voltage Output D/A Converter

AD569

FEATURES
Guaranteed 16-Bit Monotonicity
Monolithic BiMOS II Construction
±0.01% Typical Nonlinearity
8- and 16-Bit Bus Compatibility
3μs Settling to 16-Bits
Low Drift
Low Power
Low Noise

APPLICATIONS
Robotics
Closed-Loop Positioning
High-Resolution ADCs
Microprocessor-Based Process Control
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD569 is a monolithic 16-bit digital-to-analog converter (DAC) manufactured in Analog Devices' BiMOS II process. BiMOS II allows the fabrication of low power CMOS logic functions on the same chip as high precision bipolar linear circuitry. The AD569 chip includes two resistor strings, selector switches, decoding logic, buffer amplifiers, and double-buffered input latches.

The AD569's voltage-segmented architecture insures 16-bit monotonicity over time and temperature. Integral nonlinearity is maintained at ±0.01%, while differential nonlinearity is ±0.0004%. The on-chip, high-speed buffer amplifiers provide a voltage output settling time of 3μs to within ±0.001% for a full-scale step.

The reference input voltage which determines the output range can be either unipolar or bipolar. Nominal reference range is ±5V and separate reference force and sense connections are provided for high accuracy applications. The AD569 can operate with an ac reference in multiplying applications.

Data may be loaded into the AD569's input latches from 8- and 16-bit buses. The double-buffered structure simplifies 8-bit bus interfacing and allows multiple DACs to be loaded asynchronously and updated simultaneously. Four TTL/LSTTL/5V CMOS-compatible signals control the latches: $\overline{CS}$, $\overline{LBE}$, $\overline{HBE}$, and $\overline{LDAC}$.

The AD569 is available in five grades: J and K versions are specified from 0 to +70°C and are packaged in a 28-pin plastic DIP and 28-pin PLCC package; AD and BD versions are specified from −25°C to +85°C and are packaged in a 28-pin ceramic DIP. The SD version, also in a 28-pin ceramic DIP, is specified from −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. Monotonicity to 16 bits is insured by the AD569's voltage-segmented architecture.
2. The output range is ratiometric to an external reference or ac signal. Gain error and gain drift of the AD569 are negligible.
3. The AD569's versatile data input structure allows loading from 8- and 16-bit buses.
4. The on-chip output buffer amplifier can supply ±5V into a 1kΩ load, and can drive capacitive loads of up to 1000pF.
5. Kelvin connections to the reference inputs preserve the gain and offset accuracy of the transfer function in the presence of wiring resistances and ground currents.
6. The AD569 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD569/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Lead Temperature Range (Soldering, 10secs) . . . . . +300°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

3

ESD SENSITIVITY

The AD569 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high-energy discharges (Human Body Model) and fast, low-energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD569 has been classified as a Category A device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' ESD Prevention Manual.

Monolithic 16-Bit Serial/Byte DACPORT

AD660

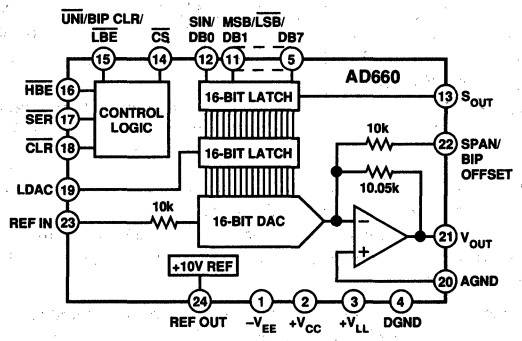
FEATURES

Complete 16-Bit D/A Function
- **On-Chip Output Amplifier**
- **On-Chip Buried Zener Voltage Reference**

±1 LSB Integral Linearity
15-Bit Monotonic over Temperature
Microprocessor Compatible
- **Serial or Byte Input**
- **Double Buffered Latches**
- **Fast (40 ns) Write Pulse**

Asynchronous Clear (to 0 V) Function
Serial Output Pin Facilitates Daisy Chaining
Unipolar or Bipolar Output
Low Glitch: 15 nV-s
Low THD+N: 0.009%

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD660 DACPORT® is a complete 16-bit monolithic D/A converter with an on-board voltage reference, double buffered latches and output amplifier. It is manufactured on Analog Devices' BiMOS II process. This process allows the fabrication of low power CMOS logic functions on the same chip as high precision bipolar linear circuitry.

The AD660's architecture ensures 15-bit monotonicity over time and temperature. Integral and differential nonlinearity is maintained at ±0.003% max. The on-chip output amplifier provides a voltage output settling time of 10 μs to within 1/2 LSB for a full-scale step.

The AD660 has an extremely flexible digital interface. Data can be loaded into the AD660 in serial mode or as two 8-bit bytes. This is made possible by two digital input pins which have dual functions. The serial mode input format is pin selectable to be MSB or LSB first. The serial output pin allows the user to daisy chain several AD660s by shifting the data through the input latch into the next DAC thus minimizing the number of control lines required to SIN, $\overline{CS}$ and LDAC. The byte mode input format is also flexible in that the high byte or low byte data can be loaded first. The double buffered latch structure eliminates data skew errors and provides for simultaneous updating of DACs in a multi-DAC system.

The AD660 is available in five grades. AN and BN versions are specified from −40°C to +85°C and are packaged in a 24-pin 300 mil plastic DIP. AR and BR versions are also specified from −40°C to +85°C and are packaged in a 24-pin SOIC. The SQ version is packaged in a 24-pin 300 mil cerdip package and is also available compliant to MIL-STD-883. Refer to the AD660/883B data sheet for specifications and test conditions.

DACPORT is a registered trademark of Analog Devices, Inc.

PRODUCT HIGHLIGHTS

1. The AD660 is a complete 16-bit DAC, with a voltage reference, double buffered latches and output amplifier on a single chip.
2. The internal buried Zener reference is laser trimmed to 10.000 volts with a ±0.1% maximum error and a temperature drift performance of ±15 ppm/°C. The reference is available for external applications.
3. The output range of the AD660 is pin programmable and can be set to provide a unipolar output range of 0 V to +10 V or a bipolar output range of −10 V to +10 V. No external components are required.
4. The AD660 is both dc and ac specified. DC specifications include ±1 LSB INL and ±1 LSB DNL errors. AC specifications include 0.009% THD+N and 83 dB SNR.
5. The double buffered latches on the AD660 eliminate data skew errors and allow simultaneous updating of DACs in multi-DAC applications.
6. The CLEAR function can asynchronously set the output to 0 V regardless of whether the DAC is in unipolar or bipolar mode.
7. The output amplifier settles within 10 μs to ±1/2 LSB for a full-scale step and within 2.5 μs for a 1 LSB step over temperature. The output glitch is typically 15 nV-s when a full-scale step is loaded.

NOTES

[1]For 16-bit resolution, 1 LSB = 0.0015% of FSR. For 15-bit resolution, 1 LSB = 0.003% of FSR. For 14-bit resolution, 1 LSB = 0.006% of FSR. FSR stands for Full-Scale Range and is 10 V in a Unipolar Mode and 20 V in Bipolar Mode.

[2]Gain error and gain drift are measured using the internal reference. The internal reference is the main contributor to gain drift. If lower gain drift is required, the AD660 can be used with a precision external reference such as the AD587, AD586 or AD688.

[3]Gain Error is measured with fixed 50 Ω resistors as shown in the Application section. Eliminating these resistors increases the gain error by 0.25% of FSR (Unipolar mode) or 0.50% of FSR (Bipolar mode).

[4]DAC Gain Error and Drift are measured with an external voltage reference. They represent the error contributed by the DAC alone, for use with an external reference.

[5]External current is defined as the current available in addition to that supplied to REF IN and SPAN/BIPOLAR OFFSET on the AD660.

[6]Operation on ±12 V supplies is possible using an external reference such as the AD586 and reducing the output range. Refer to the Internal/External Reference section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD660 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

DEFINITIONS OF SPECIFICATIONS

INTEGRAL NONLINEARITY: Analog Devices defines integral nonlinearity as the maximum deviation of the actual, adjusted DAC output from the ideal analog output (a straight line drawn from 0 to FS–1 LSB) for any bit combination. This is also referred to as relative accuracy.

DIFFERENTIAL NONLINEARITY: Differential nonlinearity is the measure of the change in the analog output, normalized to full scale, associated with a 1 LSB change in the digital input code. Monotonic behavior requires that the differential linearity error be greater than or equal to −1 LSB over the temperature range of interest.

MONOTONICITY: A DAC is monotonic if the output either increases or remains constant for increasing digital inputs with the result that the output will always be a single-valued function of the input.

GAIN ERROR: Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been adjusted out.

OFFSET ERROR: Offset error is a combination of the offset errors of the voltage-mode DAC and the output amplifier and is measured with all 0s loaded in the DAC.

BIPOLAR ZERO ERROR: When the AD660 is connected for bipolar output and 10 . . . 000 is loaded in the DAC, the deviation of the analog output from the ideal midscale value of 0 V is called the bipolar zero error.

DRIFT: Drift is the change in a parameter (such as gain, offset and bipolar zero) over a specified temperature range. The drift temperature coefficient, specified in ppm/°C, is calculated by measuring the parameter at T_{MIN}, 25°C and T_{MAX} and dividing the change in the parameter by the corresponding temperature change.

TOTAL HARMONIC DISTORTION + NOISE: Total harmonic distortion + noise (THD+N) is defined as the ratio of the square root of the sum of the squares of the values of the harmonics and noise to the value of the fundamental input frequency. It is usually expressed in percent (%).

THD+N is a measure of the magnitude and distribution of linearity error, differential linearity error, quantization error and noise. The distribution of these errors may be different, depending upon the amplitude of the output signal. Therefore, to be the most useful, THD+N should be specified for both large and small signal amplitudes.

SIGNAL-TO-NOISE RATIO: The signal-to-noise ratio is defined as the ratio of the amplitude of the output when a full-scale signal is present to the output with no signal present. This is measured in dB.

DIGITAL-TO-ANALOG GLITCH IMPULSE: This is the amount of charge injected from the digital inputs to the analog output when the inputs change state. This is measured at half scale when the DAC switches around the MSB and as many as possible switches change state, i.e., from 011 . . . 111 to 100 . . . 000.

DIGITAL FEEDTHROUGH: When the DAC is not selected (i.e., $\overline{CS}$ is held high), high frequency logic activity on the digital inputs is capacitively coupled through the device to show up as noise on the V_{OUT} pin. This noise is digital feedthrough.

THEORY OF OPERATION

The AD660 uses an array of bipolar current sources with MOS current steering switches to develop a current proportional to the applied digital word, ranging from 0 to 2 mA. A segmented architecture is used, where the most significant four data bits are thermometer decoded to drive 15 equal current sources. The lesser bits are scaled using a R–2R ladder, then applied together with the segmented sources to the summing node of the output amplifier. The internal span/bipolar offset resistor can be connected to the DAC output to provide a 0 V to +10 V span, or it can be connected to the reference input to provide a −10 V to +10 V span.

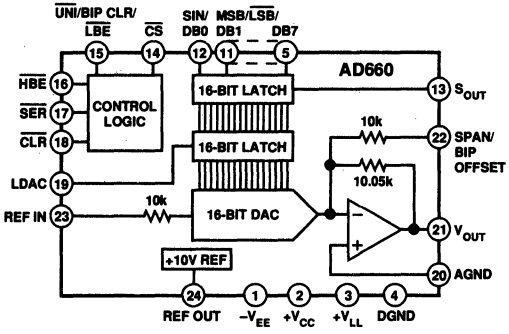

Figure 2. AD660 Functional Block Diagram

ANALOG CIRCUIT CONNECTIONS

Internal scaling resistors provided in the AD660 may be connected to produce a unipolar output range of 0 V to +10 V or a bipolar output range of −10 V to +10 V. Gain and offset drift are minimized in the AD660 because of the thermal tracking of the scaling resistors with other device components.

UNIPOLAR CONFIGURATION

The configuration shown in Figure 3a will provide a unipolar 0 V to +10 V output range. In this mode, 50 Ω resistors are tied between the span/bipolar offset terminal (Pin 22) and V_{OUT} (Pin 21), and between REF OUT (Pin 24) and REF IN (Pin 23). It is possible to use the AD660 without any external components by tying Pin 24 directly to Pin 23 and Pin 22 directly to Pin 21. Eliminating these resistors will increase the gain error by 0.25% of FSR.

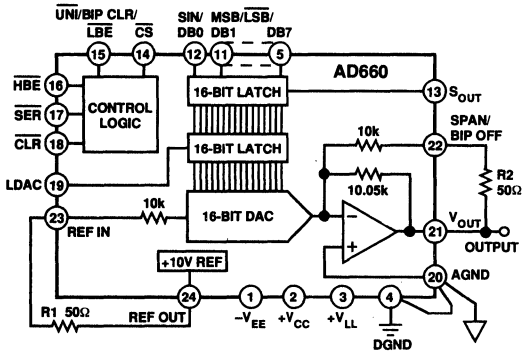

Figure 3a. 0 V to +10 V Unipolar Voltage Output

If it is desired to adjust the gain and offset errors to zero, this can be accomplished using the circuit shown in Figure 3b. The adjustment procedure is as follows:

STEP1 . . . ZERO ADJUST

Turn all bits OFF and adjust zero trimmer, R4, until the output reads 0.000000 volts (1 LSB = 153 μV).

STEP 2 . . . GAIN ADJUST

Turn all bits ON and adjust gain trimmer, R1, until the output is 9.999847 volts. (Full scale is adjusted to 1 LSB less than the nominal full scale of 10.000000 volts).

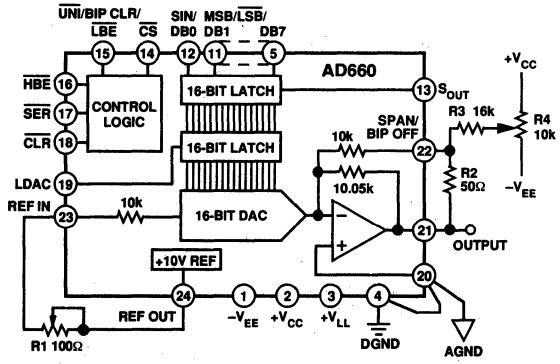

Figure 3b. 0 V to +10 V Unipolar Voltage Output with Gain and Offset Adjustment

BIPOLAR CONFIGURATION

The circuit shown in Figure 4a will provide a bipolar output voltage from −10.000000 V to +9.999694 V with positive full scale occurring with all bits ON. As in the unipolar mode, resistors R1 and R2 may be eliminated altogether to provide AD660 bipolar operation without any external components. Eliminating these resistors will increase the gain error by 0.50% of FSR in the bipolar mode.

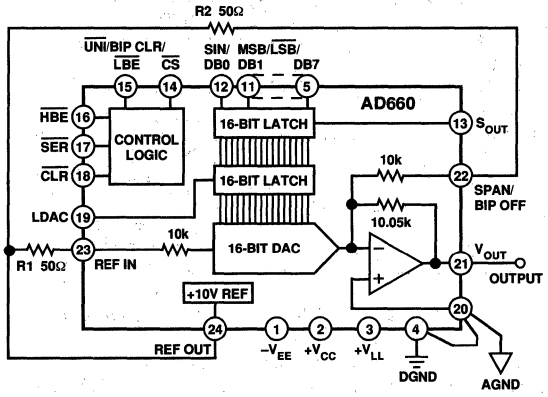

Figure 4a. ±10 V Bipolar Voltage Output

Gain offset and bipolar zero errors can be adjusted to zero using the circuit shown in Figure 4b as follows:

STEP I . . . OFFSET ADJUST

Turn OFF all bits. Adjust trimmer R2 to give −10.000000 volts output.

STEP II . . . GAIN ADJUST

Turn all bits ON and adjust R1 to give a reading of +9.999694 volts.

STEP III . . . BIPOLAR ZERO ADJUST (Optional)

In applications where an accurate zero output is required, set the MSB ON, all other bits OFF, and readjust R2 for zero volts output.

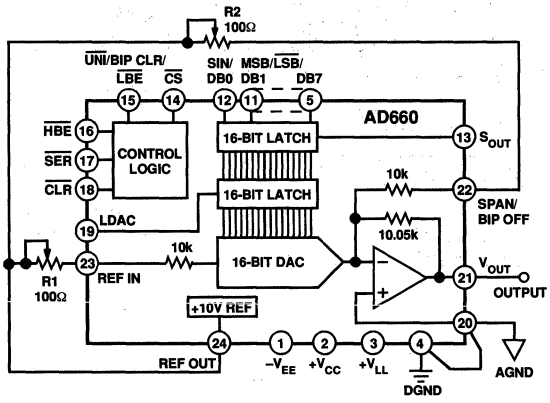

Figure 4b. ±10 V Bipolar Voltage Output with Gain and Offset Adjustment

It should be noted that using external resistors will introduce a small temperature drift component beyond that inherent in the AD660. The internal resistors are trimmed to ratio-match and temperature-track other resistors on chip, even though their absolute tolerances are ±20% and absolute temperature coefficients are approximately −50 ppm/°C. In the case that external resistors are used, the temperature coefficient mismatch between internal and external resistors, multiplied by the sensitivity of the circuit to variations in the external resistor value, will be the resultant additional temperature drift.

INTERNAL/EXTERNAL REFERENCE USE

The AD660 has an internal low noise buried Zener diode reference which is trimmed for absolute accuracy and temperature coefficient. This reference is buffered and optimized for use in a high speed DAC and will give long-term stability equal or superior to the best discrete Zener diode references. The performance of the AD660 is specified with the internal reference driving the DAC and with the DAC alone (for use with a precision external reference).

The internal reference has sufficient buffering to drive external circuitry in addition to the reference currents required for the DAC (typically 1 mA to REF IN and 1 mA to BIPOLAR OFFSET). A minimum of 2 mA is available for driving external loads. The AD660 reference output should be buffered with an external op amp if it is required to supply more than 4 mA total current. The reference is tested and guaranteed to ±0.2% max error.

It is also possible to use external references other than 10 volts with slightly degraded linearity specifications. The recommended range of reference voltages is +5 V to +10.24 V, which allows 5 V, 8.192 V and 10.24 V ranges to be used. For example, by using the AD586 5 V reference, outputs of 0 V to +5 V unipolar or ±5 V bipolar can be realized. Using the AD586 voltage reference makes it possible to operate the AD660 with ±12 V supplies with 10% tolerances.

Figure 5 shows the AD660 using the AD586 precision 5 V reference in the bipolar configuration. The highest grade AD586MN is specified with a drift of 2 ppm/°C which is a 7.5× improvement over the AD660's internal reference. This circuit includes two optional potentiometers and one optional resistor that can be used to adjust the gain, offset and bipolar zero errors in a manner similar to that described in the BIPOLAR CONFIGURATION section. Use −5.000000 V and +4.999847 as the output values.

The AD660 can also be used with the AD587 10 V reference, using the same configuration shown in Figure 5 to produce a ±10 V output. The highest grade AD587LR, N is specified at 5 ppm/°C, which is a 3× improvement over the AD660's internal reference.

Figure 6 shows the AD660 using the AD680 precision ±10 V reference, in the unipolar configuration. The highest grade AD688BQ is specified with a temperature coefficient of 1.5 ppm/°C. The ±10 V output is also ideal for providing precise biasing for the offset trim resistor R4.

3

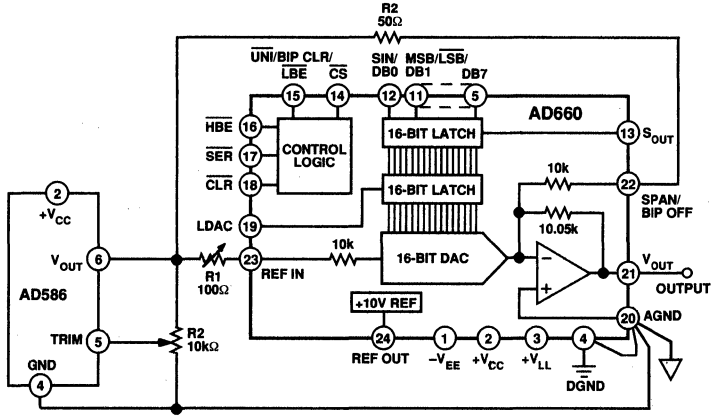

Figure 5. Using the AD660 with the AD586 5 V Reference

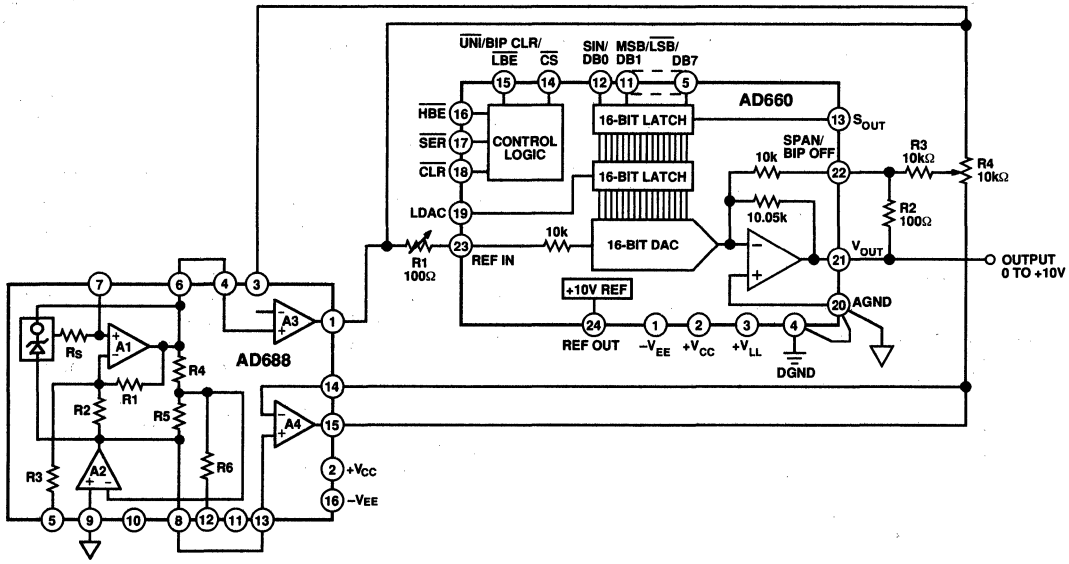

Figure 6. Using the AD660 with the AD688 High Precision ±10 V Reference

OUTPUT SETTLING AND GLITCH

The AD660's output buffer amplifier typically settles to within 0.0008% FS (1/2 LSB) of its final value in 8 μs for a full-scale step. Figures 7a and 7b show settling for a full-scale and an LSB step, respectively, with a 2 kΩ, 1000 pF load applied. The guaranteed maximum settling time at +25°C for a full-scale step is 13 μs with this load. The typical settling time for a 1 LSB step is 2.5 μs.

