3	V_{OUTB}	Analog Output Voltage from DAC B. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and ±5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
4	DB11	Data Bit 11 (MSB).
5	DB10	Data Bit 10.
6	GND	Ground. Ground reference for all on-chip circuitry.
7–15	DB9–DB1	Data Bit 9 to Data Bit 1.
16	DB0	Data Bit 0 (LSB).
17	$\overline{CSB}$	Chip Select Input for DAC B. Active low logic input. DAC B is selected when this input is active.
18	$\overline{CSA}$	Chip Select Input for DAC A. Active low logic input. DAC A is selected when this input is active.
19	$\overline{WR}$	Write Input. $\overline{WR}$ is an active low logic input which is used in conjunction with $\overline{CSA}$ and $\overline{CSB}$ to write data to the DAC latches.
20	V_{DD}	Positive Supply (+12 V to +15 V).
21	V_{OUTA}	Analog Output Voltage from DAC A. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and ±5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
22	V_{SS}	Negative Supply (0 V or −12 V to −15 V).
23	R_{OFSA}	Output Offset Resistor for DAC A. This input configures the output ranges for DAC A. It is connected to V_{OUTA} for the +5 V range, to GND for the +10 V range and to REF IN for the ±5 V range.
24	REF IN	Voltage Reference Input. The common reference voltage for both DACs is applied to this pin. It is internally buffered before being applied to both DACs. The nominal reference voltage for correct operation of the AD7247A is 5 V.

LC²MOS Dual, Complete, 12-Bit/14-Bit Serial DACs

AD7242/AD7244

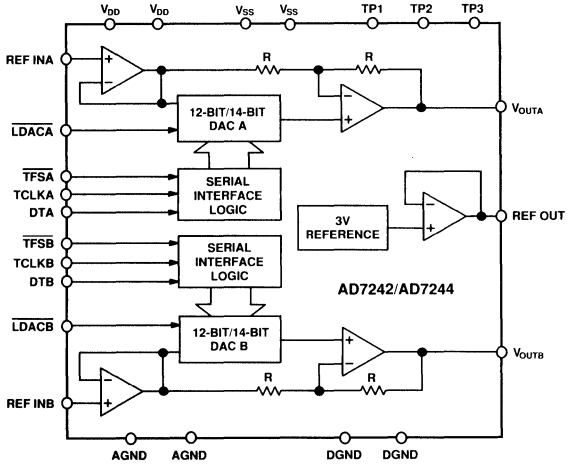
FEATURES

Two 12-Bit/14-Bit DACs with Output Amplifiers
- **AD7242: 12-Bit Resolution**
- **AD7244: 14-Bit Resolution**

On-Chip Voltage Reference
Fast Settling Time
- **AD7242: 3 μs to ±1/2 LSB**
- **AD7244: 4 μs to ±1/2 LSB**

High Speed Serial Interface
Operates from ±5 V Supplies
Specified Over −40°C to +85°C in Plastic Packages
Low Power – 130 mW typ

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7242/AD7244 is a fast, complete, dual 12-bit/14-bit voltage output D/A converter. It consists of a 12-bit/14-bit DAC, 3 V buried Zener reference, DAC output amplifiers and high speed serial interface logic.

Interfacing to both DACs is serial, minimizing pin count and allowing a small package size. Standard control signals allow interfacing to most DSP processors and microcontrollers. Asynchronous control of DAC updating for both DACs is made possible with a separate $\overline{\text{LDAC}}$ input for each DAC.

The AD7242/AD7244 operates from ±5 V power supplies, providing an analog output range of ±3 V. A REF OUT/REF IN function allows the DACs to be driven from the on-chip 3 V reference or from an external reference source.

The AD7242/AD7244 is fabricated in Linear Compatible CMOS (LC²MOS), an advanced mixed technology process that combines precision bipolar circuits with low power CMOS logic. Both parts are available in a 24-pin, 0.3 inch wide, plastic or hermetic dual-in-line package (DIP) and in a 28-pin, plastic small outline (SOIC) package. The AD7242 and AD7244 are available in the same pinout to allow easy upgrade from 12-bit to 14-bit performance.

PRODUCT HIGHLIGHTS

1. Complete, Dual 12-Bit/14-Bit DACs
   The AD7242/AD7244 provides the complete function for generating voltages to 12-bit/14-bit resolution. The part features an on-chip reference, output buffer amplifiers and two 12-bit/14-bit D/A converters.
2. High Speed Serial Interface
   The AD7242/AD7244 provides a high speed, easy-to-use, serial interface allowing direct interfacing to DSP processors and microcontrollers. A separate serial port is provided for each DAC.
3. Small Package Size
   The AD7242/AD7244 is available in a 24-pin DIP and a 28-pin SOIC package offering considerable space saving over comparable solutions.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

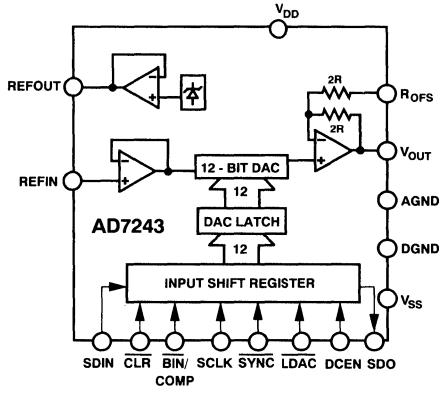
Low Power Dissipation: 100 mW typical

APPLICATIONS

Process Control
Industrial Automation
Digital Signal Processing Systems
Input/Output Ports

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7243 is a complete 12-bit, voltage output, digital-to-analog converter with output amplifier and Zener voltage reference on a monolithic CMOS chip. No external trims are required to achieve full specified performance.

The output amplifier is capable of developing +10 V across a 2 kΩ load. The output voltage ranges with single supply operation are 0 to +5 V or 0 to +10 V, while an additional bipolar ±5 V output range is available with dual supplies. The ranges are selected using the internal gain resistor.

The data format is natural binary in both unipolar ranges, while either offset binary or 2s complement format may be selected in the bipolar range. A $\overline{CLR}$ function is provided which sets the output to 0 V in both unipolar ranges and in the 2s complement bipolar range, while with offset binary data format, the output is set to −REFIN. This function is useful as a power-on reset as it allows the output to be set to a known voltage level.

The AD7243 features a fast versatile serial interface which allows easy connection to both microcomputers and 16-bit digital signal processors with serial ports. The serial data may be applied at rates up to 5 MHz allowing a DAC update rate of 300 kHz. A serial data output capability is also provided which allows daisy chaining in multi-DAC systems. This feature allows any number of DACs to be used in a system with a simple 4-wire interface. All DACs may be updated simultaneously using $\overline{LDAC}$.

The AD7243 is fabricated on Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process. It is packaged in 16-pin DIP and 16-pin SOIC packages.

PRODUCT HIGHLIGHTS

1. Complete 12-Bit DACPORT®
   The AD7243 is a complete, voltage output, 12-bit DAC on a single chip. The single chip design is inherently more reliable than multichip designs.
2. Single or Dual Supply Operation.
3. Minimum 3-wire interface to most DSP processors.
4. DAC Update Rate–300 kHz.
5. Serial Data Output allows easy daisy-chaining in multiple DAC systems.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Operating Temperature Range
Industrial (A, B Versions) . . . . . −40°C to +85°C
Extended (S Version) . . . . . −55°C to +125°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 secs) . . . . . +300°C
Power Dissipation (Any Package) to +75°C . . . . . 450 mW
Derates above +75°C by . . . . . 6 mW/°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any time.
[2]The outputs may be shorted to voltages in this range provided the power dissipation of the package is not exceeded. Short circuit current is typically 80 mA.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN FUNCTION DESCRIPTION (DIP & SOIC PIN NUMBERS)