The digital-to-analog glitch impulse is specified as 15 nV-s typical. Figure 7c shows the typical glitch impulse characteristic at the code 011 . . . 111 to 100 . . . 000 transition when loading the second rank register from the first rank register.

Figure 7. Output Characteristics

DIGITAL CIRCUIT DETAILS

The AD660 has several "dual-use" pins which allow flexible operation while maintaining the lowest possible pin count and consequently the smallest package size. The user should, therefore, pay careful attention to the following information when applying the AD660.

Data can be loaded into the AD660 in serial or byte mode as described below.

Serial Mode Operation is enabled by bringing $\overline{\text{SER}}$ (Pin 17) low. This changes the function of DB0 (Pin 12) to that of the serial input pin, SIN. It also changes the function of DB1 (Pin 11) to a control input that tells the AD660 whether the serial data is going to be loaded MSB or $\overline{\text{LSB}}$ first.

In serial mode $\overline{\text{HBE}}$ and $\overline{\text{LBE}}$ are effectively disabled except for $\overline{\text{LBE}}$'s dual function which is to control whether the user wishes to have the asynchronous clear function go to unipolar or bipolar zero. (A low on $\overline{\text{LBE}}$, when $\overline{\text{CLR}}$ is strobed, sends the DAC output to unipolar zero, a high to bipolar zero.) The AD660 does not care about the status of HBE when in serial mode.

Data is clocked into the input register on the rising edge of $\overline{\text{CS}}$ as shown in Figure 1b. The data is then resident in the first rank latch and can be loaded into the DAC latch by taking LDAC high. This will cause the DAC to change to the appropriate output value.

It should be noted that the clear function clears the DAC latch but does not clear the first rank latch. Therefore, the data that was previously resident in the first rank latch can be reloaded simply by bringing LDAC high after the event that necessitated $\overline{\text{CLR}}$ to be strobed has ended. Alternatively, new data can be loaded into the first rank latch if desired.

The serial out pin (SOUT) can be used to daisy chain several DACs together in multi-DAC applications to minimize the number of isolators being used to cross an intrinsic safety barrier. The first rank latch simply acts like a 16-bit shift register, and repeated strobing of $\overline{\text{CS}}$ will shift the data out through SOUT and into the next DAC. Each DAC in the chain will require its own LDAC signal unless all of the DACs are to be updated simultaneously.

Byte Mode Operation is enabled simply by keeping $\overline{\text{SER}}$ high, which configures DB0–DB7 as data inputs. In this mode $\overline{\text{HBE}}$ and $\overline{\text{LBE}}$ are used to identify the data as either the high byte or low byte of the 16-bit input word. (The user can load the data, in any order, into the first rank latch.) As in the serial mode case, the status of $\overline{\text{LBE}}$, when $\overline{\text{CLR}}$ is strobed determines whether the AD660 clears to unipolar or bipolar zero. Therefore, when in byte mode, the user must take care to set $\overline{\text{LBE}}$ to the desired status before strobing $\overline{\text{CLR}}$. (In serial mode the user can simply hardware $\overline{\text{LBE}}$ to the desired state.)

NOTE: $\overline{\text{CS}}$ is edge triggered. $\overline{\text{HBE}}$, $\overline{\text{LBE}}$ and LDAC are level triggered.

AD660 TO MC68HC11 (SPI BUS) INTERFACE

The AD660 interface to the Motorola SPI (serial peripheral interface) is shown in Figure 8. The MOSI, SCK, and $\overline{SS}$ pins of the HC11 are respectively connected to the BIT0, $\overline{CS}$ and LDAC pins of the AD660. The $\overline{SER}$ pin of the AD660 is tied low causing the first rank latch to be transparent. The majority of the interfacing issues are taken care of in the software initialization. A typical routine such as the one shown below begins by initializing the state of the various SPI data and control registers.

The most significant data byte (MSBY) is then retrieved from memory and processed by the SENDAT subroutine. The $\overline{SS}$ pin is driven low by indexing into the PORTD data register and clear Bit 5. This causes the 2nd rank latch of the AD660 to become transparent. The MSBY is then set to the SPI data register where it is automatically transferred to the AD660.

The HC11 generates the requisite 8 clock pulses with data valid on the rising edges. After the most significant byte is transmitted, the least significant byte (LSBY) is loaded from memory and transmitted in a similar fashion. To complete the transfer, the LDAC pin is driven high latching the complete 16-bit word into the AD660.

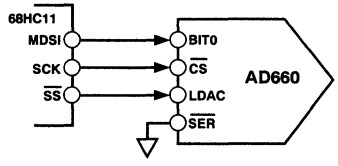

Figure 8. AD660 to 68HC11 (SPI) Interface

AD660 TO MICROWIRE INTERFACE

The flexible serial interface of the AD660 is also compatible with the National Semiconductor MICROWIRE™ interface. The MICROWIRE interface is used on microcontrollers such as the COP400 and COP800 series of processors. A generic interface to the MICROWIRE interface is shown in Figure 9. The G1, SK, And SO pins of the MICROWIRE interface are respectively connected to the LDAC, $\overline{CS}$ and BIT0 pins of the AD660.

MICROWIRE is a registered trademark of National Semiconductor.

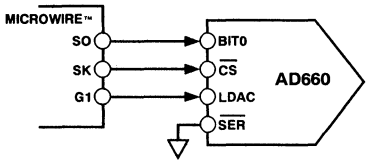

Figure 9. AD660 to MICROWIRE Interface

3

AD660 TO ADSP-210x FAMILY INTERFACE

The serial mode of the AD660 minimizes the number of control and data lines required to interface to digital signal processors (DSPs) such as the ADSP-210x family. The application in Figure 10 shows the interface between an ADSP-2101 and the AD660. Both the TFS pin and the DT pins of the ADSP-2101 should be connected to the $\overline{SER}$ and BIT0 pins of the AD660, respectively. An inverter is required between the SCLK output and the $\overline{CS}$ input of the AD660 in order to assure that data transmitted to the BIT0 pin is valid on the rising edge of $\overline{CS}$.

The serial port (SPORT) of the DSP should be configured for alternate framing mode so that TFS complies with the word-length framing requirement of $\overline{SER}$. Note that the INVTFS bit in the SPORT control register should be set to invert the TFS signal so that $\overline{SER}$ is the correct polarity. The LDAC signal, which must meet the minimum hold specification of t_{IH}, is easily generated by delaying the rising edge of $\overline{SER}$ with a 74HC74 flip-flop. The $\overline{CS}$ signal clocks the flip-flop resulting in a delay of approximately one $\overline{CS}$ clock cycle.

In applications such as waveform generation, accurate timing of the output samples is important to avoid noise that would be induced by jitter on the LDAC signal. In this example, the ADSP-2101 is set up to use the internal timer to interrupt the processor at the precise and desired sample rate. When the timer interrupt occurs, the processors's 16-bit data word is written to the transmit register (TXn). This causes the DSP to automatically generate the TFS signal and begin transmission of the data.

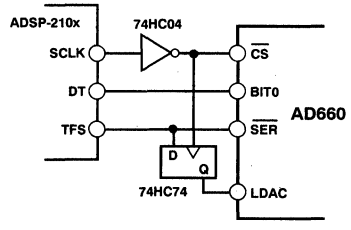

Figure 10. AD660 to ADSP-210x Interface

AD660 TO Z80 INTERFACE

Figure 11 shows a Zilog Z-80 8-bit microprocessor connected to the AD660 using the byte mode interface. The double-buffered capability of the AD660 allows the microprocessor to independently write to the low and high byte registers, and update the DAC output. Processor speeds up to 6 MHz on Z-80B require no extra wait states to interface with the AD660 using a 74ALS138 as the address decoder.

The address decoder analyzes the input-output address produced by the processor to select the function to be performed by the AD660, qualified by the coincidence of the Input-Output Request (IORQ*) and Write (WR*) pins. The least significant address bit (A0) determines if the low or high byte register of the AD660 is active. More significant address bits select between input register loading, DAC output update, and unipolar or bipolar clear.

A typical Z-80 software routine begins by writing the low byte of the desired 16-bit DAC data to address 0, followed by the high byte to address 1. The DAC output is then updated by activating LDAC with a write to address 2 (or 3). A clear to unipolar zero occurs on a write to address 4, and a clear to bipolar zero is performed by a write to address 5. The actual data written to addresses 2 through 5 is irrelevant. The decoder can easily be expanded to control as many AD660s as required.

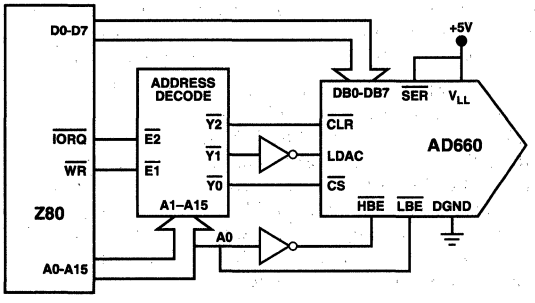

Figure 11. Connections for 8-Bit Bus Interface

NOISE

In high resolution systems, noise is often the limiting factor. A 16-bit DAC with a 10 volt span has an LSB size of 153 μV (−96 dB). Therefore, the noise floor must remain below this level in the frequency range of interest. The AD660's noise spectral density is shown in Figures 12 and 13. Figure 12 shows the DAC output noise voltage spectral density for a 20 V span excluding the reference. This figure shows the 1/f corner frequency at 100 Hz and the wideband noise to be below 120 nV/$\sqrt{\text{Hz}}$. Figure 13 shows the reference noise voltage spectral density. This figure shows the reference wideband noise to be below 125 nV/$\sqrt{\text{Hz}}$.

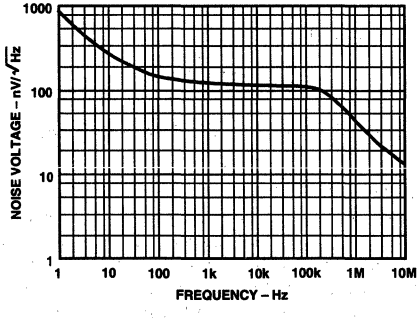

Figure 12. DAC Output Noise Voltage Spectral Density

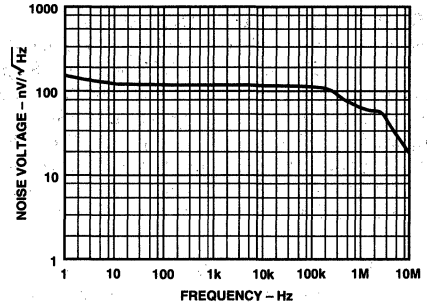

Figure 13. Reference Noise Voltage Spectral Density

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is the first issue. A 306 μA current through a 0.5 Ω trace will develop a voltage drop of 153 μV, which is 1 LSB at the 16-bit level for a 10 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals. Finally, power supplies need to be decoupled in order to filter out ac noise.

Analog and digital signals should not share a common path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes should also be used, with a single interconnection point to minimize ground loops. Analog signals should be routed as far as possible from digital signals and should cross them at right angles.

One feature that the AD660 incorporates to help the user layout is that the analog pins (V_{CC}, V_{EE}, REF OUT, REF IN, SPAN/BIP OFFSET, V_{OUT} and AGND) are adjacent to help isolate analog signals from digital signals.

SUPPLY DECOUPLING

The AD660 power supplies should be well filtered, well regulated, and free from high frequency noise. Switching power supplies are not recommended due to their tendency to generate spikes which can induce noise in the analog system.

Decoupling capacitors should be used in very close layout proximity between all power supply pins and ground. A 10 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor provides adequate decoupling. V_{CC} and V_{EE} should be bypassed to analog ground, while V_{LL} should be decoupled to digital ground.

An effort should be made to minimize the trace length between the capacitor leads and the respective converter power supply and common pins. The circuit layout should attempt to locate the AD660, associated analog circuitry and interconnections as far as possible from logic circuitry. A solid analog ground plane around the AD660 will isolate large switching ground currents. For these reasons, the use of wire wrap circuit construction is not recommended; careful printed circuit construction is preferred.

GROUNDING

The AD660 has two pins, designated analog ground (AGND) and digital ground (DGND.) The analog ground pin is the "high quality" ground reference point for the device. Any external loads on the output of the AD660 should be returned to analog ground. If an external reference is used, this should also be returned to the analog ground.

If a single AD660 is used with separate analog and digital ground planes, connect the analog ground plane to AGND and the digital ground plane to DGND keeping lead lengths as short as possible. Then connect AGND and DGND together at the AD660. If multiple AD660s are used or the AD660 shares analog supplies with other components, connect the analog and digital returns together once at the power supplies rather than at each chip. This single interconnection of grounds prevents large ground loops and consequently prevents digital currents from flowing through the analog ground.

Monolithic 12-Bit Quad DAC

AD664

FEATURES
Four Complete Voltage Output DACs
Data Register Readback Feature
"Reset to Zero" Override
Multiplying Operation
Double-Buffered Latches
Surface Mount and DIP Packages
MIL-STD-883 Compliant Versions Available

APPLICATIONS
Automatic Test Equipment
Robotics
Process Control
Disk Drives
Instrumentation
Avionics

PRODUCT DESCRIPTION

The AD664 is four complete 12-bit, voltage-output DACs on one monolithic IC chip. Each DAC has a double-buffered input latch structure and a data readback function. All DAC read and write operations occur through a single microprocessor-compatible I/O port.

The I/O port accommodates 4-, 8- or 12-bit parallel words allowing simple interfacing with a wide variety of microprocessors. A reset to zero control pin is provided to allow a user to simultaneously reset all DAC outputs to zero, regardless of the contents of the input latch. Any one or all of the DACs may be placed in a transparent mode allowing immediate response by the outputs to the input data.

The analog portion of the AD664 consists of four DAC cells, four output amplifiers, a control amplifier and switches. Each DAC cell is an inverting R-2R type. The output current from each DAC is switched to the on-board application resistors and output amplifier. The output range of each DAC cell is programmed through the digital I/O port and may be set to unipolar or bipolar range, with a gain of one or two times the reference voltage. All DACs are operated from a single external reference.

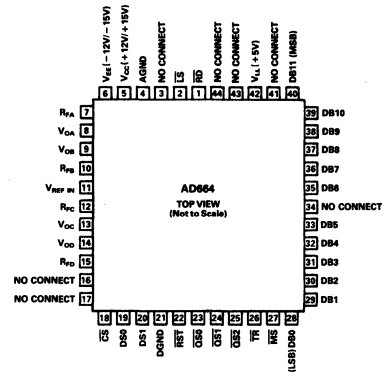
The functional completeness of the AD664 results from the combination of Analog Devices' BiMOS II process, laser-trimmed thin-film resistors and double-level metal interconnects.

PRODUCT HIGHLIGHTS

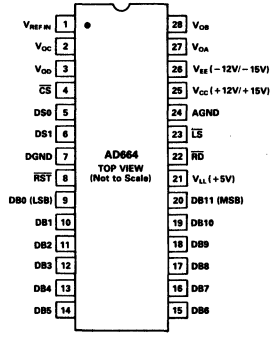
1. The AD664 provides four voltage-output DACs on one chip offering the highest density 12-bit D/A function available.
2. The output range of each DAC is fully and independently programmable.
3. Readback capability allows verification of contents of the internal data registers.

PIN CONFIGURATIONS

44-Pin Package



28-Pin DIP Package



4. The asynchronous RESET control returns all D/A outputs to zero volts.
5. DAC-to-DAC matching performance is specified and tested.
6. Linearity error is specified to be 1/2LSB at room temperature and 3/4LSB maximum for the K, B and T grades.
7. DAC performance is guaranteed to be monotonic over the full operating temperature range.
8. Readback buffers have tristate outputs.
9. Multiplying-mode operation allows use with fixed or variable, positive or negative external references.
10. The AD664 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD664/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]A minimum power supply of ±12.0V is required for 0 to +10V and ±10V operation. A minimum power supply of ±11.4V is required for −5V to +5V operation.

[2]For V_{CC}<12V and V_{EE}>−12V. Voltage not to exceed 10V maximum.

[3]Bipolar zero error is the difference from the ideal output (0 volts) and the actual output voltage with code 100 000 000 000 applied to the inputs.

[4]Linearity error is defined as the maximum deviation of the actual DAC output from the ideal output (a straight line drawn from 0 to F.S. −1LSB).

[5]FSR means Full-Scale Range and is 20V for ±10V range and 10V for ±5V range.

[6]A minimum power supply of ±12.0V is required for a 10V reference voltage.

[7]Analog Ground Current is input code dependent.

[8]Gain error matching is the largest difference in gain error between any two DACs in one package.

[9]Offset error matching is the largest difference in offset error between any two DACs in one package.

[10]Bipolar zero error matching is the largest difference in bipolar zero error between any two DACs in one package.

[11]Linearity error matching is the difference in the worst case linearity error between any two DACs in one package.

[12]44-pin versions only.

*Specifications same as JN/JP/AD/AJ/SD.

Specifications subject to change without notice.

Specifications shown in **boldface** are tested on all production units at final electrical test. Results from those test are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

ABSOLUTE MAXIMUM RATINGS*

(Specifications apply to all grades except where noted.)

V_{LL} to DGND . . . . . 0 to +7V
V_{CC} to DGND . . . . . 0 to +18V
V_{EE} to DGND . . . . . −18V to 0V
Soldering . . . . . +300°C, 10 sec
Power Dissipation 1000mW
AGND to DGND . . . . . −1V to +1V
Reference Input . . . . . $V_{REF} \leq \pm 10V$ and $V_{REF} \leq (V_{CC} - 2V, V_{EE} + 2V)$
V_{CC} to V_{EE} . . . . . 0 to +36V
Digital Inputs . . . . . −0.3V to +7V
Analog Outputs . . . . . Indefinite Shorts to V_{CC}, V_{LL}, V_{EE} and GND

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

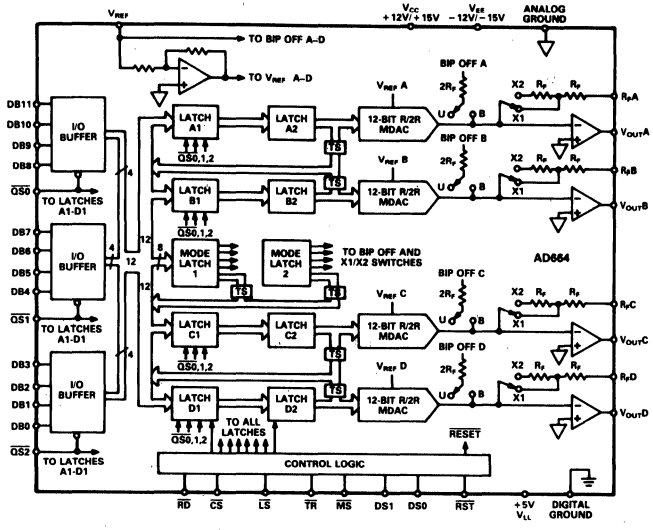

Figure 1a. 44-Pin Block Diagram

FUNCTIONAL DESCRIPTION

The AD664 combines four complete 12-bit voltage output D/A converters with a fast, flexible digital input/output port on one monolithic chip. It is available in two forms, a 44-pin version shown in Figure 1a and a 28-pin version shown in Figure 1b.

44-Pin Versions

Each DAC offers flexibility, accuracy and good dynamic performance. The R-2R structure is fabricated from thin-film resistors which are laser-trimmed to achieve 1/2LSB linearity and guaranteed monotonicity. The output amplifier combines the best features of the bipolar and MOS devices to achieve good dynamic performance and low offset. Settling time is under 10μs and each output can drive a 5mA, 500pF load. Short-circuit protection allows indefinite shorts to V_{LL}, V_{CC}, V_{EE} and GND. The output and span resistor pins are available separately. This feature allows a user to insert current-boosting elements to increase the drive capability of the system, as well as to overcome parasitics.