Pin	Mnemonic	Description
1	REFIN	Voltage Reference Input. It is internally buffered before being applied to the DAC. The nominal reference voltage for specified operation of the AD7243 is 5 V.
2	REFOUT	Voltage Reference Output. The internal 5 V analog reference is provided at this pin. To operate the part using its internal reference, REFOUT should be connected to REFIN.
3	$\overline{CLR}$	Clear, Logic Input. Taking this input low sets V_{OUT} to 0 V in both unipolar ranges and the 2s complement bipolar range and to −REFIN in the offset binary bipolar range.
4	$\overline{BIN}$/COMP	Logic Input . This input selects the data format to be either binary or 2s complement. In both unipolar ranges, natural binary format is selected by connecting this input to a logic "0." In the bipolar configuration, offset binary format is selected with a logic "0" while a logic "1" selects 2s complement format.
5	SCLK	Serial Clock, Logic Input. Data is clocked into the input register on each falling SCLK edge.
6	SDIN	Serial Data In, Logic Input. The 16-bit serial data word is applied to this input.
7	$\overline{SYNC}$	Data Synchronization Pulse, Logic Input. Taking this input low initializes the internal logic in readiness for a new data word.
8	DGND	Digital Ground. Ground reference for all digital circuitry.
9	$\overline{LDAC}$	Load DAC, Logic Input. Updates the DAC output. The DAC output is updated on the falling edge of this signal or alternatively if this line is permanently low, an automatic update mode is selected whereby the DAC is updated on the 16th falling SCLK pulse.
10	DCEN	Daisy-Chain Enable, Logic Input. Connect this pin high if a daisy-chain interface is being used, otherwise this pin must be connected low.
11	SDO	Serial Data Out, Logic Output. With DCEN at Logic "1" this output is enabled, and the serial data in the input shift register is clocked out on each falling SCLK edge.
12	AGND	Analog Ground. Ground reference for all analog circuitry.
13	R_{OFS}	Output Offset Resistor for the amplifier. It is connected to V_{OUT} for the +5 V range, to AGND for the +10 V range and to REFIN for the −5 V to +5 V range.
14	V_{OUT}	Analog Output Voltage. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and −5 V to +5 V.
15	V_{SS}	Negative Power Supply (used for the output amplifier only, may be connected to 0 V for single supply operation or to −12 V to −15 V for dual supplies).
16	V_{DD}	Positive Power Supply (+12 V to +15 V).

ANALOG DEVICES

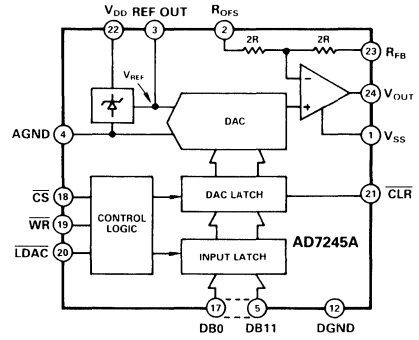
LC²MOS 12-Bit DACPORTs

AD7245A/AD7248A

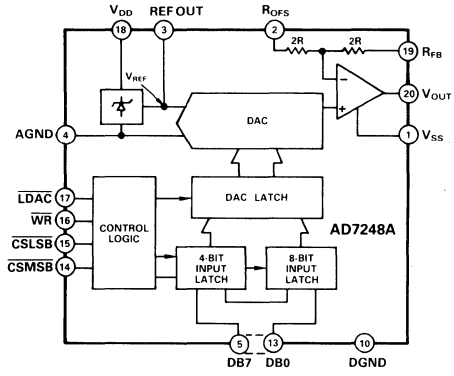
FEATURES

12-Bit CMOS DAC with Output Amplifier and Reference
Improved AD7245/AD7248:
12 V to 15 V Operation
±1/2 LSB Linearity Grade
Faster Interface–30 ns typ Data Setup Time
Extended Plastic Temperature Range (–40°C to +85°C)
Single or Dual Supply Operation
Low Power–65 mW typ in Single Supply
Parallel Loading Structure: AD7245A
(8+4) Loading Structure: AD7248A

AD7245A FUNCTIONAL BLOCK DIAGRAM



AD7248A FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7245A/AD7248A is an enhanced version of the industry standard AD7245/AD7248. Improvements include operation from 12 V to 15 V supplies, a ±1/2 LSB linearity grade, faster interface times and better full scale and reference variations with V_{DD}. Additional features include extended temperature range operation for commercial and industrial grades.

The AD7245A/AD7248A is a complete, 12-bit, voltage output, digital-to-analog converter with output amplifier and Zener voltage reference on a monolithic CMOS chip. No external user trims are required to achieve full specified performance.

Both parts are microprocessor compatible, with high speed data latches and double-buffered interface logic. The AD7245A accepts 12-bit parallel data which is loaded into the input latch on the rising edge of $\overline{CS}$ or $\overline{WR}$. The AD7248A has an 8-bit wide data bus with data loaded to the input latch in two write operations. For both parts, an asynchronous $\overline{LDAC}$ signal transfers data from the input latch to the DAC latch and updates the analog output. The AD7245A also has a $\overline{CLR}$ signal on the DAC latch which allows features such as power-on reset to be implemented.

The on-chip 5 V buried Zener diode provides a low noise, temperature compensated reference for the DAC. For single supply operation, two output ranges of 0 to +5 V and 0 to +10 V are available, while these two ranges plus an additional ±5 V range are available with dual supplies. The output amplifiers are capable of developing +10 V across a 2 kΩ load to GND.

The AD7245A/AD7248A is fabricated in linear compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The AD7245A is available in a small, 0.3″ wide, 24-pin DIP and SOIC and in 28-terminal surface mount packages. The AD7248A is packaged in a small, 0.3″ wide, 20-pin DIP and SOIC and in 20-terminal surface mount packages.

PRODUCT HIGHLIGHTS

1. The AD7245A/AD7248A is a 12-bit DACPORT® on a single chip. This single chip design and small package size offer considerable space saving and increased reliability over multichip designs.
2. The improved interface times on the part allows easy, direct interfacing to most modern microprocessors.
3. The AD7245A/AD7248A features a wide power supply range allowing operation from 12 V supplies.

DACPORT is a registered trademark of Analog Devices, Inc.

NOTES

[1]Power supply tolerance is ±10% for A Version and ±5% for B and T Versions.

[2]Temperature ranges are as follows: A/B Versions; −40°C to +85°C; T Version; −55°C to +125°C.

[3]See Terminology.

[4]With appropriate power supply tolerances.

[5]FSR means Full-Scale Range and is 5 V for the 0 to +5 V output range and 10 V for both the 0 to +10 V and ±5 V output ranges.

[6]This error is calculated with respect to the reference voltage and is measured after the offset error has been allowed for.

[7]This error is calculated with respect to an ideal 4.9988 V on the 0 to +5 V and ±5 V ranges; it is calculated with respect to an ideal 9.9976 V on the 0 to +10 V range. It includes the effects of internal voltage reference, gain and offset errors.

[8]Full-Scale TC = ΔFS/ΔT, where ΔFS is the full-scale change from T_A = +25°C to T_{MIN} or T_{MAX}.

[9]Sample tested at +25°C to ensure compliance.

[10]0 to +10 V output range is available only when $V_{DD} \geq$ +14.25 V.

Specifications subject to change without notice.

NOTE
[1]The output may be shorted to voltages in this range provided the power dissipation of the package is not exceeded. V_{OUT} short circuit current is typically 80 mA.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

TERMINOLOGY

RELATIVE ACCURACY
Relative Accuracy, or end-point nonlinearity, is a measure of the actual deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after allowing for zero and full scale and is normally expressed in LSBs or as a percentage of full-scale reading.

DIFFERENTIAL NONLINEARITY
Differential Nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB max over the operating temperature range ensures monotonicity.