Digital circuitry is implemented in CMOS logic. The fast, low power, digital interface allows the AD664 to be interfaced with most microprocessors. Through this interface, the wide variety of features on each chip may be accessed. For example, the input data for each DAC is programmed by way of 4-, 8-, 12- or 16-bit words. The double-buffered input structure of this latch allows all four DACs to be updated simultaneously. A readback feature allows the internal registers to be read back through the same digital port, as either 4-, 8- or 12-bit words. When disabled, the readback drivers are placed in a high impedance (tristate) mode. A TRANSPARENT mode allows the input data to pass straight through both ranks of input registers and appear at the DAC with a minimum of delay. One D/A may be placed in the transparent mode at a time, or all four may be made transparent at once. The MODE SELECT feature allows the output range and mode of the DACs to be selected via the data bus inputs. An internal mode select register stores the selections. This register may also be read back to check its contents. A RESET-TO-ZERO feature allows all DACs to be reset to 0 volts out by strobing a single pin.

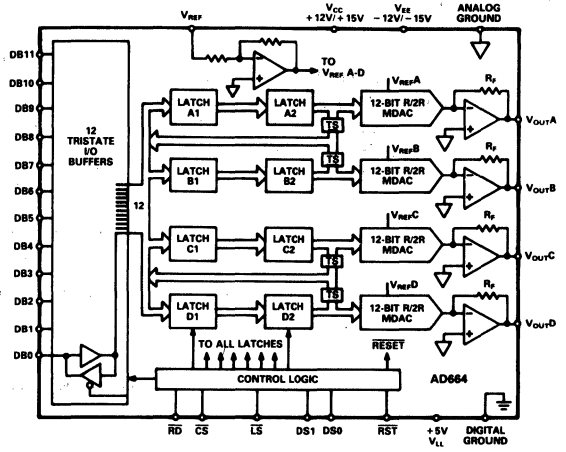

Figure 1b. 28-Pin Block Diagram

28-Pin Versions

The 28-pin versions are dedicated versions of the 44-pin AD664. Each offers a reduced set of features from those offered in the 44-pin version. This accommodates the reduced number of package pins available. Data is written and read with 12-bit words only. Output range and mode select functions are also not available in 28-pin versions. As an alternative, users specify either the UNI (unipolar, 0 to V_{REF}) models or the BIP (bipolar, $-V_{REF}$ to V_{REF}) models depending on the application requirements. Finally, the transparent mode is not available on the 28-pin versions.

Table I. Transfer Functions

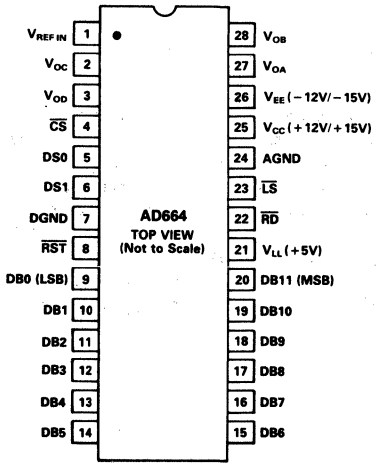
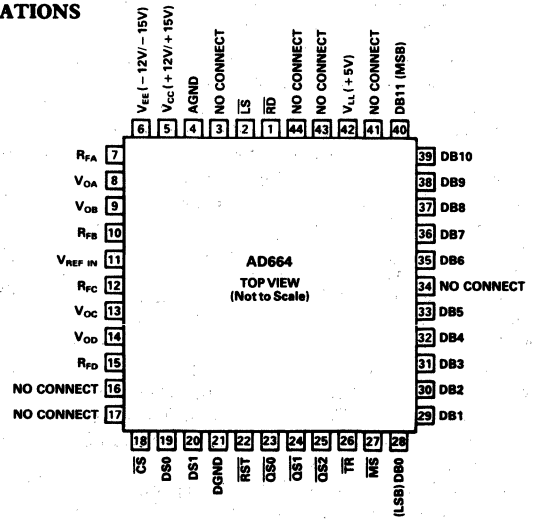
28-Pin DIP Package



44-Pin Package



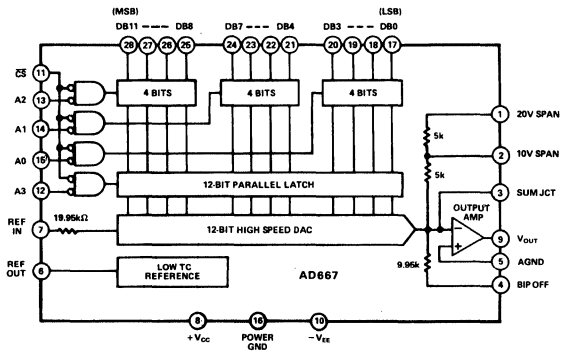
Microprocessor-Compatible 12-Bit D/A Converter

AD667*

FEATURES

- Complete 12-Bit D/A Function
  - Double-Buffered Latch
  - On Chip Output Amplifier
  - High Stability Buried Zener Reference
- Single Chip Construction
- Monotonicity Guaranteed Over Temperature
- Linearity Guaranteed Over Temperature: 1/2LSB max
- Settling Time: 3μs max to 0.01%
- Guaranteed for Operation with ±12V or ±15V Supplies
- Low Power: 300mW Including Reference
- TTL/5V CMOS Compatible Logic Inputs
- Low Logic Input Currents
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD667 is a complete voltage output 12-bit digital-to-analog converter including a high stability buried Zener voltage reference and double-buffered input latch on a single chip. The converter uses 12 precision high speed bipolar current steering switches and a laser trimmed thin film resistor network to provide fast settling time and high accuracy.

Microprocessor compatibility is achieved by the on-chip double-buffered latch. The design of the input latch allows direct interface to 4-, 8-, 12-, or 16-bit buses. The 12 bits of data from the first rank of latches can then be transferred to the second rank, avoiding generation of spurious analog output values. The latch responds to strobe pulses as short as 100ns, allowing use with the fastest available microprocessors.

The functional completeness and high performance in the AD667 results from a combination of advanced switch design, high speed bipolar manufacturing process, and the proven laser wafer-trimming (LWT) technology. The AD667 is trimmed at the wafer level and is specified to ±1/4LSB maximum linearity error (K, B grades) at 25°C and ±1/2LSB over the full operating temperature range.

The subsurface (buried) Zener diode on the chip provides a low-noise voltage reference which has long-term stability and temperature drift characteristics comparable to the best discrete reference diodes. The laser trimming process which provides the excellent linearity, is also used to trim the absolute value of the reference as well as its temperature coefficient. The AD667 is thus well suited for wide temperature range performance with ±1/2LSB maximum linearity error and guaranteed monotonicity over the full temperature range. Typical full scale gain T.C. is 5ppm/°C.

The AD667 is available in five performance grades. The AD667J and K are specified for use over the 0 to +70°C temperature range and are available in a 28-pin molded plastic DIP (N) or PLCC (P) package. The AD667S grade is specified for the −55°C to +125°C range and is available in the ceramic DIP (D) or LCC (E) package. The AD667A and B are specified for use over the −25°C to +85°C temperature range and are available in a 28-pin hermetically sealed ceramic DIP (D) package.

PRODUCT HIGHLIGHTS

1. The AD667 is a complete voltage output DAC with voltage reference and digital latches on a single IC chip.
2. The double-buffered latch structure permits direct interface to 4-, 8-, 12-, or 16-bit data buses. All logic inputs are TTL or 5 volt CMOS compatible.
3. The internal buried Zener reference is laser-trimmed to 10.00 volts with a ±1% maximum error. The reference voltage is also available for external application.
4. The gain setting and bipolar offset resistors are matched to the internal ladder network to guarantee a low gain temperature coefficient and are laser-trimmed for minimum full scale and bipolar offset errors.
5. The precision high speed current steering switch and on-board high speed output amplifier settle within 1/2LSB for a 10V full scale transition in 2.0μs when properly compensated.
6. The AD667 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD667/883B data sheet for detailed specifications.

NOTES
[1]The digital input specifications are 100% tested at +25°C, and guaranteed but not tested over the full temperature range.
[2]Adjustable to zero.
[3]FSR means "Full Scale Range" and is 20V for ±10V range and 10V for the ±5V range.
[4]A minimum power supply of ±12.5V is required for a ±10V full scale output and ±11.4V is required for all other voltage ranges.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

THE AD667 OFFERS TRUE 12-BIT PERFORMANCE OVER THE FULL TEMPERATURE RANGE

LINEARITY ERROR: Analog Devices defines linearity error as the maximum deviation of the actual, adjusted DAC output from the ideal analog output (a straight line drawn from 0 to F.S. – 1LSB) for any bit combination. The AD667 is laser trimmed to 1/4LSB (0.006% of F.S.) maximum error at +25°C for the K and B versions and 1/2LSB for the J, A and S versions.

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant for increasing digital inputs such that the output will always be a nondecreasing function of input. All versions of the AD667 are monotonic over their full operating temperature range.

DIFFERENTIAL NONLINEARITY: Monotonic behavior requires that the differential linearity error be less than 1LSB both at +25°C and over the temperature range of interest. Differential nonlinearity is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in digital input code. For example, for a 10 volt full scale output, a change of 1LSB in digital input code should result in a 2.44mV change in the analog output (1LSB = 10V × 1/4096 = 2.44mV). If in actual use, however, a 1LSB change in the input code results in a change of only 0.61mV (1/4LSB) in analog output, the differential linearity error would be −1.83mV, or −3/4LSB. The AD667K and B grades have a max differential linearity error of 1/2LSB, which specifies that every step will be at least 1/2LSB and at most 1 1/2 LSB.

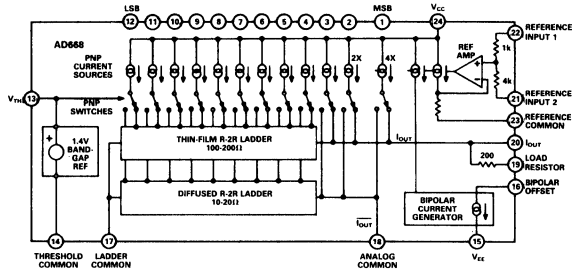
12-Bit Ultrahigh Speed Multiplying D/A Converter

AD668

FEATURES

Ultrahigh Speed: Current Settling to 1 LSB in 90 ns for a Full-Scale Change in Digital Input. Voltage Settling to 1 LSB in 120 ns for a Full-Scale Change in Analog Input
15 MHz Reference Bandwidth
Monotonicity Guaranteed over Temperature
10.24 mA Current Output or 1.024 V Voltage Output
Integral and Differential Linearity Guaranteed over Temperature
0.3" "Skinny DIP" Packaging
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD668 is an ultrahigh speed, 12-bit, multiplying digital-to-analog converter, providing outstanding accuracy and speed performance in responding to both analog and digital inputs. The AD668 provides a level of performance and functionality in a monolithic device that exceeds that of many contemporary hybrid devices. The part is fabricated using Analog Devices' Complementary Bipolar (CB) Process, which features vertical NPN and PNP devices on the same chip without the use of dielectric isolation. The AD668's design capitalizes on this proprietary process in combination with standard low impedance circuit techniques to provide its unique combination of speed and accuracy in a monolithic part.

The wideband reference input is buffered by a high gain, closed loop reference amplifier. The reference input is essentially a 1 V, high impedance input, but trimmed resistive dividers are provided to readily accommodate 5 V and 1.25 V references. The reference amplifier features an effective small signal bandwidth of 15 MHz and an effective slew rate of 3% of full scale/ns.

Multiple matched current sources and thin film ladder techniques are combined to produce bit weighting. The output range can nominally be taken as a 10.24 mA current output or a 1.024 V voltage output. Varying the analog input can provide modulation of the DAC full scale from 10% to 120% of its nominal value. Bipolar outputs can be realized through pin-strapping to provide two-quadrant operation without additional external circuitry.

Laser wafer trimming insures full 12-bit linearity and excellent gain accuracy. All grades of the AD668 are guaranteed monotonic over their full operating temperature range. Furthermore, the output resistance of the DAC is trimmed to 100 Ω ± 1.0%.

The AD668 is available in four performance grades. The AD668JQ and KQ are specified for operation from 0°C to +70°C, the AD668AQ is specified for operation from −40°C to +85°C, and the AD668SQ specified for operation from −55°C to +125°C. All grades are available in a 24-pin cerdip (0.3" package.

PRODUCT HIGHLIGHTS

1. The fast settling time of the AD668 provides suitable performance for waveform generation, graphics display, and high-speed A/D conversion applications.
2. The high bandwidth reference channel allows high frequency modulation between analog and digital inputs.
3. The AD668's design is configured to allow wide variation of the analog input, from 10% to 120% of its nominal value.
4. The AD668's combination of high performance and tremendous flexibility makes it an ideal building block for a variety of high speed, high accuracy instrumentation applications.
5. The digital inputs are readily compatible with both TTL and 5V CMOS logic families.
6. Skinny DIP (0.3") packaging minimizes board space requirements and eases layout considerations.
7. The AD668 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD668/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

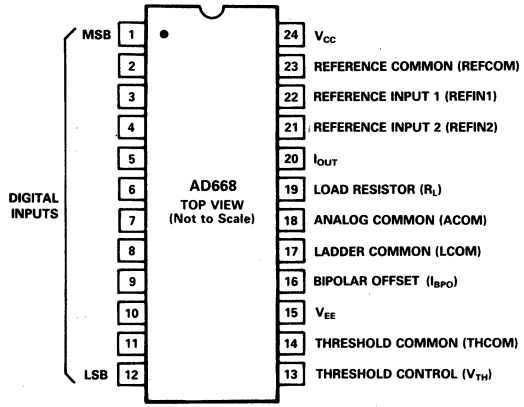
PIN CONFIGURATION



DEFINITIONS

LINEARITY ERROR (also called INTEGRAL NONLINEARITY OR INL): Analog Devices defines linearity error as the maximum deviation of the actual analog output from the ideal output (a straight line drawn from 0 to FS) for any bit combination expressed in multiples of 1 LSB. The AD668 is laser trimmed to 1/4 LSB (0.006% of FS) maximum linearity error at +25°C for the K version and 1/2 LSB for the J and S versions.

DIFFERENTIAL LINEARITY ERROR (also called DIFFERENTIAL NONLINEARITY or DNL): DNL is the measure of the variation in the analog output, normalized to full scale, associated with a 1 LSB change in digital input code.

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant as the digital input increases. Monotonic behavior requires that the differential linearity error not exceed 1 LSB in the negative direction.

UNIPOLAR OFFSET ERROR (DAC OFFSET): The DAC offset is the portion of the DAC output that is independent of the digital input. The unipolar DAC offset error is measured as the deviation of the analog output from the ideal (0 V or 0 mA) when the analog input is set to 100% and the digital inputs are set to all 0s.

BIPOLAR OFFSET ERROR: The deviation of the analog output from the ideal (negative half-scale) when the DAC is connected in the bipolar mode (Pin 16 connected to Pin 20), the analog input is set to 100%, and the digital inputs are set to all 0s is called the bipolar offset error.

BIPOLAR ZERO ERROR: The deviation of the analog output from the ideal (0 V or 0 mA) for bipolar mode when only the MSB is on (100 . . . 00) is called bipolar zero error.

COMPLIANCE VOLTAGE: The allowable voltage excursion at the output node of a DAC which will not degrade the accuracy of the DAC output.

SETTLING TIME (DIGITAL CHANNEL): The time required for the output to reach and remain within a specified error band about its final value, measured from the digital input transition.

SETTLING TIME (ANALOG CHANNEL): The time required for the output to reach and remain within a specified error band about its final value, measured from the analog input's crossing of it's 50% value.

GAIN ERROR: The difference between the ideal and actual output span of FS−1 LSB, expressed either in % of FS or LSB, when all bits are on is called the gain error.

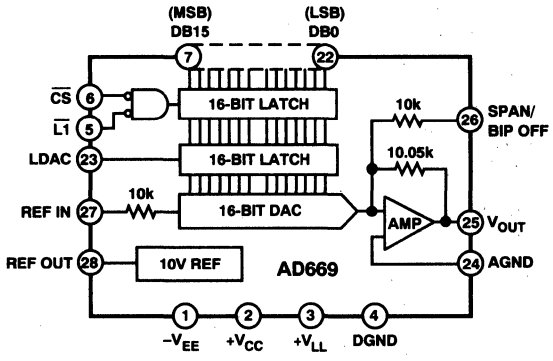
Monolithic 16-Bit DACPORT

AD669

FEATURES

Complete 16-Bit D/A Function
On-Chip Output Amplifier
High Stability Buried Zener Reference
Monolithic BiMOS II Construction
±1 LSB Integral Linearity Error
15-Bit Monotonic over Temperature
Microprocessor Compatible
16-Bit Parallel Input
Double-Buffered Latches
Fast 40 ns Write Pulse
Unipolar or Bipolar Output
Low Glitch: 15 nV-s
Low THD+N: 0.009%
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD669 DACPORT® is a complete 16-bit monolithic D/A converter with an on-board reference and output amplifier. It is manufactured on Analog Devices' BiMOS II process. This process allows the fabrication of low power CMOS logic functions on the same chip as high precision bipolar linear circuitry. The AD669 chip includes current switches, decoding logic, an output amplifier, a buried Zener reference and double-buffered latches.

The AD669's architecture insures 15-bit monotonicity over temperature. Integral nonlinearity is maintained at ±0.003%, while differential nonlinearity is ±0.003% max. The on-chip output amplifier provides a voltage output settling time of 10 μs to within 1/2 LSB for a full-scale step.

Data is loaded into the AD669 in a parallel 16-bit format. The double-buffered latch structure eliminates data skew errors and provides for simultaneous updating of DACs in a multi-DAC system. Three TTL/LSTTL/5 V CMOS compatible signals control the latches: $\overline{CS}$, $\overline{LI}$ and LDAC.

The output range of the AD669 is pin programmable and can be set to provide a unipolar output range of 0 V to +10 V or a bipolar output range of −10 V to +10 V.

The AD669 is available in seven grades: AN and BN versions are specified from −40°C to +85°C and are packaged in a 28-pin plastic DIP. The AR and BR versions are specified for −40°C to +85°C operation and are packaged in a 28-pin SOIC. The SQ version is specified from −55°C to +125°C and is packaged in a hermetic 28-pin cerdip package. The AD669 is also available compliant to MIL-STD-883. Refer to the AD669/883B data sheet for specifications and test conditions.

DACPORT is a registered trademark of Analog Devices, Inc.

PRODUCT HIGHLIGHTS

1. The AD669 is a complete voltage output 16-bit DAC with voltage reference and digital latches on a single IC chip.
2. The internal buried Zener reference is laser trimmed to 10.000 volts with a ±0.2% maximum error. The reference voltage is also available for external applications.
3. The AD669 is both dc and ac specified. DC specs include ±1 LSB INL error and ±1 LSB DNL error. AC specs include 0.009% THD+N and 83 dB SNR. The ac specifications make the AD669 suitable for signal generation applications.
4. The double-buffered latches on the AD669 eliminate data skew errors while allowing simultaneous updating of DACs in multi-DAC systems.
5. The output range is a pin-programmable unipolar 0 V to +10 V or bipolar −10 V to +10 V output. No external components are necessary to set the desired output range.
6. The AD669 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD669/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]For 16-bit resolution, 1 LSB = 0.0015% of FSR = 15 ppm of FSR. For 15-bit resolution, 1 LSB = 0.003% of FSR = 30 ppm of FSR. For 14-bit resolution 1 LSB = 0.006% of FSR = 60 ppm of FSR. FSR stands for Full-Scale Range and is 10 V for a 0 to +10 V span and 20 V for a −10 V to +10 V span.

[2]Gain error and gain drift measured using the internal reference. Gain drift is primarily reference related. See the Using the AD669 with the AD688 Reference section for further information.

[3]External current is defined as the current available in addition to that supplied to REF IN and SPAN/BIPOLAR OFFSET on the AD669.

[4]Operation on ±12 V supplies is possible using an external reference like the AD586 and reducing the output range. Refer to the Internal/External Reference Use section.

[5]Measured with fixed 50 Ω resistors. Eliminating these resistors increases the gain error by 0.25% of FSR (Unipolar mode) or 0.50% of FSR (Bipolar mode). Refer to the Analog Circuit Connections section.

*Same as AD669AN/AR specification.

ESD SENSITIVITY

The AD669 features input protection circuitry consisting of large transistors and polysilicon series resistors to dissipate both high-energy discharges (Human Body Model) and fast, low-energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD669 has been classified as a Class 2 device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' ESD Prevention Manual.

ABSOLUTE MAXIMUM RATINGS*

V_{CC} to AGND . . . . . −0.3 V to +17.0 V
V_{EE} to AGND . . . . . +0.3 V to −17.0 V

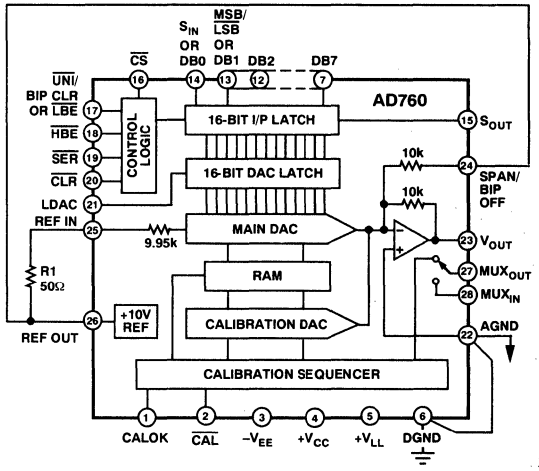
FEATURES

±0.00076% Integral and Differential Linearity
±0.00038% Unipolar Offset, Bipolar Zero
17-Bit Monotonic
Complete 16-Bit D/A Function
On-Chip Output Amplifier
On-Chip Buried Zener Voltage Reference
Microprocessor Compatible
Serial or Byte Input
Double Buffered Latches
Fast (40 ns) Write Pulse
Asynchronous Clear (to 0 V) Function
Serial Output Pin Facilitates Daisy Chaining
Pin Strappable Unipolar or Bipolar Output
Low Glitch: 15 nV-sec
Low THD+N: 0.009%
Output Control on Power-Up & Power-Down

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD760 is a complete 16-bit self-calibrating monolithic DAC (DACPORT®) with onboard voltage reference, double buffered latches and output amplifier. It is manufactured on Analog Devices' BiMOS II process. This process allows the fabrication of low power CMOS logic functions on the same chip as high precision bipolar linear circuitry.

Self-calibration is initiated by simply bringing the $\overline{CAL}$ pin low. The CALOK pin indicates when calibration has been successfully completed. The output multiplexer (MUX_{OUT}) can be used to isolate the load from the movement of the DAC output during calibration. The INL and DNL errors are less than ±0.5 LSB or ±0.00076% after calibration. Unipolar offset or bipolar zero is less than ±0.25 LSB or ±0.00038%. This level of performance is unmatched by any other monolithic DAC.

Data can be loaded into the AD760 in serial mode or as two 8-bit bytes. This is made possible by two digital input pins which have dual functions (Pins 13 and 14). The serial mode input format is pin selectable, to be MSB or $\overline{LSB}$ first. In byte mode the user can similarly define whether the high byte or low byte is loaded first. The serial output (S_{OUT}) pin allows the user to daisy chain several AD760s by shifting the data through the input latch into the next DAC thus minimizing the number of control lines required in a multiple DAC application. The double buffered latch structure eliminates data skew errors and provides for simultaneous updating of DACs in a multi-DAC system.

The asynchronous $\overline{CLR}$ function can be configured to clear the output to unipolar or bipolar zero depending on the state of LBE (another dual-use pin) when $\overline{CLR}$ is strobed. The AD760 also powers up or down with the output in a predetermined state by means of a digital and analog power supply detection circuit which is built in to the output multiplexer. This is particularly useful for robotic and industrial control applications.

The AD760 is available in three grades. AN and AP versions are specified from −40°C to +85°C and are packaged in a 28-pin 600 mil plastic DIP and a 28-pin PLCC. The SD version is packaged in a 28-pin 600 mil cerdip package and is also available compliant to MIL-STD-883. Refer to the AD760/883B data sheet for specifications and test conditions.

DACPORT is a registered trademark of Analog Devices, Inc.

PRODUCT HIGHLIGHTS

1. Complete, true 16-bit, self-calibrating DAC, with a voltage reference, double-buffered latches and output amplifier on a single chip.
2. Pin programmable output can provide a unipolar output range of 0 V to +10 V or a bipolar output range of −10 V to +10 V. No external components required.
3. Asynchronous $\overline{CLR}$ function can send the output to unipolar or bipolar zero.
4. MUX_{OUT} is switched to a user defined input when powering up or down.
5. The AD760 is both dc and ac specified. DC specifications include ±0.5 LSB INL and DNL errors. AC specifications include 0.009% THD+N and 83 dB SNR.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]For 16-bit resolution, 1 LSB = 0.0015% of FSR. For 15-bit resolution, 1 LSB = 0.003% of FSR. For 14-bit resolution, 1 LSB = 0.006% of FSR. FSR stands for full-scale range and is 10 V in unipolar mode and 20 V in bipolar mode.
[2]Characteristics are guaranteed at V_{OUT} Pin (23).
[3]T_{CAL} is the calibration temperature.
[4]Gain Error is measured with a fixed 50 Ω resistor as shown in Figure 4a and Figure 5a.
[5]Gain Error and gain drift are measured with the internal reference. The internal reference is the main contributor to the gain drift. If lower drift is required the AD760 can be used with a precision external reference such as the AD587, AD586 or AD688.
[6]DAC Gain Error is measured without the on-chip voltage reference. It represents the performance that can be obtained with an external precision reference.
[7]External current is defined as the current available in addition to that supplied to REF IN and SPAN/BIPOLAR OFFSET on the AD760.
[8]Operation on ±12 V supplies is possible using an external reference such as the AD586 and reducing the output range. Refer to the Internal/External Reference section.
*Indicates that the specification is the same as the AD760AN.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD760 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

ABSOLUTE MAXIMUM RATINGS*

V_{CC} to AGND . . . . . −0.3 V to +17.0 V
V_{EE} to AGND . . . . . +0.3 V to −17.0 V

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

DEFINITIONS OF SPECIFICATIONS

INTEGRAL NONLINEARITY: Analog Devices defines integral nonlinearity as the maximum deviation of the actual, adjusted DAC output from the ideal analog output (a straight line drawn from 0 to FS–1 LSB) for any bit combination. This is also referred to as relative accuracy.

DIFFERENTIAL NONLINEARITY: Differential nonlinearity is the measure of the change in the analog output, normalized to full scale, associated with a 1 LSB change in the digital input code. Monotonic behavior requires that the differential linearity error be greater than or equal to −1 LSB over the temperature range of interest.

MONOTONICITY: A DAC is monotonic if the output either increases or remains constant for increasing digital inputs with the result that the output will always be a single-valued function of the input.

GAIN ERROR: Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been adjusted out.

OFFSET ERROR: Offset error is a combination of the offset errors of the voltage-mode DAC and the output amplifier and is measured with all 0s loaded in the DAC.

BIPOLAR ZERO ERROR: When the AD760 is connected for bipolar output and 10 . . . 000 is loaded in the DAC, the deviation of the analog output from the ideal midscale value of 0 V is called the bipolar zero error.

DRIFT: Drift is the change in a parameter (such as gain, offset and bipolar zero) over a specified temperature range. The drift temperature coefficient, specified in ppm/°C, is calculated by measuring the parameter at T_{MIN}, 25°C and T_{MAX} and dividing the change in the parameter by the corresponding temperature change.

TOTAL HARMONIC DISTORTION + NOISE: Total harmonic distortion + noise (THD+N) is defined as the ratio of the square root of the sum of the squares of the values of the harmonics and noise to the value of the fundamental input frequency. It is usually expressed in percent (%).

THD+N is a measure of the magnitude and distribution of linearity error, differential linearity error, quantization error and noise. The distribution of these errors may be different, depending upon the amplitude of the output signal. Therefore, to be the most useful, THD+N should be specified for both large and small signal amplitudes.

SIGNAL-TO-NOISE RATIO: The signal-to-noise ratio is defined as the ratio of the amplitude of the output when a full-scale signal is present to the output with no signal present. This is measured in dB.

DIGITAL-TO-ANALOG GLITCH IMPULSE: This is the amount of charge injected from the digital inputs to the analog output when the inputs change state. This is measured at half scale when the DAC switches around the MSB and as many as possible switches change state, i.e., from 011 . . . 111 to 100 . . . 000.

DIGITAL FEEDTHROUGH: When the DAC is not selected (i.e., $\overline{CS}$ is held high), high frequency logic activity on the digital inputs is capacitively coupled through the device to show up as noise on the V_{OUT} pin. This noise is digital feedthrough.

THEORY OF OPERATION

The AD760 uses autocalibration circuitry to produce a true 16-bit DAC with less than 0.5 LSB Integral and Differential Linearity Error and 0.25 LSB Offset Error. The block diagram in Figure 2 shows the circuit components needed for calibration.

The MAIN DAC uses an array of bipolar current sources with MOS current steering switches to develop a current proportional to the applied digital word, ranging from 0 to 2 mA. A segmented architecture is used, where the most significant four data bits are thermometer decoded to drive 15 equal current sources. The lesser bits are scaled using a R-2R ladder, then applied together with the segmented sources at the summing node of the output amplifier. An extra LSB is added to the MAIN DAC, for use during calibration.

The self calibration architecture of the AD760 attempts to reduce the linearity errors of its transfer function. The algorithm measures and removes the carry errors (DNL errors) associated with the upper 64 codes, including the zero offset.

In normal operation the top six bits of a code entering the MAIN DAC simultaneously address the RAM, calling up a correction code which is then applied to the CALDAC. The output currents of both the MAIN DAC and CALDAC are combined in the summing amplifier to produce the corrected output voltage.

In the first step of calibration the output of the MAIN DAC is set to the code just below the code to be calibrated. The extra LSB in the MAIN DAC is turned on to find the extrapolated value for the next code. The comparator is then nulled using the TRANSFER STD DAC. The voltage at V_{OUT} has in effect been sampled at the code to be calibrated.

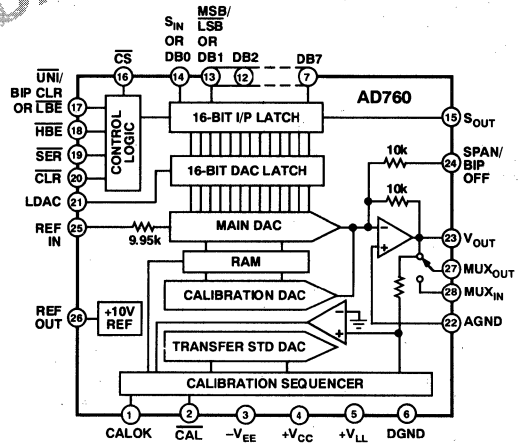

Figure 2. Functional Block Diagram

Next, the extra LSB is turned off and the MAIN DAC code is incremented by one LSB. The comparator is once again nulled, this time with the CALDAC, until the V_{OUT} is adjusted to equal the previously sampled output. The CALDAC code is stored in RAM and the process is repeated for the next code.

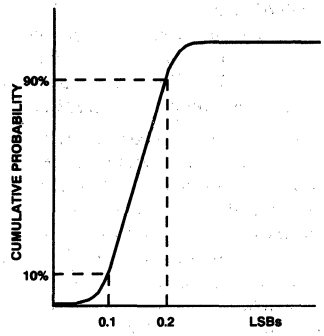

Figure 3. INL Statistics

Calibration repeatability is limited by thermal noise and the finite resolution of the two adjusting DACs. Over many recalibrations the AD760 will produce less than 0.2 LSB of peak INL for 90% of calibrations (0.5 LSB at a 30 ppm reject rate). A cumulative probability plot of the peak INL is shown in Figure 3.

ANALOG CIRCUIT CONNECTIONS

Internal scaling resistors provided in the AD760 may be connected to produce a unipolar output range of 0 V to +10 V or a bipolar output range of −10 V to +10 V. Gain and offset drift are minimized in the AD760 because of the thermal tracking of the scaling resistors with other device components.

UNIPOLAR CONFIGURATION

The configuration shown in Figure 4a will provide a unipolar 0 V to +10 V output range. In this mode a 50 Ω resistor is tied between REF OUT (Pin 26) and REF IN (Pin 25). It is possible to use the AD760 without any external components by tying Pin 26 directly to Pin 25. Eliminating this resistor will increase the gain error by 0.50% of FSR.

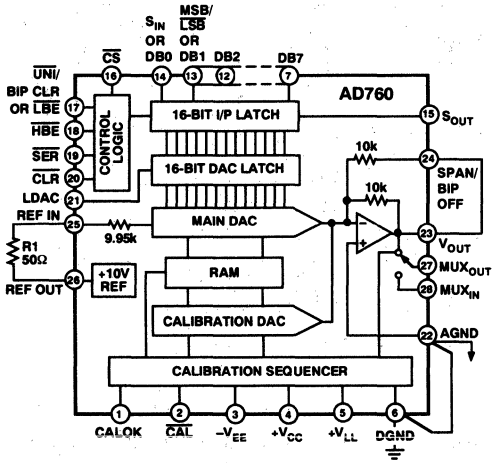

Figure 4a. 0 V to +10 V Unipolar Voltage Output

If it is desired to adjust the gain error to zero, this can be accomplished using the circuit shown in Figure 4b. The adjustment procedure is as follows:

STEP1 . . . ZERO ADJUST

Initiate calibration sequence. CALOK (Pin 1) must remain high throughout Gain Adjust.

STEP 2 . . . GAIN ADJUST

Turn all bits ON and adjust gain trimmer, R1, until the output is 9.999847 volts. (Full scale is adjusted to 1 LSB less than the nominal full scale of 10.000000 volts).

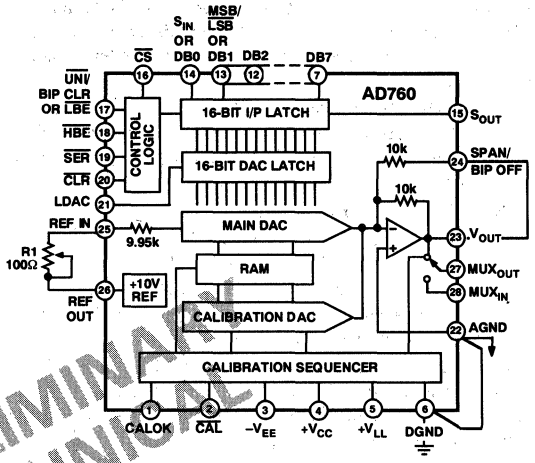

Figure 4b. 0 V to +10 V Unipolar Voltage Output with Gain Adjust

BIPOLAR CONFIGURATION

The circuit shown in Figure 5a will provide a bipolar output voltage from −10.000000 V to +9.999694 V with positive full scale occurring with all bits ON. As in the unipolar mode, resistor R1 may be eliminated altogether to provide AD760 bipolar operation without any external components. Eliminating this resistor will increase the gain error by 0.50% of FSR in the bipolar mode.

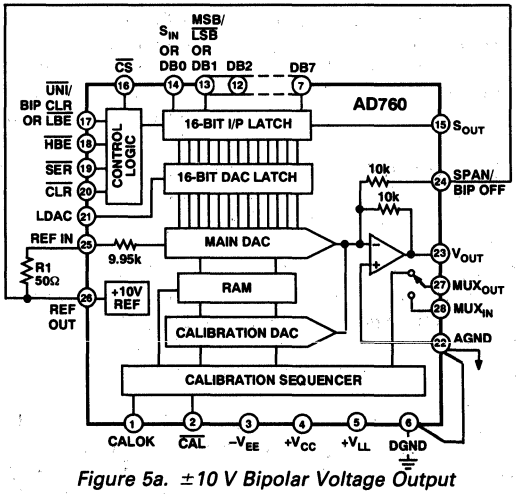

Figure 5a. ±10 V Bipolar Voltage Output

Gain Error can be adjusted to zero using the circuit shown in Figure 5b.

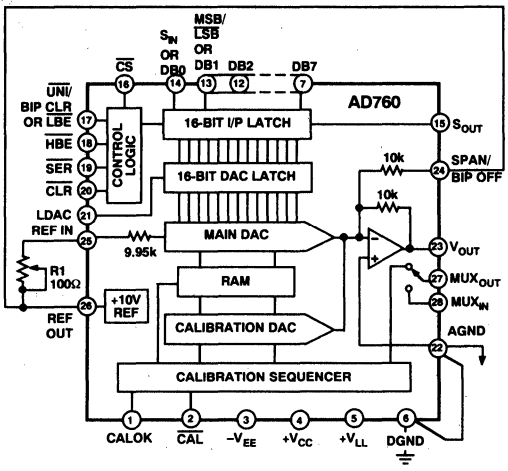

Figure 5b. ±10 V Bipolar Voltage Output Gain Adjustment

It should be noted that using external resistors will introduce a small temperature drift component beyond that inherent in the AD760. The internal resistors are trimmed to ratio-match and temperature-track other resistors on chip, even though their absolute tolerances are ±20% and absolute temperature coefficients are approximately −50 ppm/°C. In the case that external resistors are used, the temperature coefficient mismatch between internal and external resistors, multiplied by the sensitivity of the circuit to variations in the external resistor value, will be the resultant additional temperature drift.

INTERNAL/EXTERNAL REFERENCE USE

The AD760 has an internal low noise buried Zener diode reference which is trimmed for absolute accuracy and temperature coefficient. This reference is buffered and optimized for use in a high speed DAC and will give long-term stability equal or superior to the best discrete Zener diode references. The performance of the AD760 is specified with the internal reference driving the DAC and with the DAC alone (for use with a precision external reference).

The internal reference has sufficient buffering to drive external circuitry in addition to the reference currents required for the DAC (typically 1 mA to REF IN and 1 mA to BIPOLAR OFFSET). A minimum of 2 mA is available for driving external loads. The AD760 reference output should be buffered with an external op amp if it is required to supply more than 4 mA total current. The reference is tested and guaranteed to ±0.2% max error.

It is also possible to use external references other than 10 volts with slightly degraded linearity specifications. The recommended range of reference voltages is +5 V to +10.24 V, which allows 5 V, 8.192 V and 10.24 V ranges to be used. For example, by using the AD586 5 V reference, outputs of 0 V to +5 V unipolar or ±5 V bipolar can be realized. Using the AD586 voltage reference makes it possible to operate the AD760 with ±12 V supplies with 10% tolerances.

Figure 6 shows the AD760 using the AD586 precision 5 V reference in the bipolar configuration. The highest grade AD586MN is specified with a drift of 2 ppm/°C which is a 7.5× improvement over the AD760's internal reference. This circuit includes an optional potentiometer that can be used to adjust the gain error in a manner similar to that described in the BIPOLAR CONFIGURATION section. Use −5.000000 V and +4.999847 as the output values.

The AD760 can also be used with the AD587 10 V reference, using the same configuration shown in Figure 6 to produce a ±10 V output. The highest grade AD587LR, N is specified at 5 ppm/°C, which is a 3× improvement over the AD760's internal reference.

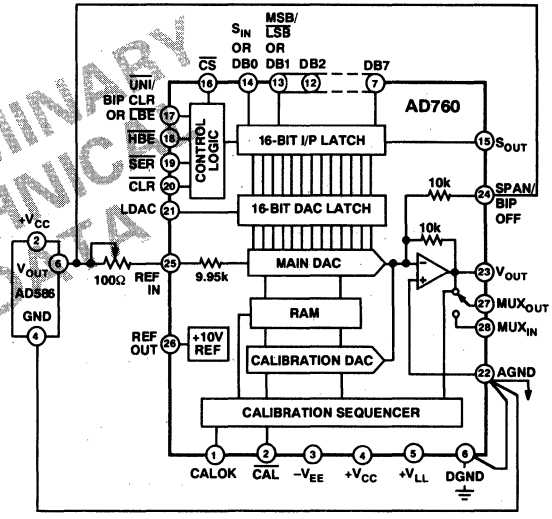

Figure 6. Using the AD760 with the AD586 5 V Reference

OUTPUT SETTLING AND GLITCH

The AD760's output buffer amplifier typically settles to within 0.0008% FS (1/2 LSB) of its final value in 8 μs for a full-scale step. Figures 7a and 7b show settling for a full-scale and an LSB step, respectively, with a 2 kΩ, 1000 pF load applied. The guaranteed maximum settling time at +25°C for a full-scale step is 13 μs with this load. The typical settling time for a 1 LSB step is 2.5 μs.

The digital-to-analog glitch impulse is specified as 15 nV-s typical. Figure 7c shows the typical glitch impulse characteristic at the code 011 . . . 111 to 100 . . . 000 transition when loading the second rank register from the first rank register.

Figure 7. Output Characteristics

DIGITAL CIRCUIT DETAILS

The AD760 has several "dual-use" pins which allow flexible operation while maintaining the lowest possible pin count and consequently the smallest package size. The following information is useful when applying the AD760.

The AD760 uses an internal **Output Multiplexer** to disconnect the DAC output from MUX_{OUT} (Pin 27) when the device is uncalibrated or when a calibration sequence is in progress. At those times MUX_{OUT} is switched to MUX_{IN} (Pin 28) so the user can force a predetermined output voltage.

A **Power On-Reset** feature senses whenever any power supply is low enough to jeopardize the integrity of the calibration data in the RAM. At power-up or in the event of a power supply transient, CALOK (Pin 1) is low and the MUX_{OUT} pin is switched to MUX_{IN}.

Self-Calibration is initiated by bringing the $\overline{CAL}$ pin low. The CALOK pin will go low and the MUX_{OUT} pin is connected to MUX_{IN}. After successful completion of calibration CALOK will go high and MUX_{OUT} is switched to V_{OUT}. The status of the calibration may be determined by taking the $\overline{HBE}$ pin low. CALOK either switches high if the calibration is in progress or CALOK remains low if a power supply voltage transient caused the AD760 to be set to the uncalibrated state.

Serial Mode Operation is enabled by bringing the $\overline{SER}$ (Pin 19) low. All unused data bits, DB2–DB7 must be tied low. This changes the function of DB0 (Pin 14) to that of the serial input pin, SIN. It also changes the function of DB1 (Pin 13) to a control input, MSB/$\overline{LSB}$ that tells the AD760 which bit is going to be loaded first.