DIGITAL FEEDTHROUGH
Digital Feedthrough is the glitch impulse injected from the digital inputs to the analog output when the inputs change state. It is measured with $\overline{LDAC}$ high and is specified in nV-s.

DAC GAIN ERROR
DAC Gain Error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been allowed for. It is, therefore defined as:

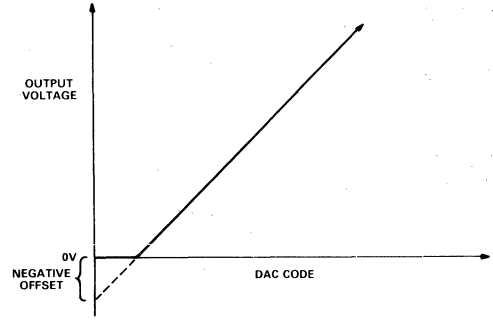
Measured Value—Offset—Ideal Value

where the ideal value is calculated relative to the actual reference value.

UNIPOLAR OFFSET ERROR
Unipolar Offset Error is a combination of the offset errors of the voltage mode DAC and the output amplifier and is measured when the part is configured for unipolar outputs. It is present or all codes and is measured with all 0s in the DAC register.

BIPOLAR ZERO OFFSET ERROR
Bipolar Zero Offset Error is measured when the part is configured for bipolar output and is a combination of errors from the DAC and output amplifier. It is present for all codes and is measured with a code of 2048 (decimal) in the DAC register.

SINGLE SUPPLY LINEARITY AND GAIN ERROR
The output amplifier of the AD7245A/AD7248A can have a true negative offset even when the part is operated from a single positive power supply. However, because the lower supply rail to the part is 0 V, the output voltage cannot actually go negative. Instead the output voltage sits on the lower rail and this results in the transfer function shown across. This is an offset effect and the transfer function would have followed the dotted line if the output voltage could have gone negative. Normally, linearity is measured after offset and full scale have been adjusted or allowed for. On the AD7245A/AD7248A the negative offset is allowed for by calculating the linearity from the code which the amplifier comes off the lower rail. This code is given by the negative offset specification. For example, the single supply linearity specification applies between Code 3 and Code 4095 for the 25°C specification and between Code 5 and Code 4095 over the T_{min} to T_{max} temperature range. Since gain error is also measured after offset has been allowed for, it is calculated between the same codes as the linearity error. Bipolar linearity and gain error are measured between Code 0 and Code 4095.



AD7245A PIN FUNCTION DESCRIPTION
(DIP PIN NUMBERS)

Pin	Mnemonic	Description
1	V_{SS}	Negative Supply Voltage (0 V for single supply operation).
2	R_{OFS}	Bipolar Offset Resistor. This provides access to the on-chip application resistors and allows different output voltage ranges.
3	REF OUT	Reference Output. The on-chip reference is provided at this pin and is used when configuring the part for bipolar outputs.
4	AGND	Analog Ground.
5	DB11	Data Bit 11. Most Significant Bit (MSB).
6–11	DB10–DB5	Data Bit 10 to Data Bit 5.
12	DGND	Digital Ground.
13–16	DB4–DB1	Data Bit 4 to Data Bit 1.
17	DB0	Data Bit 0. Least Significant Bit (LSB).
18	$\overline{CS}$	Chip Select Input (Active LOW). The device is selected when this input is active.
19	$\overline{WR}$	Write Input (Active LOW). This is used in conjunction with $\overline{CS}$ to write data into the input latch of the AD7245A.
20	$\overline{LDAC}$	Load DAC Input (Active LOW). This is an asynchronous input which when active transfers data from the input latch to the DAC latch.
21	$\overline{CLR}$	Clear Input (Active LOW). When this input is active the contents of the DAC latch are reset to all 0s.
22	V_{DD}	Positive Supply Voltage.
23	R_{FB}	Feedback Resistor. This allows access to the amplifier's feedback loop.
24	V_{OUT}	Output Voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V or −5 V to +5 V.