In serial mode the byte controls $\overline{HBE}$ (Pin 18) and $\overline{LBE}$ (Pin 17) are disabled, and Pin 17's function changes to control how the asynchronous clear function works: a low when $\overline{CLR}$ is strobed sends the DAC to unipolar zero, a high sends it to bipolar zero.

Data is clocked into the input shift register on the rising edge of $\overline{CS}$ as shown in Figure 1b. The data is then resident in the first rank latch and can be loaded into the DAC by taking the LDAC pin high. This will cause the DAC to change to the appropriate output value. The second rank latch controlled by LDAC is a Transparent latch. Changes in the first rank latch will be reflected in the DAC output immediately, as long as LDAC remains high.

It should be noted that the clear function clears the DAC latch but does not clear the first rank latch. Therefore, the data that was previously resident in the first rank latch can be reloaded by simply bringing LDAC high again. Alternatively, new data can be loaded into the first rank latch if desired.

The serial out pin (S_{OUT}) can be used to daisy chain several DACs together in multi-DAC applications to minimize the number of data lines required. The first rank latch simply acts like a 16-bit shift register, and repeated strobing of $\overline{CS}$ will shift the data out through S_{OUT} and into the next DAC. Each DAC in the chain will require its own LDAC signal unless all of the DACs are to be updated simultaneously.

Byte Mode Operation is enabled by setting $\overline{SER}$ high, which configures DB0–DB7 as data inputs. In this mode $\overline{HBE}$ and $\overline{LBE}$ are used to identify the data as either the high byte or the low byte of the 16-bit word. The user can load the data in either order into the first rank latch using the rising edge of the $\overline{CS}$ signal as shown in Figure 1a. The status of Pin 17, when $\overline{CLR}$ is strobed determines whether the AD760 clears to unipolar or bipolar zero. (But it can not be hardwired to the desired state, as in the serial mode.)

NOTE: $\overline{CS}$ and $\overline{CAL}$ are edge triggered. $\overline{HBE}$, $\overline{LBE}$, $\overline{CLR}$, $\overline{SER}$, and LDAC are level triggered.

AD760 TO MC68HC11 (SPI BUS) INTERFACE

The AD760 interface to the Motorola SPI (serial peripheral interface) is shown in Figure 8. The MOSI, SCK, and $\overline{SS}$ pins of the HC11 are respectively connected to the BIT0, $\overline{CS}$ and LDAC pins of the AD760. The $\overline{SER}$ pin of the AD760 is tied low causing the first rank latch to be transparent. The majority of the interfacing issues are taken care of in the software initialization. A typical routine such as the one shown below begins

by initializing the state of the various SPI data and control registers.

The most significant data byte (MSBY) is then retrieved from memory and processed by the SENDAT subroutine. The $\overline{SS}$ pin is driven low by indexing into the PORTD data register and clear Bit 5. This causes the 2nd rank latch of the AD760 to become transparent. The MSBY is then set to the SPI data register where it is automatically transferred to the AD760.

The HC11 generates the requisite 8 clock pulses with data valid on the rising edges. After the most significant byte is transmitted, the least significant byte (LSBY) is loaded from memory and transmitted in a similar fashion. To complete the transfer, the LDAC pin is driven high latching the complete 16-bit word into the AD760.

AD760 TO MICROWIRE INTERFACE

The flexible serial interface of the AD760 is also compatible with the National Semiconductor MICROWIRE* interface. The MICROWIRE interface is used on microcontrollers such as the COP400 and COP800 series of processors. A generic interface to the MICROWIRE interface is shown in Figure 9. The G1, SK, and SO pins of the MICROWIRE interface are respectively connected to the LDAC, $\overline{CS}$ and BIT0 pins of the AD760.

*MICROWIRE is a registered trademark of National Semiconductor.

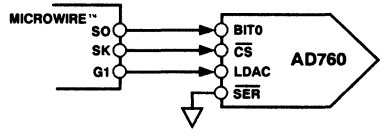

Figure 9. AD760 to MICROWIRE Interface

NOISE

In high resolution systems, noise is often the limiting factor. A 16-bit DAC with a 10 volt span has an LSB size of 153 μV (−96 dB). Therefore, the noise floor must remain below this level in the frequency range of interest. The AD760's noise spectral density is shown in Figures 10 and 11. Figure 12 shows the DAC output noise voltage spectral density for a 20 V span excluding the reference. This figure shows the 1/f corner frequency at 100 Hz and the wideband noise to be below 120 nV/$\sqrt{Hz}$. Figure 13 shows the reference noise voltage spectral density. This figure shows the reference wideband noise to be below 125 nV/$\sqrt{Hz}$.

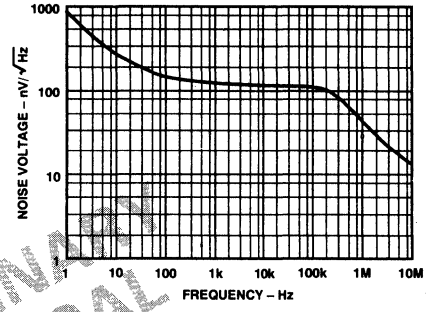

Figure 10. DAC Output Noise Voltage Spectral Density

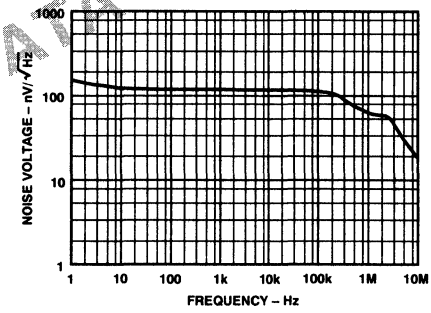

Figure 11. Reference Noise Voltage Spectral Density

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is the first issue. A 306 μA current through a 0.5 Ω trace will develop a voltage drop of 153 μV, which is 1 LSB at the 16-bit level for a 10 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals. Finally, power supplies need to be decoupled in order to filter out ac noise.

Analog and digital signals should not share a common path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes should also be used, with a single interconnection point to minimize ground loops. Analog signals should be routed as far as possible from digital signals and should cross them at right angles.

One feature that the AD760 incorporates to help the user layout is that the analog pins (V_{CC}, V_{EE}, REF OUT, REF IN, SPAN/ BIP OFFSET, V_{OUT}, MUX_{OUT}, MUX_{IN} and AGND) are adjacent to help isolate analog signals from digital signals.

SUPPLY DECOUPLING

The AD760 power supplies should be well filtered, well regulated, and free from high frequency noise. Switching power supplies are not recommended due to their tendency to generate spikes which can induce noise in the analog system.

Decoupling capacitors should be used in very close layout proximity between all power supply pins and ground. A 10 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor provides adequate decoupling. V_{CC} and V_{EE} should be bypassed to analog ground, while V_{LL} should be decoupled to digital ground.

An effort should be made to minimize the trace length between the capacitor leads and the respective converter power supply and common pins. The circuit layout should attempt to locate the AD760, associated analog circuitry and interconnections as far as possible from logic circuitry. A solid analog ground plane around the AD760 will isolate large switching ground currents. For these reasons, the use of wire wrap circuit construction is not recommended; careful printed circuit construction is preferred.

GROUNDING

The AD760 has two pins, designated analog ground (AGND) and digital ground (DGND.) The analog ground pin is the "high quality" ground reference point for the device. Any external loads on the output of the AD760 should be returned to analog ground. If an external reference is used, this should also be returned to the analog ground.

If a single AD760 is used with separate analog and digital ground planes, connect the analog ground plane to AGND and the digital ground plane to DGND keeping lead lengths as short as possible. Then connect AGND and DGND together at the AD760. If multiple AD760s are used or the AD760 shares analog supplies with other components, connect the analog and digital returns together once at the power supplies rather than at each chip. This single interconnection of grounds prevents large ground loops and consequently prevents digital currents from flowing through the analog ground.

ANALOG DEVICES

16-Bit DSP DACPORT

AD766

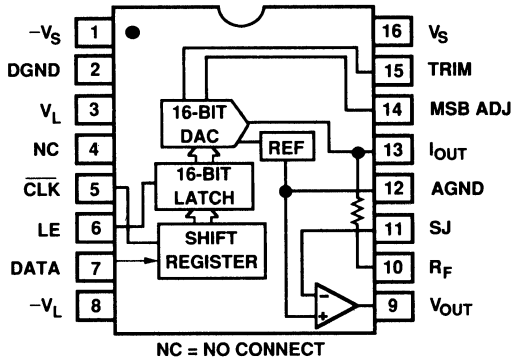
FEATURES

Zero-Chip Interface to Digital Signal Processors
Complete DACPORT®
On-Chip Voltage Reference
Voltage and Current Outputs
Serial, Twos-Complement Input
±3 V Output
Sample Rates to 390 kSPS
94 dB Minimum Signal-to-Noise Ratio
–81 dB Maximum Total Harmonic Distortion
15-Bit Monotonicity
±5 V to ±12 V Operation
16-Pin Plastic and Ceramic Packages
Available in Commercial, Industrial, and Military Temperature Ranges

APPLICATIONS

Digital Signal Processing
Noise Cancellation
Radar Jamming
Automatic Test Equipment
Precision Industrial Equipment
Waveform Generation

FUNCTIONAL BLOCK DIAGRAM



NC = NO CONNECT

PRODUCT DESCRIPTION

The AD766 16-bit DSP DACPORT provides a direct, three-wire interface to the serial ports of popular DSP processors, including the ADSP-2101, TMS320CXX, and DSP56001. No additional "glue logic" is required. The AD766 is also complete, offering on-chip serial-to-parallel input format conversion, a 16-bit current-steering DAC, voltage reference, and a voltage output op amp. The AD766 is fabricated in Analog Devices' BiMOS II mixed-signal process which provides bipolar transistors, MOS transistors, and thin-film resistors for precision analog circuits in addition to CMOS devices for logic.

The design and layout of the AD766 have been optimized for ac performance and are responsible for its guaranteed and tested 94 dB signal-to-noise ratio to 20 kHz and 79 dB SNR to 250 kHz. Laser-trimming the AD766's silicon chromium thin-film resistors reduces total harmonic distortion below −81 dB (at 1 kHz), a specification also production tested. An optional linearity trim pin allows elimination of midscale differential linearity error for even lower THD with small signals.

The AD766's output amplifier provides a ±3 V signal with a high slew rate, small glitch, and fast settling. The output amplifier is short circuit protected and can withstand indefinite shorts to ground.

The serial interface consists of bit clock, data, and latch enable inputs. The twos-complement data word is clocked MSB first on falling clock edges into the serial-to-parallel converter, consistent with the serial protocols of popular DSP processors. The input clock can support data transfers up to 12.5 MHz. The falling edge of latch enable updates the internal DAC input register at the sample rate with the sixteen bits most recently clocked into the serial input register.

The AD766 operates over a ±5 V to ±12 V power supply range. The digital supplies, $+V_L$ and $-V_L$, can be separated from the analog signal supplies, $+V_S$ and $-V_S$, for reduced digital crosstalk. Separate analog and digital ground pins are also provided. An internal bandgap reference provides a precision voltage source to the output amp that is stable over temperature and time.

Power dissipation is typically 120 mW with ±5 V supplies and 300 mW with ±12 V. The AD766 is available in commercial (0°C to 70°C), industrial (−40°C to 85°C), and military (−55°C to 125°C) grades. Commercial and industrial grade parts are available in a 16-pin plastic DIP; military parts processed to MIL-STD-883B are packaged in a 16-pin ceramic DIP. See Analog Devices' *Military Products Databook* or current military data sheet for specifications for the military version.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]For A grade only, voltage outputs are guaranteed only if $+V_S \geq 7$ V and $-V_S \leq -7$ V.
[2]Specified using external op amp, see Figure 3 for more details.
[3]Tested at full-scale input.
[4]For A grade only, power supplies must be symmetric, i.e., $V_S = |-V_S|$ and $+V_L = |-V_L|$. Each supply must independently meet this equality within ±5%.

All min and max specifications are guaranteed. Specifications in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels.

Specifications subject to change without notice.

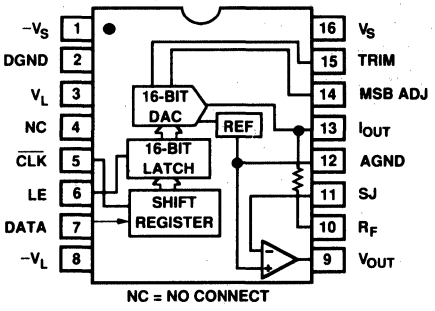
CONNECTION DIAGRAM



ESD SENSITIVITY

The AD766 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD766 has been classified as a Category 1 Device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment, and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam discharged to the destination socket before devices are removed. For further information on ESD precaution, refer to Analog Devices' *ESD Prevention Manual*.

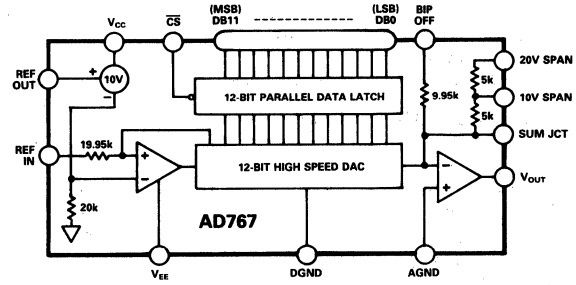
Microprocessor-Compatible 12-Bit D/A Converter

AD767*

FEATURES

- **Complete 12-Bit D/A Function**
  - **On-Chip Output Amplifier**
  - **High Stability Buried Zener Reference**
- **Fast 40ns Write Pulse**
- **0.3″ Skinny DIP and PLCC Packages**
- **Single Chip Construction**
- **Monotonicity Guaranteed Over Temperature**
- **Settling Time: 3μs max to 1/2LSB**
- **Guaranteed for Operation with ±12V or ±15V Supplies**
- **TTL/5V CMOS Compatible Logic Inputs**
- **MIL-STD-883 Compliant Versions Available**

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD767 is a complete voltage output 12-bit digital-to-analog converter including a high stability buried Zener reference and input latch on a single chip. The converter uses 12 precision high-speed bipolar current steering switches and a laser-trimmed thin-film resistor network to provide high accuracy.

Microprocessor compatibility is achieved by the on-chip latch. The design of the input latch allows direct interface to 12-bit buses. The latch responds to strobe pulses as short as 40ns, allowing use with the fastest available microprocessors.

The functional completeness and high performance of the AD767 result from a combination of advanced switch design, high-speed bipolar manufacturing process, and the proven laser wafer-trimming (LWT) technology.

The subsurface (buried) Zener diode on the chip provides a low-noise voltage reference which has long-term stability and temperature drift characteristics comparable to the best discrete reference diodes. The laser trimming process which provides the excellent linearity is also used to trim the absolute value of the reference as well as its temperature coefficient. The AD767 is thus well suited for wide temperature range performance with ±1/2LSB maximum linearity error and guaranteed monotonicity over the full temperature range. Typical full-scale gain T.C. is 5ppm/°C.

PRODUCT HIGHLIGHTS

1. The AD767 is a complete voltage output DAC with voltage reference and digital latches on a single IC chip.
2. The input latch responds to write pulse widths as short as 40ns assuring direct interface with the industry's fastest microprocessors.
3. The internal buried Zener reference is laser-trimmed to 10.00 volts with a ±1% maximum error. The reference voltage is also available for external application.
4. The gain setting and bipolar offset resistors are matched to the internal ladder network to guarantee a low gain temperature coefficient and are laser trimmed for minimum full-scale and bipolar offset errors.
5. The precision high-speed current steering switches and on-board high-speed output amplifier settle within 1/2LSB for a 10V full-scale transition in 3.0μs when properly compensated.
6. The AD767 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD767/883B data sheet for detailed specifications.

NOTES
[1]AD767 "S" specifications shown for information only. Consult Analog Devices Military Databook or contact factory for a controlled specification sheet.
[2]AD767A Chips specifications are tested at +25°C and, when in boldface, at +85°C. They are typical at −25°C.
[3]The digital input specifications are 100% tested at +25°C, and guaranteed but not tested over the full temperature range.
[4]Adjustable to zero.
[5]FSR means "Full-Scale Range" and is 20V for ±10V range and 10V for the ±5V range.
[6]A minimum power supply of ±12.5V is required for a ±10V full-scale output and ±11.4V is required for all other voltage ranges.
Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test (except per Notes 1 and 2). Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

ANALOG DEVICES

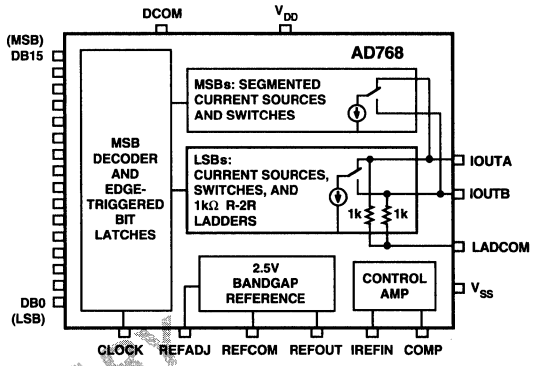
16-Bit, 32 MSPS Low Glitch D/A Converter

AD768

FEATURES

32 MSPS Update Rate
16-Bit Resolution
Linearity: 1 LSB DNL @ 14 Bits
1 LSB INL @ 14 Bits
Fast Settling: 25 ns Full-Scale Settling to 0.025%
SFDR @ 1 MHz Output: 80 dBc
Low Glitch Impulse: 60 pV-s
Power Dissipation: 500 mW
On-Chip 2.5 V Reference
Edge-Triggered Latches
CMOS Compatibility

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD768 is a 16-bit, high speed digital-to-analog converter (DAC) that offers exceptional ac and dc linearity. The AD768 is manufactured on Analog Devices' Advanced Bipolar CMOS (ABCMOS) process, combining the speed of bipolar transistors, the accuracy of laser trimmable thin-film resistors, and the efficiency of CMOS logic. A segmented current source architecture is combined with a proprietary switching technique to reduce glitch energy and maximize dynamic accuracy. Edge triggered input latches and a temperature compensated bandgap reference have been integrated to provide a complete monolithic DAC solution.

The AD768 is a current-output DAC with a nominal full-scale output current of 20 mA and a 1 kΩ output impedance. Differential current outputs are provided to support single-ended or differential applications. The current outputs may be tied directly to an output resistor to provide a voltage output, or fed to the summing junction of a high speed amplifier to provide a buffered voltage output.

The on-chip reference and control amplifer are configured for maximum accuracy and flexibility. The AD768 can be driven by the on-chip reference or by a variety of external reference voltages based on the selection of an external resistor. An external capacitor allows the user to optimally tradeoff reference bandwidth and noise performance.

The AD768 operates on ±5 V supplies, typically consuming 500 mW of power. The AD768 is available in a 28-pin SOIC package and is specified for operation over the industrial temperature range.

PRODUCT HIGHLIGHTS

1. The low glitch and fast settling time provide outstanding dynamic performance for waveform reconstruction or digital synthesis requirements, including communications.
2. The excellent dc accuracy of the AD768 makes it suitable for high speed A/D conversion applications.
3. On-chip, edge-triggered input CMOS latches interface readily to CMOS logic families. The AD768 can support update rates up to 32 Msps.
4. A temperature compensated, 2.5 V bandgap reference is included on-chip allowing for generation of the reference input current with the use of a single external resistor. An external reference may also be used.
5. The current output(s) of the AD768 may be used singly or differentially, either into a load resistor or external op amp summing junction.
6. Proper selection of an external resistor and compensation capacitor allow the performance-conscious user to optimize the AD768 reference level and bandwidth for the target application.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD768–SPECIFICATIONS (T_A = +25°C, V_{DD} = +5.0 V, V_{SS} = –5 V, LADCOM, REFCOM, DCOM = 0 V, IREFIN = 5 mA, CLOCK =10 MHz, unless otherwise noted)

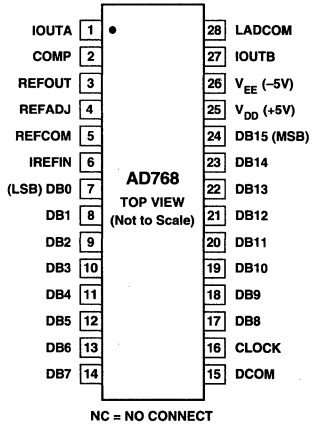
NOTE
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating for extended periods may affect device reliability.

PIN CONFIGURATION

28-PIN SOIC



NC = NO CONNECT

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD768 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN DESCRIPTION

Pin No.	Symbol	Type	Name and Function
1	IOUTA	AO	DAC Current Output. Full-scale current when all data bits are 1s.
2	COMP	AI	Compensation Node. Add capacitor for noise reduction.
3	REFOUT	AO	Reference Output Voltage. Nominal value is 2.5 V.
4	REFADJ	AI	Reference Adjust. Apply voltage from 0 to 2.5 V to adjust DAC gain.
5	REFCOM	P	Reference Ground.
6	IREFIN	AI	Reference Input Current. Nominal is 5 mA. DAC full-scale is 4× this current.
7	DB0	DI	Data Bit 0 (LSB).
8–14	DB1–7	DI	Data Bits 1–7.
15	DCOM	P	Digital Ground.
16	CLOCK	DI	Clock Input. Data latched on positive edge of clock.
17–23	DB8–DB14	DI	Data Bits 8–14.
24	DB15	DI	Data Bit 15 (MSB).
25	V_{DD}	P	Positive Supply Voltage. Nominal is +5 V.
26	V_{EE}	P	Negative Supply Voltage. Nominal is –5 V.
27	IOUTB	AO	Complementary DAC Current Output. Full-scale current when all data bits are 0s.
28	LADCOM	P	DAC Ladder Common.

Type: AI = Analog Input; DI = Digital Input; AO = Analog Output; P = Power

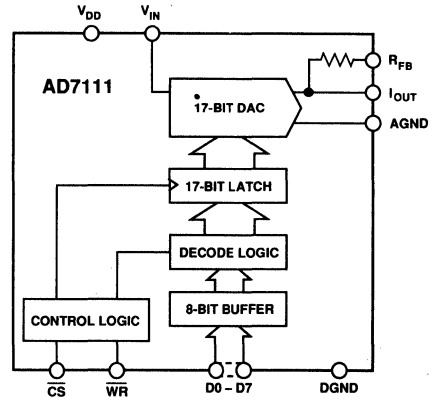
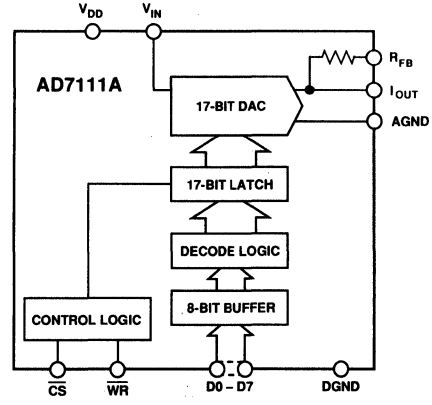
LC²MOS LOGDAC
Logarithmic D/A Converter
AD7111/AD7111A

FEATURES
Dynamic Range: 88.5 dB
Resolution: 0.375 dB
On-Chip Data Latches
+5 V Operation
AD7111A Pin Compatible with AD7524
Low Power

APPLICATIONS
Audio Attenuators
Sonar Systems
Function Generators
Digitally Controlled AGC System

FUNCTIONAL BLOCK DIAGRAMS





GENERAL DESCRIPTION

The LOGDAC® AD7111/AD7111A are monolithic multiplying D/A converters featuring wide dynamic range in a small package. Both DACs can attenuate an analog input signal over the range 0 dB to 88.5 dB in 0.375 dB steps. They are available in 16-pin DIPs and SOIC packages. The AD7111 is also available in a 20-terminal LCCC package.

The degree of attenuation across the DAC is determined by an 8-bit word applied to the on-board decode logic. This 8-bit word is decoded into a 17-bit word which is then applied to a 17-bit R-2R ladder. The very fine step resolution, which is available over the entire dynamic range, is due to the use of this 17-bit DAC.

The AD7111/AD7111A are easily interfaced to a standard 8-bit MPU bus via an 8-bit data port and standard microprocessor control lines. The AD7111 $\overline{WR}$ input is edge triggered and requires a rising edge to load new data to the DAC. The AD7111A $\overline{WR}$ is level triggered to allow transparent operation of the latches, if required. It should also be noted that the AD7111A is exactly pin and function-compatible with the AD7524, an industry standard 8-bit multiplying DAC. This allows an easy upgrading of existing AD7524 designs which would benefit both from the wider dynamic range and the finer step resolution offered by the AD7111A.

The AD7111/AD7111A are fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic.

PRODUCT HIGHLIGHTS

1. Wide Dynamic Range: 0 dB to 88.5 dB attenuation range in 0.375 dB steps.
2. Small Package: The AD7111/AD7111A are available in 16-pin DIPs and SOIC packages.
3. Transparent Latch Operation: By tying the $\overline{CS}$ and $\overline{WR}$ inputs low, the DAC latches in the AD7111A can be made transparent.
4. Fast Microprocessor Interface: Data setup times of 25 ns and write pulse width of 57 ns make the AD7111A compatible with modern microprocessors.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD SUSCEPTIBILITY

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 volts, which readily accumulate on the human body and on test equipment, can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper precautions are recommended to avoid any performance degradation or loss of functionality.

TERMINOLOGY

RESOLUTION: Nominal change in attenuation when moving between two adjacent codes.

MONOTONICITY: The device is monotonic if the analog output decreases (or remains constant) as the digital code increases.

FEEDTHROUGH ERROR: That portion of the input signal which reaches the output when all digital inputs are high. See section on Applications.

OUTPUT LEAKAGE CURRENT: Current which appears on the I_{OUT} terminal with all digital inputs high.

TOTAL HARMONIC DISTORTION: A measure of the harmonics introduced by the circuit when a pure sinusoid is applied to the input. It is expressed as the harmonic energy divided by the fundamental energy at the output.

ACCURACY: The difference (measured in dB) between the ideal transfer function as listed in Table I and the actual transfer function as measured with the device.

OUTPUT CAPACITANCE: Capacitance from I_{OUT} to ground.

DIGITAL-TO-ANALOG GLITCH IMPULSE: The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage signal. Glitch impulse is measured with V_{IN} = AGND.

PROPAGATION DELAY: This is a measure of the internal delays of the circuit and is defined as the time from a digital input change to the analog output current reaching 90% of its final value.

CIRCUIT DESCRIPTION

GENERAL CIRCUIT DESCRIPTION

The AD7111/AD7111A consists of a 17-bit R-2R CMOS multiplying D/A converter with extensive digital logic. The logic translates the 8-bit binary input into a 17-bit word which is used to drive the D/A converter. Input data on the D7–D0 bus is loaded into the input data latches using $\overline{CS}$ and $\overline{WR}$ control signals. When using the AD7111, the rising edge of $\overline{WR}$ latches the input data and initiates the internal data transfer to the decoder. A minimum time t_{RFSH}, the refresh time, is required for the data to propagate through the decoder before a new data write is attempted.

In contrast, the AD7111A $\overline{WR}$ input is level triggered to allow transparent operation of the latches if required.

The transfer function for the circuit of Figure 1 is given by:

$$V_O = -V_{IN}\ 10\ exp\ -\frac{0.375\ N}{20}$$

$$or\ \left|\frac{V_O}{V_{IN}}\right| dB = -0.375\ N$$

where 0.375 is the step size (resolution) in dB and N is the input code in decimal for values 0 to 239. For $240 \leq N \leq 255$ the output is zero. Table I gives the output attenuation relative to 0 dB for all possible input codes.

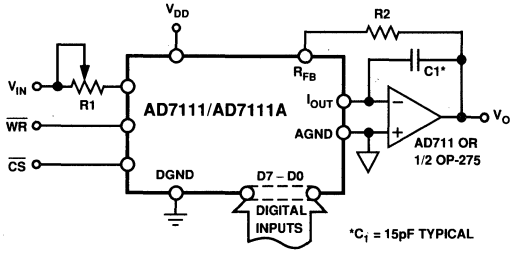

Figure 1. Typical Circuit Configuration

The graphs on the last page give a pictorial representation of the specified accuracy and monotonic ranges for all grades of the AD7111/AD7111A. High attenuation levels are specified with less accuracy than low attenuation levels. The range of monotonic behavior depends upon the attenuation step size used. For

example, the AD7111L is guaranteed monotonic in 0.375 dB steps from 0 dB to −54 dB inclusive and in 0.75 dB steps from 0 dB to −72 dB inclusive. To achieve monotonic operation over the entire 88.5 dB range it is necessary to select input codes so that the attenuation step size at any point is consistent with the step size guaranteed for monotonic operation at that point.

EQUIVALENT CIRCUIT ANALYSIS

Figure 2 shows a simplified circuit of the D/A converter section of the AD7111/AD7111A, and Figure 3 gives an approximate equivalent circuit.

The current source $I_{LEAKAGE}$ is composed of surface and junction leakages. The resistor R_0 as shown in Figure 3 is the equivalent output resistance of the device which varies with input code (excluding all 0s code) from 0.8R to 2R. R is typically 12 kΩ. C_{OUT} is the capacitance due to the N channel switches and varies from about 20 pF to 50 pF depending upon the digital input. For further information on CMOS multiplying D/A converters, refer to "CMOS DAC Application Guide" which is available from Analog Devices, Publication Number G872b–8–1/89.

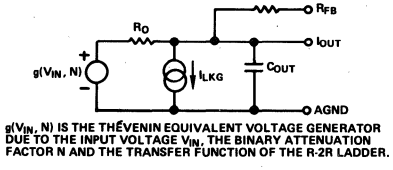

Figure 3. Equivalent Analog Output Circuit of AD7111/AD7111A

DYNAMIC PERFORMANCE

The dynamic performance of the AD7111/AD7111A will depend upon the gain and phase characteristics of the output amplifier, together with the optimum choice of PC board layout and decoupling components. Circuit layout is most important if the optimum performance of the AD7111/AD7111A is to be achieved. Most application problems stem from either poor layout, grounding errors, or inappropriate choice of amplifier.

It is recommended that when using the AD7111/AD7111A with a high speed amplifier, a capacitor (C1) be connected in the feedback path as shown in Figure 1. This capacitor, which should be between 10 pF and 30 pF, compensates for the phase lag introduced by the output capacitance of the D/A converter.

Figures 4 and 5 show the performance of the AD7111/AD7111A using the AD711, a high speed, low cost BiFET amplifier, and the OP-275, a dual, bipolar/JFET, audio amplifier. The performance without C1 is shown in the middle trace and the response with C1 in circuit shown in the bottom trace.

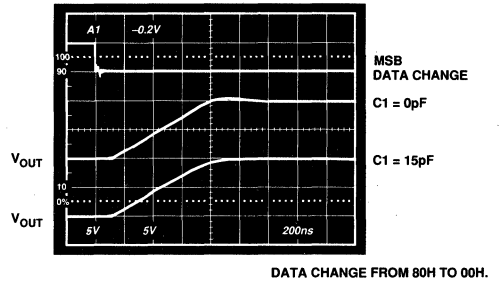

Figure 4. Response of AD7111/AD7111A with AD711

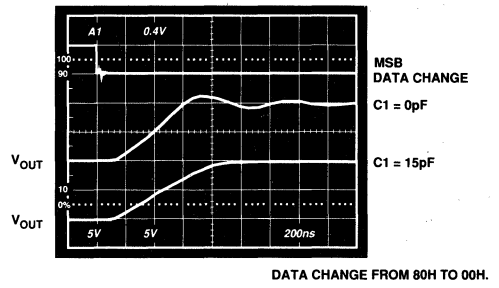

Figure 5. Response of AD7111/AD7111A with 1/2 OP-275

In conventional CMOS D/A converter design, parasitic capacitance in N-channel D/A converter switches can give rise to glitches on the D/A converter output. These glitches result from digital feedthrough. The AD7111/AD7111A has been designed to minimize these glitches as much as possible.

For operation beyond 250 kHz, capacitor C1 may be reduced in value. This gives an increase in bandwidth at the expense of a poorer transient response as shown in Figure 5. In circuits where C1 is not included, the high frequency roll-off point is primarily determined by the characteristics of the output amplifier and not the AD7111/AD7111A.

Feedthrough and absolute accuracy are sensitive to output leakage current effects. For this reason it is recommended that the operating temperature of the AD7111/AD7111A be kept as close to 25°C as is practically possible, particularly where the device's performance at high attenuation levels is important.

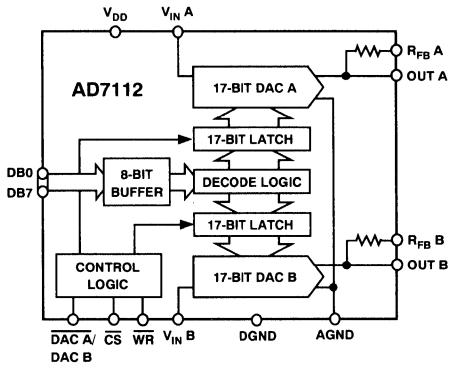
Some solder fluxes and cleaning materials can form slightly conductive films which cause leakage effects between analog input and output. The user is cautioned to ensure that the manufacturing process for circuits using the AD7111/AD7111A does not allow such films to form. Otherwise the feedthrough, accuracy and maximum usable range will be affected.

LC²MOS LOGDAC
Dual Logarithmic D/A Converter
AD7112*

FEATURES
Dynamic Range: 88.5 dB
Resolution: 0.375 dB
On-Chip Data Latches for Both DACs
Four-Quadrant Multiplication
+5 V Operation
Pin Compatible with AD7528
Low Power

APPLICATIONS
Audio Attenuators
Sonar Systems
Function Generators

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The LOGDAC® AD7112 is a monolithic dual multiplying D/A converter featuring wide dynamic range and excellent DAC-to-DAC matching. Both DACs can attenuate an analog input signal over the range 0 to 88.5 dB in 0.375 dB steps. It is available in skinny 0.3″ wide 20-pin DIPs and in 20-terminal surface mount packages.

The degree of attenuation in either channel is determined by the 8-bit word applied to the on-board decode logic. This 8-bit word is decoded into a 17-bit word which is then loaded into one of the 17-bit data latches, determined by $\overline{\text{DACA}}$/DACB. The fine step resolution over the entire dynamic range is due to the use of these 17-bit DACs.

The AD7112 is easily interfaced to a standard 8-bit MPU bus via an 8-bit data port and standard microprocessor control lines. It should be noted that the AD7112 is exactly pin-compatible with the AD7528, an industry standard dual 8-bit multiplying DAC. This allows an easy upgrading of existing AD7528 designs which would benefit both from the wider dynamic range and the finer step resolution offered by the AD7112.

The AD7112 is fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic.

***Protected by U.S. Patent No. 4521764**
LOGDAC is a registered trademark of Analog Devices, Inc.

PRODUCT HIGHLIGHTS

1. DAC-to-DAC Matching: Since both of the AD7112 DACs are fabricated at the same time on the same chip, precise matching and tracking between the two DACs is inherent.
2. Small Package: The AD7112 is available in a 20-pin DIP and a 20-terminal SOIC package.
3. Fast Microprocessor Interface: The AD7112 has bus interface timing compatible with all modern microprocessors.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

ESD SUSCEPTIBILITY

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 volts, which readily accumulate on the human body and on test equipment, can discharge without detection. Although devices feature proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper precautions are recommended to avoid any performance degradation or loss of functionality.

TERMINOLOGY

RESOLUTION: Nominal change in attenuation when moving between two adjacent codes.

MONOTONICITY: The device is monotonic if the analog output decreases or remains constant as the digital code increases.

FEEDTHROUGH ERROR: That portion of the input signal which reaches the output when all digital inputs are high.

OUTPUT CAPACITANCE: Capacitance from OUT A or OUT B to ground.

GAIN ERROR: Gain error results from a mismatch between R_{FB} (the feedback resistance) and the R–2R ladder resistance. Its effect in a LOGDAC is to produce a constant additive attenuation error in dB over the whole range of the DAC.

ACCURACY: The difference (measured in dB) between the ideal transfer function as listed in Table I and the actual transfer function as measured with the device.

DIGITAL-TO-ANALOG GLITCH IMPULSE: The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-s or nV-s depending on whether the glitch is measured as a current or voltage signal. Glitch impulse is measured with V_{IN} = AGND.

ORDERING GUIDE

Model	Temperature Range	Specified Accuracy Range	Package Option*
AD7112BN	−40°C to +85°C	0 dB to 60 dB	N-20
AD7112CN	−40°C to +85°C	0 dB to 72 dB	N-20
AD7112BR	−40°C to +85°C	0 dB to 60 dB	R-20
AD7112CR	−40°C to +85°C	0 dB to 72 dB	R-20

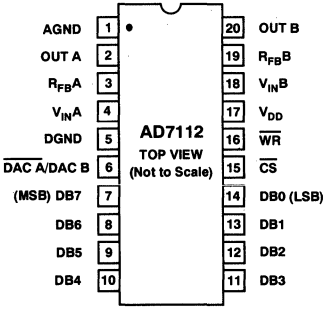
PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	AGND	Analog Ground.
2	OUT A	Current Output Terminal of DAC A.
3	R_{FB} A	Feedback Resistor for DAC A.
4	V_{IN} A	Reference Input to DAC A
5	DGND	Digital Ground.
6	$\overline{\text{DAC A}}$ / DAC B	Selects Which DAC Can Accept Data from Input Port.
7–14	DB7–DB0	8 Data Inputs.
15	$\overline{CS}$	Chip Select Input, Active Low.
16	$\overline{WR}$	Write Input, Active Low.
17	V_{DD}	Power Supply Input 5 V ± 5%.
18	V_{IN} B	Reference Input to DAC B.
19	R_{FB} B	Feedback Resistor for DAC B.
20	OUT B	Current Output Terminal of DAC B.

PIN CONFIGURATION DIP/SOIC



CIRCUIT DESCRIPTION

GENERAL CIRCUIT INFORMATION

The AD7112 consists of a dual 17-bit R–2R CMOS multiplying D/A converter with extensive digital logic. Figure 1 shows a simplified circuit of the D/A converter section of the AD7112. The logic translates the 8-bit binary input into a 17-bit word which is used to drive the D/A converter. Figure 2 shows a typical circuit configuration for the AD7112.

The transfer function for the circuit of Figure 2 is given by:

$$V_O = -V_{IN} \times 10\,exp\,-\frac{0.375\,N}{20}$$

or

$$\left|\frac{V_O}{V_{IN}}\right| dB = -0.375\,N$$

where 0.375 is the step size (resolution) in dB and N is the input code in decimal for values 0 to 239. For $240 \leq N \leq 255$ the output is zero. Table I gives the output attenuation relative to 0 dB for all possible input codes.

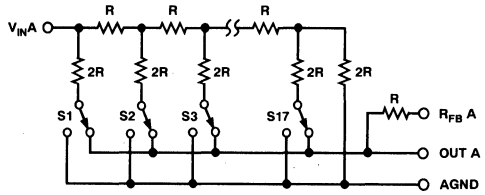


Figure 1. Simplified D/A Circuit of 1/2 AD7112

Figures 16 and 17 give a pictorial representation of the specified accuracy and monotonic ranges for all grades of the AD7112. High attenuation levels are specified with less accuracy than low attenuation levels. The range of monotonic behavior depends upon the attenuation step size used. To achieve monotonic operation over the entire 88.5 dB range, it is necessary to select input codes so that the attenuation step size at any point is consistent with the step size guaranteed for monotonic operation at that point.

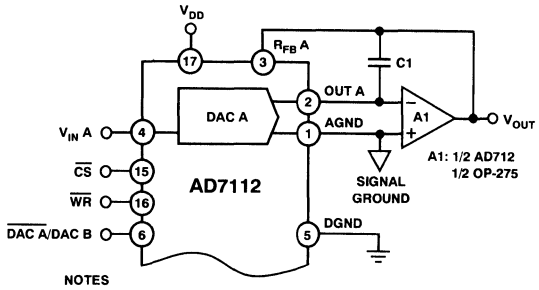

Figure 2. Typical Circuit Configuration

Table I. Ideal Attenuation in dB vs. Input Code

INTERFACE LOGIC INFORMATION

DAC Selection

Both DAC latches share a common 8-bit port. The control input $\overline{DAC\ A}$/DAC B selects which DAC can accept data from the input port.

Mode Selection

Inputs $\overline{CS}$ and $\overline{WR}$ control the operating mode of the selected DAC. See the Mode Selection Table below.

Write Mode

When $\overline{CS}$ and $\overline{WR}$ are both low the DAC is in the write mode. The input data latches of the selected DAC are transparent and its analog output responds to activity on DB0–DB7.

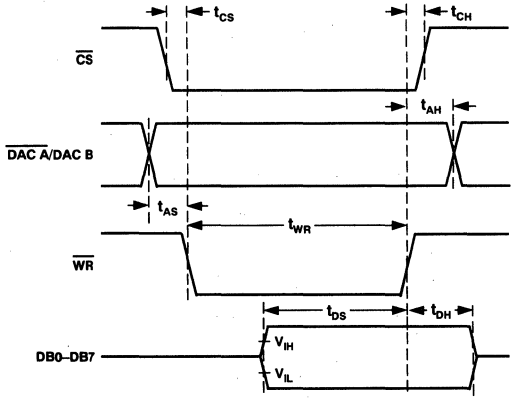
Hold Mode

The selected DAC latch retains the data which was present on DB0–DB7 just prior to $\overline{CS}$ and $\overline{WR}$ assuming a high state. Both analog outputs remain at the values corresponding to the data in their respective latches.

Mode Selection Table

$\overline{DAC\ A}$ / DAC B	$\overline{CS}$	$\overline{WR}$	DAC A	DAC B
L	L	L	WRITE	HOLD
H	L	L	HOLD	WRITE
X	H	X	HOLD	HOLD
X	X	H	HOLD	HOLD

L = Low State, V_{IL}; H = High State, V_{IH}; X = Don't Care.