GENERAL DESCRIPTION

The AD7249 contains a pair of 12-bit, voltage-output, digital-to-analog converters with output amplifiers and Zener voltage reference on a monolithic CMOS chip. No external trims are required to achieve full specified performance.

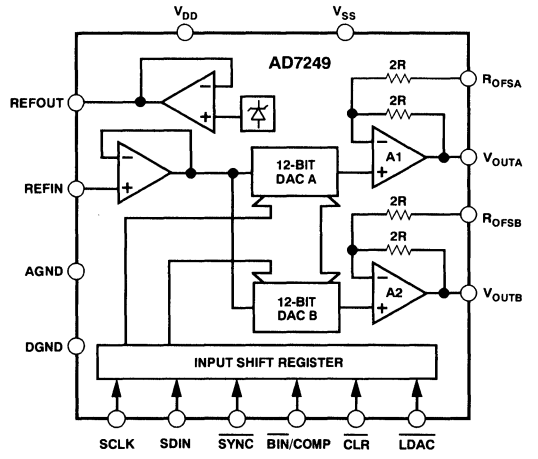
The output amplifiers are capable of developing +10 V across a 2 kΩ load. The output voltage ranges with single supply operation are 0 V to +5 V or 0 V to +10 V, while an additional bipolar ±5 V output range is available with dual supplies. The ranges are selected using the internal gain resistor.

Interfacing to the AD7249 is serial, minimizing pin count and allowing a small package size. Standard control signals allow interfacing to most DSP processors and microcontrollers. The data stream consists of 16 bits, DB15 to DB13 are don't care bits, the 13th bit (DB12) is used as the channel select bit and the remaining 12 bits (DB11 to DB0) contain the data to update the DAC. The 16-bit data word is clocked into the input register on each falling SCLK edge.

The data format is natural binary in both unipolar ranges, while either offset binary or twos complement format may be selected in the bipolar range. A $\overline{CLR}$ function is provided which sets the output to 0 V in both unipolar ranges and in the twos complement bipolar range, while with offset binary data format, the output is set to −REFIN. This function is useful as a power-on reset as it allows the outputs to be set to a known voltage level.

DACPORT is a registered trademark of Analog Devices, Inc.

FUNCTIONAL BLOCK DIAGRAM



The AD7249 features a serial interface which allows easy connection to both microcomputers and 16-bit digital signal processors with serial ports. The serial data may be applied at rates up to 2 MHz allowing a DAC update rate of 125 kHz.

The AD7249 is fabricated on linear compatible CMOS (LC²MOS), an advanced, mixed technology process. It is packaged in 16-pin DIP and 16-pin SOIC packages.

PRODUCT HIGHLIGHTS

1. Two complete 12-bit DACPORTs®
   The AD7249 contains two complete voltage output, 12-bit DACs in both 16-lead DIP and SOIC packages.
2. Single or dual supply operation
3. Minimum 3-wire interface to most DSP processors
4. DAC update rate—125 kHz

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any time.
[2]The outputs may be shorted to voltages in this range provided the power dissipation of the package is not exceeded.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7249 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN FUNCTION DESCRIPTION (DIP & SOIC PIN NUMBERS)