NOTES
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% TO 90% OF V_{DD}. tR = tF = 20ns.
2. CONTROL TIMING MEASUREMENT REFERENCE LEVEL = $(V_{IH} + V_{IL}) / 2$

Figure 3. Write Cycle Timing Diagram

DYNAMIC PERFORMANCE

The dynamic performance of the AD7112 will depend on the gain and phase characteristics of the output amplifier, together with the optimum choice of PC board layout and decoupling components. Circuit layout is most important if the optimum performance of the AD7112 is to be achieved. Most application problems stem from either poor layout, grounding errors, or inappropriate choice of amplifier. Ensure that the layout of the printed circuit board has the digital and analog lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Establish a single point analog ground (star ground) separate from the logic system ground. Place this ground as close as possible to the AD7112. Connect all analog grounds to this star ground, and also connect the AD7112 DGND to this ground. Do not connect any other digital grounds to this analog ground point. Low impedance analog and digital power supply common returns are essential for low noise and high performance of these converters, therefore the foil width of these tracks should be as wide as possible. The use of ground planes is recommended as this minimizes impedance paths and also guards the analog circuitry from digital noise.

It is recommended that when using the AD7112 with a high speed amplifier, a capacitor (C1) be connected in the feedback path as shown in Figure 2. This capacitor which should be between 5 pF and 15 pF, compensates for the phase lag introduced by the output capacitance of the D/A converter. Figures 4 and 5 show the performance of the AD7112 using the AD712, a high speed, low cost BIFET amplifier, and the OP-275, a dual bipolar/JFET amplifier suitable for audio applications. The performance with and without the compensation capacitor is shown in both cases. For operation beyond 250 kHz, capacitor C1 may be reduced in value. This gives an increase in bandwidth at the expense of a poorer transient response as shown in Figure 7. In circuits where C1 is not included, the high frequency roll-off point is primarily determined by the characteristics of the output amplifier and not the AD7112.

Feedthrough and accuracy are sensitive to output leakage currents effects. For this reason it is recommended that the operating temperature of the AD7112 be kept as close to 25°C as is practically possible, particularly where the devices performance at high attenuation levels is important. A typical plot of leakage current vs. temperature is shown in Figure 11.

Some solder fluxes and cleaning materials can form slightly conductive films which cause leakage effects between analog input and output. The user is cautioned to ensure that the manufacturing process for circuits using the AD7112 does not allow such films to form. Otherwise the feedthrough, accuracy and maximum usable range will be affected.

STATIC ACCURACY PERFORMANCE

The D/A converter section of the AD7112 consists of a 17-bit R–2R type converter. To obtain optimum static performance at this level of resolution it is necessary to pay great attention to amplifier selection, circuit grounding, etc.

Amplifier input bias current results in a dc offset at the output of the amplifier due to current flowing in the feedback resistor R_{FB}. It is recommended that amplifiers with input bias currents of less than 10 nA be used (e.g., AD712) to minimize this offset.

Another error arises from the output amplifier's input offset voltage. The amplifier is operated with a fixed feedback resistance, but the equivalent source impedance (the AD7112 output impedance) varies as a function of the attenuation level. This has the effect of varying the noise gain of the amplifier thus creating a varying error due to amplifier offset voltage. It is recommended that an amplifier with less than 50 μV of input offset be used (such as the AD712 or ADOP-07) in dc applications. Amplifiers with a large input offset voltage may cause audible thumps in audio applications due to dc output changes. The AD7112 accuracy is specified and tested using only the internal feedback resistor. Any Gain error (i.e., mismatch of R_{FB} to the R–2R ladder) that may exist in the AD7112 D/A converter circuit results in a constant attenuation error over the whole range. The AD7112 accuracy is specified relative to 0 dB attenuation, hence gain trim resistors can be used to adjust $V_{OUT} = V_{IN}$ precisely (i.e., 0 dB attenuation) with input code 00000000. For further information on gain error refer to the "CMOS DAC Application Guide" which is available from Analog Devices, Publication Number G872b–8–1/89.

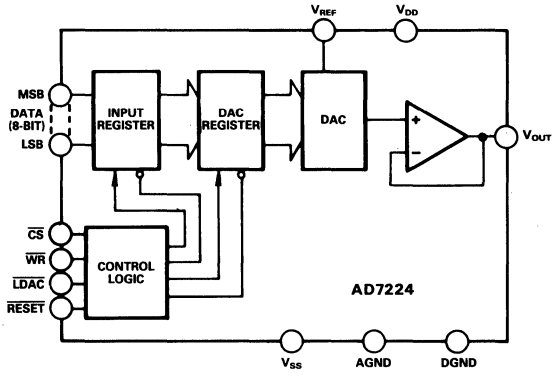
FEATURES

8-Bit CMOS DAC with Output Amplifier
Operates with Single or Dual Supplies
Low Total Unadjusted Error:
Less than 1 LSB Over Temperature
Extended Temperature Range Operation
µP-Compatible with Double Buffered Input
Standard 18-Pin DIPs and 20-Terminal Surface Mount Package and SOIC Package

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7224 is a precision 8-bit, voltage-output, digital-to-analog converter with output amplifier and double buffered interface logic on a monolithic CMOS chip. No external trims are required to achieve full specified performance for the part.

The double buffered interface logic consists of two 8-bit registers–an input register and a DAC register. Only the data held in the DAC register determines the analog output of the converter. The double buffering allows simultaneous update in a system containing multiple AD7224's. Both registers may be made transparent under control of three external lines, $\overline{CS}$, $\overline{WR}$ and $\overline{LDAC}$. With both registers transparent, the $\overline{RESET}$ line functions like a zero override; a useful function for system calibration cycles. All logic inputs are TTL and CMOS (5V) level compatible and the control logic is speed compatible with most 8-bit microprocessors.

Specified performance is guaranteed for input reference voltages from +2V to +12.5V when using dual supplies. The part is also specified for single supply operation using a reference of +10V. The output amplifier is capable of developing +10V across a 2kΩ load.

The AD7224 is fabricated in an all ion-implanted high speed Linear Compatible CMOS (LC²MOS) process which has been specifically developed to allow high speed digital logic circuits and precision analog circuits to be integrated on the same chip.

PRODUCT HIGHLIGHTS

1. DAC and Amplifier on CMOS Chip
   The single-chip design of the 8-bit DAC and output amplifier is inherently more reliable than multi-chip designs. CMOS fabrication means low power consumption (35mW typical with single supply).
2. Low Total Unadjusted Error
   The fabrication of the AD7224 on Analog Devices Linear Compatible CMOS (LC²MOS) process, coupled with a novel DAC switch-pair arrangement, enables an excellent total unadjusted error of less than 1LSB over the full operating temperature range.
3. Single or Dual Supply Operation
   The voltage-mode configuration of the AD7224 allows operation from a single power supply rail. The part can also be operated with dual supplies giving enhanced performance for some parameters.
4. Versatile Interface Logic
   The high speed logic allows direct interfacing to most microprocessors. Additionally, the double buffered interface enables simultaneous update of the AD7224 in multiple DAC systems. The part also features a zero override function.

NOTES
[1]To order MIL-STD-883 processed parts, add /883B to part number. Contact your local sales office for military data sheet.
[2]E = Leadless Ceramic Chip Carrier; N = Plastic DIP; P = Plastic Leaded; Q = Cerdip; R = SOIC. For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

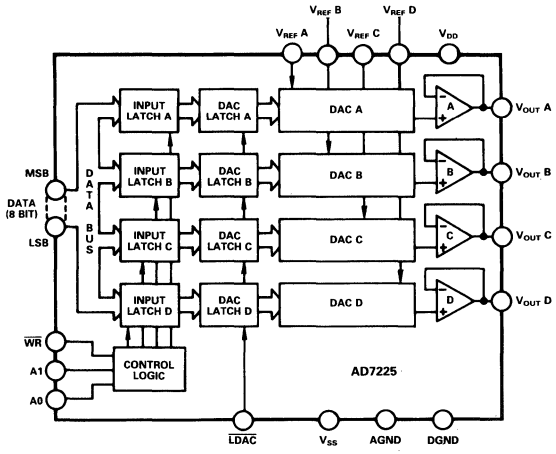
FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7225 contains four 8-bit voltage output digital-to-analog converters, with output buffer amplifiers and interface logic on a single monolithic chip. Each D/A converter has a separate reference input terminal. No external trims are required to achieve full specified performance for the part.

The double-buffered interface logic consists of two 8-bit registers per channel–an input register and a DAC register. Control inputs A0 and A1 determine which input register is loaded when $\overline{WR}$ goes low. Only the data held in the DAC registers determines the analog outputs of the converters. The double-buffering allows simultaneous update of all four outputs under control of $\overline{LDAC}$. All logic inputs are TTL and CMOS (5V) level compatible and the control logic is speed compatible with most 8-bit microprocessors.

Specified performance is guaranteed for input reference voltages from +2V to +12.5V when using dual supplies. The part is also specified for single supply operation using a reference of +10V. Each output buffer amplifier is capable of developing +10V across a 2kΩ load.

The AD7225 is fabricated on an all ion-implanted high-speed Linear Compatible CMOS (LC²MOS) process which has been specifically developed to integrate high-speed digital logic circuits and precision analog circuitry on the same chip.

PRODUCT HIGHLIGHTS

1. DACs and Amplifiers on CMOS Chip
   The single-chip design of four 8-bit DACs and amplifiers allows a dramatic reduction in board space requirements and offers increased reliability in systems using multiple converters. Its pinout is aimed at optimizing board layout with all analog inputs and outputs at one end of the package and all digital inputs at the other.
2. Single or Dual Supply Operation
   The voltage-mode configuration of the AD7225 allows single supply operation. The part can also be operated with dual supplies giving enhanced performance for some parameters.
3. Versatile Interface Logic
   The AD7225 has a common 8-bit data bus with individual DAC latches, providing a versatile control architecture for simple interface to microprocessors. The double-buffered interface allows simultaneous update of the four outputs.
4. Separate Reference Input for Each DAC
   The AD7225 offers great flexibility in dealing with input signals with a separate reference input provided for each DAC and each reference having variable input voltage capability.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[1]Outputs may be shorted to any voltage in the range V_{SS} to V_{DD} provided that the power dissipation of the package is not exceeded. Typical short circuit current for a short to AGND or V_{SS} is 50mA.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

TOTAL UNADJUSTED ERROR

Total Unadjusted Error is a comprehensive specification which includes full scale error, relative accuracy, and zero code error. Maximum output voltage is V_{REF} − 1LSB (ideal), where 1 LSB (ideal) is $V_{REF}/256$. The LSB size will vary over the V_{REF} range. Hence the zero code error will, relative to the LSB size, increase as V_{REF} decreases. Accordingly, the total unadjusted error, which includes the zero code error, will also vary in terms of LSB's over the V_{REF} range. As a result, total unadjusted error is specified for a fixed reference voltage of +10V.

RELATIVE ACCURACY

Relative Accuracy or end-point nonlinearity is a measure of the maximum deviation from a straight line passing through the end-points of the DAC transfer function. It is measured after allowing for zero code error and full scale error and is normally expressed in LSB's or as a percentage of full scale reading.

DIFFERENTIAL NONLINEARITY

Differential Nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range ensures monotonicity.

DIGITAL FEEDTHROUGH

Digital Feedthrough is the glitch impulse transferred to the output of the DAC due to a change in its digital input code. It is specified in nV secs and is measured at V_{REF} = 0V.

DIGITAL CROSSTALK

Digital Crosstalk is the glitch impulse transferred to the output of one converter (not addressed) due to a change in the digital input code to another addressed converter. It is specified in nV secs and is measured at V_{REF} = 0V.

AC FEEDTHROUGH

AC Feedthrough is the proportion of reference input signal which appears at the output of a converter when that DAC is loaded with all 0's.

CHANNEL-TO-CHANNEL ISOLATION

Channel-to-channel isolation is the proportion of input signal from the reference of one DAC (loaded with all 1's) which appears at the output of one of the other three DACs (loaded with all 0's). The figure given is the worst case for the three other outputs and is expressed as a ratio in dBs.

FULL SCALE ERROR

Full Scale Error is defined as:

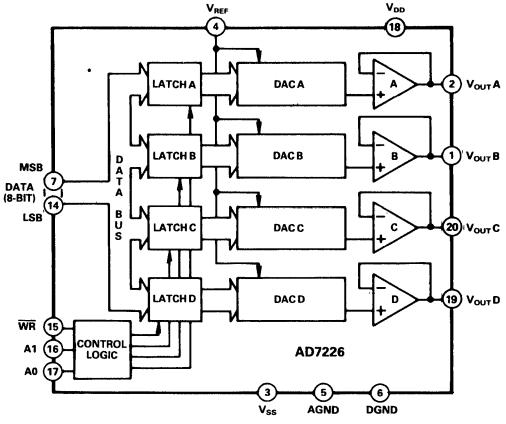
Measured Value – Zero Code Error – Ideal Value

LC²MOS
Quad 8-Bit D/A Converter
AD7226

FEATURES
- Four 8-Bit DACs with Output Amplifiers
- Skinny 20-Pin DIP, SOIC and 20-Terminal Surface Mount Packages
- Microprocessor Compatible
- TTL/CMOS Compatible
- No User Trims
- Extended Temperature Range Operation
- Single Supply Operation Possible

APPLICATIONS
- Process Control
- Automatic Test Equipment
- Automatic Calibration of Large System Parameters, e.g., Gain/Offset

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7226 contains four 8-bit voltage-output digital-to-analog converters, with output buffer amplifiers and interface logic on a single monolithic chip. No external trims are required to achieve full specified performance for the part.

Separate on-chip latches are provided for each of the four D/A converters. Data is transferred into one of these data latches through a common 8-bit TTL/CMOS (5V) compatible input port. Control inputs A0 and A1 determine which DAC is loaded when $\overline{WR}$ goes low. The control logic is speed-compatible with most 8-bit microprocessors.

Each D/A converter includes an output buffer amplifier capable of driving up to 5mA of output current. The amplifiers' offsets are laser-trimmed during manufacture, thereby eliminating any requirement for offset nulling.

Specified performance is guaranteed for input reference voltages from +2V to +12.5V with dual supplies. The part is also specified for single supply operation at a reference of +10V.

The AD7226 is fabricated in an all ion-implanted high speed Linear Compatible CMOS (LC²MOS) process which has been specifically developed to allow high speed digital logic circuits and precision analog circuits to be integrated on the same chip.

PRODUCT HIGHLIGHTS

1. DAC-to-DAC Matching
   Since all four DACs are fabricated on the same chip at the same time, precise matching and tracking between the DACs is inherent.
2. Single Supply Operation
   The voltage mode configuration of the DACs allows the AD7226 to be operated from a single power supply rail.
3. Microprocessor Compatibility
   The AD7226 has a common 8-bit data bus with individual DAC latches, providing a versatile control architecture for simple interface to microprocessors. All latch enable signals are level triggered.
4. Small Size
   Combining four DACs and four op-amps plus interface logic into 20-pin DIP or SOIC or a 20-terminal surface mount package allows a dramatic reduction in board space requirements and offers increased reliability in systems using multiple converters. Its pinout is aimed at optimizing board layout with all the analog inputs and outputs at one end of the package and all the digital inputs at the other.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

TERMINOLOGY

TOTAL UNADJUSTED ERROR
This is a comprehensive specification which includes full-scale error, relative accuracy and zero code error. Maximum output voltage is V_{REF} − 1 LSB (ideal), where 1 LSB (ideal) is $V_{REF}/256$. The LSB size will vary over the V_{REF} range. Hence the zero code error will, relative to the LSB size, increase as V_{REF} decreases. Accordingly, the total unadjusted error, which includes the zero code error, will also vary in terms of LSB's over the V_{REF} range. As a result, total unadjusted error is specified for a fixed reference voltage of +10V.

RELATIVE ACCURACY
Relative Accuracy or end-point nonlinearity, is a measure of the maximum deviation from a straight line passing through the end-points of the DAC transfer function. It is measured after allowing for zero and full-scale error and is normally expressed in LSB's or as a percentage of full-scale reading.

DIFFERENTIAL NONLINEARITY
Differential Nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range ensures monotonicity.

DIGITAL CROSSTALK
The glitch impulse transferred to the output of one converter due to a change in the digital input code to another of the converters. It is specified in nV secs and is measured at V_{REF} = 0V.

FULL-SCALE ERROR
Full-Scale Error is defined as:
Measured Value – Zero Code Error – Ideal Value.

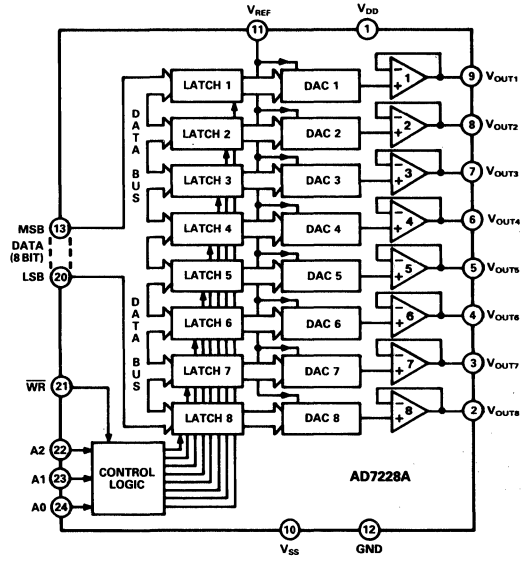
AD7228A

FEATURES

Eight 8-Bit DACs with Output Amplifiers
Operates with Single or Dual Supplies
µP Compatible (95ns $\overline{WR}$ Pulse)
No User Trims Required
Skinny 24-Pin DIPs, SOIC, and 28-Terminal Surface Mount Packages

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7228A contains eight 8-bit voltage-mode digital-to-analog converters, with output buffer amplifiers and interface logic on a single monolithic chip. No external trims are required to achieve full specified performance for the part.

Separate on-chip latches are provided for each of the eight D/A converters. Data is transferred into the data latches through a common 8-bit TTL/CMOS (5V) compatible input port. Address inputs A0, A1 and A2 determine which latch is loaded when $\overline{WR}$ goes low. The control logic is speed compatible with most 8-bit microprocessors.

Specified performance is guaranteed for input reference voltages from +2 to +10V when using dual supplies. The part is also specified for single supply +15V operation using a reference of +10V and single supply +5V operation using a reference of +1.23V. Each output buffer amplifier is capable of developing +10V across a 2kΩ load.

The AD7228A is fabricated on an all ion-implanted, high-speed, Linear Compatible CMOS (LC²MOS) process which has been specifically developed to integrate high-speed digital logic circuits and precision analog circuits on the same chip.

PRODUCT HIGHLIGHTS

1. Eight DACs and Amplifiers in Small Package
   The single-chip design of eight 8-bit DACs and amplifiers allows a dramatic reduction in board space requirements and offers increased reliability in systems using multiple converters. Its pinout is aimed at optimizing board layout with all analog inputs and outputs at one side of the package and all digital inputs at the other.
2. Single or Dual Supply Operation
   The voltage-mode configuration of the DACs allows single supply operation of the AD7228A. The part can also be operated with dual supplies giving enhanced performance for some parameters.
3. Microprocessor Compatibility
   The AD7228A has a common 8-bit data bus with individual DAC latches, providing a versatile control architecture for simple interface to microprocessors. All latch enable signals are level triggered and speed compatible with most high-performance 8-bit microprocessors.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7228A—SPECIFICATIONS

DUAL SUPPLY (V_{DD} = 10.8V to 16.5V; V_{SS} = −5V ±10%; GND = 0V; V_{REF} = +2V to +10V[1]; R_L = 2kΩ, C_L = 100pF unless otherwise stated.) All specifications T_{min} to T_{max} unless otherwise noted.

Specifications subject to change without notice.

SWITCHING CHARACTERISTICS[1, 2] (See Figures 1, 2; V_{DD} = +5V ± 5% or +10.8V to +16.5V; V_{SS} = 0V or −5V ±10%)

Parameters	Limit at 25°C All Grades	Limit at T_{min}, T_{max} (K, L, B, C Grades)	Limit at T_{min}, T_{max} (T, U Grades)	Units	Conditions/Comments
t_1	0	0	0	ns min	Address to $\overline{WR}$ Setup Time
t_2	0	0	0	ns min	Address to $\overline{WR}$ Hold Time
t_3	70	90	100	ns min	Data Valid to $\overline{WR}$ Setup Time
t_4	10	10	10	ns min	Data Valid to $\overline{WR}$ Hold Time
t_5	95	120	150	ns min	Write Pulse Width

NOTES
[1]Sample tested at 25°C to ensure compliance. All input rise and fall times measured from 10% to 90% of +5V, $t_R = t_F = 5$ns.
[2]Timing measurement reference level is $\frac{V_{INH} + V_{INL}}{2}$

INTERFACE LOGIC INFORMATION

Address lines A0, A1 and A2 select which DAC accepts data from the input port. Table I shows the selection table for the eight DACs with Figure 1 showing the input control logic. When the $\overline{WR}$ signal is low, the input latch of the selected DAC is transparent, and its output responds to activity on the data bus. The data is latched into the addressed DAC latch on the rising edge of $\overline{WR}$. While $\overline{WR}$ is high, the analog outputs remain at the value corresponding to the data held in their respective latches.

AD7228A Control Inputs				AD7228A
$\overline{WR}$	A2	A1	A0	Operation
H	X	X	X	No Operation Device Not Selected
L	L	L	L	DAC 1 Transparent
↑	L	L	L	DAC 1 Latched
L	L	L	H	DAC 2 Transparent
L	L	H	L	DAC 3 Transparent
L	L	H	H	DAC 4 Transparent
L	H	L	L	DAC 5 Transparent
L	H	L	H	DAC 6 Transparent
L	H	H	L	DAC 7 Transparent
L	H	H	H	DAC 8 Transparent

H = High State L = Low State X = Don't Care

ABSOLUTE MAXIMUM RATINGS*

V_{DD} to GND	−0.3V, +17V
V_{DD} to V_{SS}	−0.3V, +24V
Digital Input Voltage to GND	−0.3V, V_{DD}
V_{REF} to GND	−0.3V, V_{DD}
V_{OUT} to GND[1]	V_{SS}, V_{DD}
Power Dissipation (Any Package) to +75°C	1000mW
Derates above 75°C by	2.0mW/°C
Operating Temperature	
Commercial	−40°C to +85°C
Industrial	−40°C to +85°C
Extended	−55°C to +125°C
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10secs)	+300°C

NOTE
[1]Outputs may be shorted to any voltage in the range V_{SS} to V_{DD} provided that the power dissipation of the package is not exceeded. Typical short circuit current for a short to GND or V_{SS} is 50mA.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION:

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

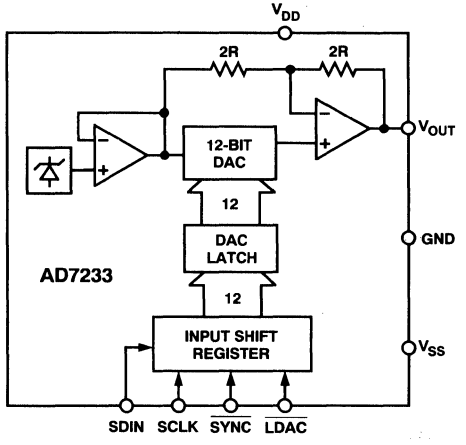
LC²MOS
12-Bit Serial Mini-DIP DACPORT
AD7233

FEATURES
12-Bit CMOS DAC with
On-Chip Voltage Reference
Output Amplifier
−5 V to +5 V Output Range
Serial Interface
300 kHz DAC Update Rate
Small Size : 8-Pin Mini-DIP
Nonlinearity : ±1/2 LSB T_{min} to T_{max}
Low Power Dissipation: 100 mW typical

APPLICATIONS
Process Control
Industrial Automation
Digital Signal Processing Systems
Input/Output Ports

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7233 is a complete 12-bit, voltage-output, digital-to-analog converter with output amplifier and Zener voltage reference all in an 8-pin package. No external trims are required to achieve full specified performance. The data format is 2s complement, and the output range is −5 V to +5 V.

The AD7233 features a fast, versatile serial interface which allows easy connection to both microcomputers and 16-bit digital signal processors with serial ports. When the $\overline{SYNC}$ input is taken low, data on the SDIN pin is clocked into the input shift register on each falling edge of SCLK. On completion of the 16-bit data transfer, bringing $\overline{LDAC}$ low updates the DAC latch with the lower 12 bits of data and updates the output. Alternatively, $\overline{LDAC}$ can be tied permanently low, and in this case the DAC register is automatically updated with the contents of the shift register when all sixteen data bits have been clocked in. The serial data may be applied at rates up to 5 MHz allowing a DAC update rate of 300 kHz.

For applications which require greater flexibility and unipolar output ranges with single supply operation, please refer to the AD7243 data sheet.

The AD7233 is fabricated on Linear Compatible CMOS (LC²MOS), an advanced, mixed-technology process. It is packaged in an 8-pin DIP package.

PRODUCT HIGHLIGHTS

1. Complete 12-Bit DACPORT®
2. The AD7233 is a complete, voltage output, 12-bit DAC on a single chip. This single-chip design is inherently more reliable than multichip designs.
3. Simple 3-Wire Interface to Most Microcontrollers and DSP Processors.
4. DAC Update Rate—300 kHz.
5. Space Saving 8-Pin Package.

DACPORT is a registered trademark of Analog Devices, Inc.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Power Dissipation to +75°C . . . . . 450 mW
Derates above +75°C by . . . . . 10 mW/°C

NOTE
[1]The output may be shorted to voltages in this range provided the power dissipation of the package is not exceeded. Short circuit current is typically 80 mA.
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

TERMINOLOGY

RELATIVE ACCURACY (LINEARITY)

Relative accuracy, or endpoint linearity, is a measure of the maximum deviation of the DAC transfer function from a straight line passing through the endpoints of the transfer function. It is measured after allowing for zero and full-scale errors and is expressed in LSBs or as a percentage of full-scale reading.

DIFFERENTIAL NONLINEARITY

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB or less over the operating temperature range ensures monotonicity.

BIPOLAR ZERO ERROR

Bipolar zero error is the voltage measured at V_{OUT} when the DAC is loaded with all 0s. It is due to a combination of offset errors in the DAC, amplifier and mismatch between the internal gain resistors around the amplifier.

FULL-SCALE ERROR

Full-scale error is a measure of the output error when the amplifier output is at full scale (full scale is either positive or negative full scale).

DIGITAL-TO-ANALOG GLITCH IMPULSE

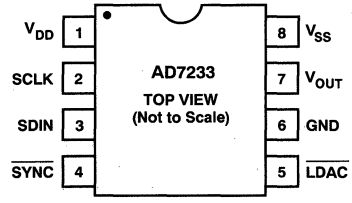
This is the voltage spike that appears at the output of the DAC when the digital code in the DAC latch changes before the output settles to its final value. The energy in the glitch is specified in nV secs, and is measured for an all codes change (0000 0000 0000 to 1111 1111 1111).

DIGITAL FEEDTHROUGH

This is a measure of the voltage spike that appears on V_{OUT} as a result of feedthrough from the digital inputs on the AD7233. It is measured with $\overline{LDAC}$ held high.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	V_{DD}	Positive Supply (+12 V to +15 V).
2	SCLK	Serial Clock, Logic Input. Data is clocked into the input register on each falling SCLK edge.
3	SDIN	Serial Data In, Logic Input. The 16-bit serial data word is applied to this input.
4	$\overline{SYNC}$	Data Synchronization Pulse, Logic Input. Taking this input low initializes the internal logic in readiness for a new data word.
5	$\overline{LDAC}$	Load DAC, Logic Input. Updates the DAC output. The DAC output is updated on the falling edge of this signal, or alternatively if this line in permanently low, an automatic update mode is selected whereby the DAC is updated on the 16th falling SCLK pulse.
6	GND	Ground pin = 0 V.
7	V_{OUT}	Analog Output Voltage. This is the buffered DAC output voltage (−5 V to +5 V).
8	V_{SS}	Negative Supply (−12 V to −15 V).



ORDERING GUIDE

Model	Temperature Range	Relative Accuracy	Package Option*
AD7233AN	−40°C to +85°C	±1 LSB	N-8
AD7233BN	−40°C to +85°C	±1/2 LSB	N-8

*N = Plastic DIP. For outline information see Package Information section.

LC²MOS Dual 12-Bit DACPORTs

AD7237A/AD7247A

FEATURES

Complete Dual 12-Bit DAC Comprising
- **Two 12-Bit CMOS DACs**
- **On-Chip Voltage Reference**
- **Output Amplifiers**
- **Reference Buffer Amplifiers**

Improved AD7237/AD7247:
- **12 V to 15 V Operation**
- **Faster Interface –30 ns typ Data Setup Time**

Parallel Loading Structure: AD7247A
(8+4) Loading Structure: AD7237A
Single or Dual Supply Operation
Low Power – 165 mW typ in Single Supply

GENERAL DESCRIPTION

The AD7237A/AD7247A is an enhanced version of the industry standard AD7237/AD7247. Improvements include operation from 12 V to 15 V supplies, faster interface times and better reference variations with V_{DD}. Additional features include faster settling times.

The AD7237A/AD7247A is a complete, dual, 12-bit, voltage output digital-to-analog converter with output amplifiers and Zener voltage reference on a monolithic CMOS chip. No external user trims are required to achieve full specified performance.

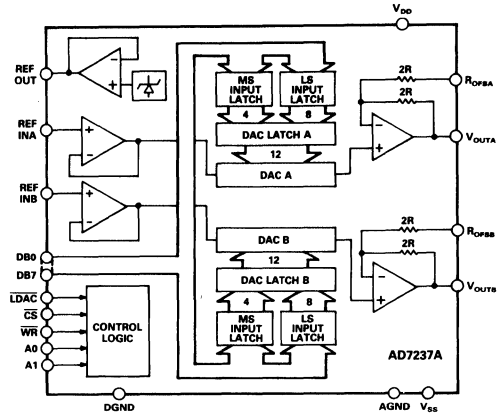
Both parts are microprocessor compatible, with high speed data latches and interface logic. The AD7247A accepts 12-bit parallel data which is loaded into the respective DAC latch using the $\overline{WR}$ input and a separate Chip Select input for each DAC. The AD7237A has a double buffered interface structure and an 8-bit wide data bus with data loaded to the respective input latch in two write operations. An asynchronous $\overline{LDAC}$ signal on the AD7237A updates the DAC latches and analog outputs.

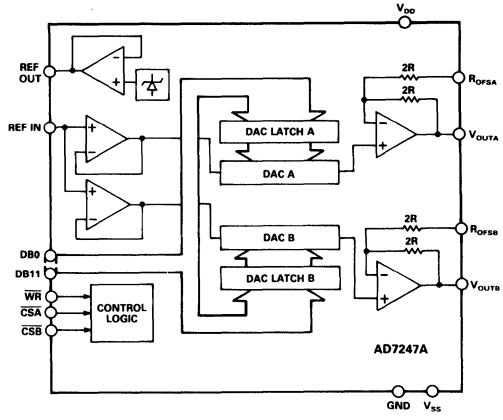
A REF OUT/REF IN function is provided which allows either the on-chip 5 V reference or an external reference to be used as a reference voltage for the part. For single supply operation, two output ranges of 0 to +5 V and 0 to +10 V are available, while these two ranges plus an additional ±5 V range are available with dual supplies. The output amplifiers are capable of developing +10 V across a 2 kΩ load to GND.

The AD7237A/AD7247A is fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. Both parts are available in a 24-pin, 0.3″ wide plastic and hermetic dual-in-line package (DIP) and are also packaged in a 24-lead small outline (SOIC) package.

DACPORT is a registered trademark of Analog Devices, Inc.

FUNCTIONAL BLOCK DIAGRAMS





PRODUCT HIGHLIGHTS

1. The AD7237A/AD7247A is a dual 12-bit DACPORT® on a single chip. This single chip design and small package size offer considerable space saving and increased reliability over multichip designs.
2. The improved interface times of the parts allow easy, direct interfacing to most modern microprocessors, whether they have 8-bit or 16-bit data bus structures.
3. The AD7237A/AD7247A features a wide power supply range allowing operation from 12 V supplies.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7237A/AD7247A—SPECIFICATIONS (V_{DD} = +12 V to +15 V,[1] V_{SS} = 0 V or −12 V to −15 V,[1] AGND = DGND = 0 V [AD7237A], GND = 0 V [AD7247A], REF IN = +5 V, R_L = 2 kΩ, C_L = 100 pF. All specifications T_{min} to T_{max} unless otherwise noted.)

Parameter	A[2]	B[2]	T[2]	Units	Test Conditions/Comments
STATIC PERFORMANCE					
Resolution	12	12	12	Bits	
Relative Accuracy[3]	±1	±1/2	±1/2	LSB max	
Differential Nonlinearity[3]	±0.9	±0.9	±0.9	LSB max	Guaranteed Monotonic
Unipolar Offset Error[3]	±3	±3	±4	LSB max	V_{SS} = 0 V or −12 V to −15 V[4]. DAC Latch Contents All 0s
Bipolar Zero Error[3]	±6	±4	±6	LSB max	V_{SS} = −12 V to −15 V[4]. DAC Latch Contents 1000 0000 0000
Full-Scale Error[3, 5]	±5	±5	±6	LSB max	
Full-Scale Mismatch[5]	±1	±1	±1	LSB typ	
REFERENCE OUTPUT					
REF OUT	4.97/5.03	4.97/5.03	4.95/5.05	V min/max	
Reference Temperature Coefficient	±25	±25	±25	ppm/°C typ	
Reference Load Change (ΔREF OUT vs. ΔI)	−1	−1	−1	mV max	Reference Load Current Change (0–100 μA)
REFERENCE INPUT					
Reference Input Range	4.75/5.25	4.75/5.25	4.75/5.25	V min/max	5 V ± 5%
Input Current[6]	±5	±5	±5	μA max	
DIGITAL INPUTS					
Input High Voltage, V_{INH}	2.4	2.4	2.4	V min	
Input Low Voltage, V_{INL}	0.8	0.8	0.8	V max	
Input Current I_{IN} (Data Inputs)	±10	±10	±10	μA max	V_{IN} = 0 V to V_{DD}
Input Capacitance[6]	8	8	8	pF max	
ANALOG OUTPUTS					
Output Range Resistors	15/30	15/30	15/30	kΩ min/max	
Output Voltage Ranges[7]	+5, +10	+5, +10		V	Single Supply; (V_{SS} = 0 V)
Output Voltage Ranges[7]	+5, +10, ±5	+5, +10, ±5	+5, +10, ±5		Dual Supply; (V_{SS} = −12 V to −15 V[4])
DC Output Impedance	0.5	0.5	0.5	Ω typ	
AC CHARACTERISTICS[6]					
Voltage Output Settling Time					Settling Time to Within ±1/2 LSB of Final Value
Positive Full-Scale Change	8	8	10	μs max	DAC Latch all 0s to all 1s. Typically 5 μs
Negative Full-Scale Change	8	8	10	μs max	DAC Latch all 1s to all 0s. Typically 5 μs V_{SS} = −12 V to −15 V[4].
Digital-to-Analog Glitch Impulse[3]	30	30	30	nV secs typ	DAC Latch Contents Toggled Between all 0's and all 1's.
Digital Feedthrough[3]	10	10	10	nV secs typ	
Digital Crosstalk[3]	30	30	30	nV secs typ	
POWER REQUIREMENTS					
V_{DD}	+10.8/+16.5	+11.4/+15.75	+11.4/+15.75	V min/max	For Specified Performance Unless Otherwise Stated
V_{SS}	−10.8/−16.5	−11.4/−15.75	−11.4/−15.75	V min/max	For Specified Performance Unless Otherwise Stated
I_{DD}	15	15	15	mA max	Output Unloaded. Typically 10 mA
I_{SS} (Dual Supplies)	5	5	5	mA max	Output Unloaded. Typically 3 mA

NOTES
[1]Power Supply tolerance is ±10% for A version and ±5% for B and T versions.
[2]Temperature ranges are as follows: A, B Versions, −40°C to +85°C; T Version, −55°C to +125°C.
[3]See Terminology.
[4]With appropriate power supply tolerances.
[5]Measured with respect to REF IN and includes unipolar/bipolar offset error.
[6]Sample tested @ +25°C to ensure compliance.
[7]0 to +10 V range is only available with $V_{DD} \geq$ 14.25 V.
Specifications subject to change without notice.

TIMING CHARACTERISTICS[1, 2] (V_{DD} = +12 V to +15 V,[3] V_{SS} = 0 V or −12 V to −15 V,[3] AGND = DGND = 0 V [AD7237A], GND = 0 V [AD7247A])

Parameter	Limit at T_{min}, T_{max} (A, B Versions)	Limit at T_{min}, T_{max} (T Version)	Units	Conditions/Comments
t_1	0	0	ns min	$\overline{CS}$ to $\overline{WR}$ Setup Time
t_2	0	0	ns min	$\overline{CS}$ to $\overline{WR}$ Hold Time
t_3	80	100	ns min	$\overline{WR}$ Pulse Width
t_4	80	80	ns min	Data Valid to $\overline{WR}$ Setup Time
t_5[4]	10	10	ns min	Data Valid to $\overline{WR}$ Hold Time
t_6[5]	0	0	ns min	Address to $\overline{WR}$ Setup Time
t_7[5]	0	0	ns min	Address to $\overline{WR}$ Hold Time
t_8[5]	80	100	ns min	$\overline{LDAC}$ Pulse Width

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]See Figures 5 and 7.
[3]Power Supply tolerance is ±10% for A version and ±5% for B and T versions.
[4]If 0 ns<t_2<10 ns, add t_2 to t_5. If $t_2 \geq$ 10 ns, add 10 ns to t_5.
[5]AD7237A only.

ABSOLUTE MAXIMUM RATINGS*

(T_A = +25°C unless otherwise noted)

V_{DD} to GND (AD7247A) . . . . . −0.3 V to +17 V
V_{DD} to AGND, DGND (AD7237A) . . . . . −0.3 V to +17 V
V_{DD} to V_{SS} . . . . . −0.3 V to +34 V
AGND to DGND (AD7237A) . . . . . −0.3 V, V_{DD} +0.3 V
V_{OUTA}[1], V_{OUTB}[1] to AGND (GND)
. . . . . V_{SS} −0.3 V to V_{DD} +0.3 V
REF OUT to AGND (GND) . . . . . 0 V to V_{DD}
REF IN to AGND (GND) . . . . . −0.3 V to V_{DD} +0.3 V
Digital Inputs to DGND (GND) . . . . −0.3 V to V_{DD} +0.3 V
Operating Temperature Range
Industrial (A, B Versions) . . . . . −40°C to +85°C
Extended (T Version) . . . . . −55°C to +125°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 secs) . . . . . +300°C
Power Dissipation (Any Package) to +75°C . . . . . 1000 mW
Derates above +75°C by . . . . . 10 mW/°C

NOTE
[1]Short-circuit current is typically 80mA. The outputs may be shorted to voltages in this range provided the power dissipation of the package is not exceeded.
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ORDERING GUIDE

Model[1]	Temperature Range	Relative Accuracy (LSB)	Package Option[2]
AD7237AAN	−40°C to +85°C	±1 max	N-24
AD7237ABN	−40°C to +85°C	±1/2 max	N-24
AD7237AAR	−40°C to +85°C	±1 max	R-24
AD7237ABR	−40°C to +85°C	±1/2 max	R-24
AD7237ATQ	−55°C to +125°C	±1/2 max	Q-24
AD7247AAN	−40°C to +85°C	±1 max	N-24
AD7247ABN	−40°C to +85°C	±1/2 max	N-24
AD7247AAR	−40°C to +85°C	±1 max	R-24
AD7247ABR	−40°C to +85°C	±1/2 max	R-24
AD7247ATQ	−55°C to +125°C	±1/2 max	Q-24

NOTES
[1]To order MIL-STD-883, Class B processed parts, add /883B to part number. Contact local sales office for military data sheet and availability.
[2]N = Plastic DIP; Q = Cerdip; R = Small Outline (SOIC). For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7237A/AD7247A features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

AD7237A PIN FUNCTION DESCRIPTION (DIP PIN NUMBERS)

Pin	Mnemonic	Description
1	REF INA	Voltage Reference Input for DAC A. The reference voltage for DAC A is applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7237A is 5 V.
2	REF OUT	Voltage Reference Output. The internal 5 V analog reference is provided at this pin. To operate the part with internal reference, REF OUT should be connected to REF INA, REF INB.
3	REF INB	Voltage Reference Input for DAC B. The reference voltage for DAC B is applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7237A is 5 V.
4	R_{OFSB}	Output Offset Resistor for DAC B. This input configures the output ranges for DAC B. It is connected to V_{OUTB} for the +5 V range, to AGND for the +10 V range and to REF INB for the ±5 V range.
5	V_{OUTB}	Analog Output Voltage from DAC B. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and ±5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
6	AGND	Analog Ground. Ground reference for DACs, reference and output buffer amplifiers.
7	DB7	Data Bit 7.
8–10	DB6–DB4	Data Bit 6 to Data Bit 4.
11	DB3	Data Bit 3/Data Bit 11 (MSB).
12	DGND	Digital Ground. Ground reference for digital circuitry.
13	DB2	Data Bit 2/Data Bit 10.
14	DB1	Data Bit 1/Data Bit 9.
15	DB0	Data Bit 0 (LSB)/Data Bit 8.
16	A0	Address Input. Least significant address input for input latches. A0 and A1 select which of the four input latches data is written to (see Table II).
17	A1	Address Input. Most significant address input for input latches.
18	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active.
19	$\overline{WR}$	Write Input. $\overline{WR}$ is an active low logic input which is used in conjunction with $\overline{CS}$, A0 and A1 to write data to the input latches.
20	$\overline{LDAC}$	Load DAC. Logic input. A new word is loaded into the DAC latches from the respective input latches on the falling edge of this signal.
21	V_{DD}	Positive Supply (+12 V to +15 V).
22	V_{OUTA}	Analog Output Voltage from DAC A. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and ±5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
23	V_{SS}	Negative Supply (0 V or −12 V to −15 V).
24	R_{OFSA}	Output Offset Resistor for DAC A. This input configures the output ranges for DAC A. It is connected to V_{OUTA} for the +5 V range, to AGND for the +10 V range and to REF INA for the ±5 V range.

AD7247A PIN FUNCTION DESCRIPTION (DIP PIN NUMBERS)

Pin	Mnemonic	Description
1	REF OUT	Voltage Reference Output. The internal 5 V analog reference is provided at this pin. To operate the part with internal reference, REF OUT should be connected to REF IN.
2	R_{OFSB}	Output Offset Resistor for DAC B. This input configures the output ranges for DAC B. It is connected to V_{OUTB} for the +5 V range, to GND for the +10 V range and to REF IN for the ±5 V range.