Pin	Mnemonic	Description
1	REFOUT	Voltage Reference Output. The internal 5 V analog reference is provided at this pin. To operate the part using its internal reference, REFOUT should be connected to REFIN.
2	REFIN	Voltage Reference Input. It is internally buffered before being applied to both DACs. The nominal reference voltage for specified operation of the AD7249 is 5 V.
3	R_{OFSB}	Output Offset Resistor for the amplifier of DAC B. It is connected to V_{OUTB} for the +5 V range, to AGND for the +10 V range and to REFIN for the −5 V to +5 V range.
4	V_{OUTB}	Analog Output Voltage of DAC B. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and −5 V to +5 V.
5	AGND	Analog Ground. Ground reference for all analog circuitry.
6	$\overline{CLR}$	Clear, Logic Input. Taking this input low clears both DACs. It sets V_{OUTA} and V_{OUTB} to 0 V in both unipolar ranges and the twos complement bipolar range and to −REFIN in the offset binary bipolar range.
7	$\overline{BIN}$/COMP	Logic Input. This input selects the data format to be either binary or twos complement. In both unipolar ranges natural binary format is selected by connecting this input to a Logic "0". In the bipolar configuration offset binary format is selected with a logic "0" while a Logic "1" selects twos complement.
8	DGND	Digital Ground. Ground reference for all digital circuitry.
9	SDIN	Serial Data In, Logic Input. The 16-bit serial data word is applied to this input.
10	$\overline{LDAC}$	Load DAC, Logic Input. Updates both DAC outputs. The DAC outputs are updated on the falling edge of this signal or alternatively if this line is permanently low, an automatic update mode is selected whereby both DACs are updated on the 16th falling SCLK pulse.
11	SCLK	Serial Clock, Logic Input. Data is clocked into the input register on each falling SCLK edge.
12	$\overline{SYNC}$	Data Synchronization Pulse, Logic Input. Taking this input low initializes the internal logic in readiness for a new data word.
13	V_{DD}	Positive Power Supply.
14	V_{OUTA}	Analog Output Voltage of DAC A. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and −5 V to +5 V.
15	V_{SS}	Negative Power Supply (used for the output amplifier only) may be connected to 0 V for single supply operation or −12 V to −15 V for dual supplies.
16	R_{OFSA}	Output Offset Resistor for the amplifier of DAC A. It is connected to V_{OUTA} for the +5 V range, to AGND for the +10 V range and to REFIN for the −5 V to +5 V range.

TERMINOLOGY

Bipolar Zero Error
Bipolar Zero Error is the voltage measured at V_{OUT} when the DAC is configured for bipolar output and loaded with all 0s (Twos Complement Coding) or with 1000 0000 0000 (Offset Binary Coding). It is due to a combination of offset errors in the DAC, amplifier and mismatch between the internal gain resistors around the amplifier.

Full-Scale Error
Full-Scale Error is a measure of the output error when the amplifier output is at full scale (for the bipolar output range full scale is either positive or negative full scale). It is measured with respect to the reference input voltage and includes the offset errors.

Digital-to-Analog Glitch Impulse
This is the voltage spike that appears at V_{OUT} when the digital code in the DAC Latch changes, before the output settles to its final value. The energy in the glitch is specified in nV secs, and is measured for an all codes change from 0000 0000 0000 to 1111 1111 1111.

Digital Feedthrough
This is a measure of the voltage spike that appears on V_{OUT} as a result of feedthrough from the digital inputs on the AD7249. It is measured with $\overline{LDAC}$ held high.

Relative Accuracy (Linearity)
Relative Accuracy, or endpoint linearity, is a measure of the maximum deviation of the DAC transfer function from a straight line passing through the endpoints of the transfer function. It is measured after allowing for zero and full-scale errors and is expressed in LSBs or as a percentage of full-scale reading.

Single Supply Linearity and Gain Error
The output amplifier on the AD7249 can have true negative offsets even when the part is operated from a single +15 V supply. However, because the negative supply rail (V_{SS}) is 0 V, the output cannot actually go negative. Instead, when the output offset voltage is negative, the output voltage sits at 0 V, resulting in the transfer function shown in Figure 1.

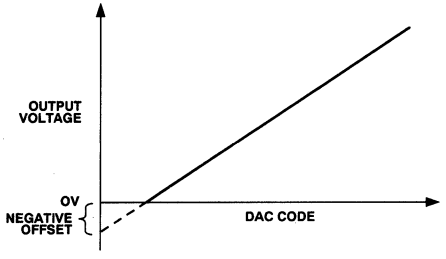

Figure 1. Effect of Negative Offset (Single Supply)

This "knee" is an offset effect, not a linearity error, and the transfer function would have followed the dotted line if the output voltage could have gone negative.

Normally, linearity is measured between zero (all 0s input code) and full scale (all 1s input code) after offset and full scale have been adjusted out or allowed for, but this is not possible in single supply operation if the offset is negative, due to the knee in the transfer function. Instead, linearity of the AD7249 in the unipolar mode is measured between full scale and the lowest code which is guaranteed to produce a positive output voltage. This code is calculated from the maximum specification for negative offset. For the A and B versions, the linearity is measured between Codes 3 and 4095. For the S grade, linearity is measured between Code 5 and Code 4095.

Differential Nonlinearity
Differential Nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB or less over the operating temperature range ensures monotonicity.

Unipolar Offset Error
Unipolar Offset Error is the measured output voltage from V_{OUT} with all zeros loaded into the DAC latch, when the DAC is configured for unipolar output. It is due to a combination of the offset errors in the DAC and output amplifier.

CIRCUIT INFORMATION

D/A Section
The AD7249 contains two 12-bit voltage-mode D/A converters consisting of highly stable thin film resistors and high-speed NMOS single-pole, double-throw switches. The simplified circuit diagram for the DAC section is shown in Figure 2. The output voltage from the converter has the same polarity as the reference voltage, REFIN, allowing single supply operation.

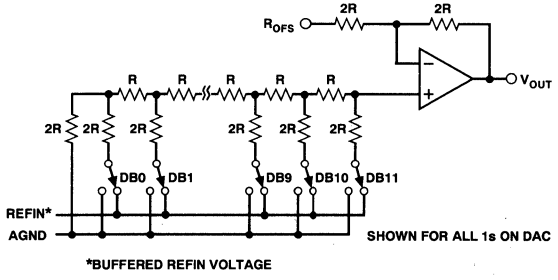

Figure 2. D/A Simplified Circuit Diagram

Internal Reference

The AD7249 has an on-chip temperature compensated buried Zener reference which is factory trimmed to 5 V ± 50 mV. The reference voltage is provided at the REFOUT pin. This reference can be used to provide the reference voltage for the D/A converter by connecting the REFOUT pin to the REFIN pin.

The reference voltage can also be used as a reference for other components and is capable of providing up to 500 μA to an external load. The maximum recommended capacitance on REFOUT for normal operation is 50 pF. If the reference output is required to drive a capacitive load greater than 50 pF, then a 200 Ω resistor should be placed in series with the capacitive load. Figure 3 shows the suggested REF OUT decoupling scheme, a 200 Ω resistor and the parallel combination of a 10 μF tantalum and a 0.1 μF ceramic capacitor. This decoupling scheme reduces the noise spectral density of the reference.

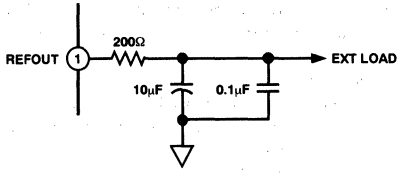

Figure 3. Reference Decoupling Scheme

External Reference

In some applications, the user may require a system reference or some other external reference to drive the AD7249. References such as the AD586 provide an ideal external reference source (See Figure 10). The REFIN voltage is internally buffered by a unity gain amplifier before being applied to the D/A converter. The D/A converter is scaled for a 5 V reference and the device is tested with 5 V applied to REFIN. Other reference voltages may be used with degraded performance. Figure 4 shows the degradation in linearity vs. REFIN.

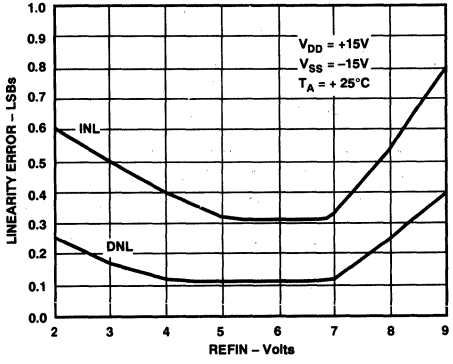

Figure 4. Linearity vs. REFIN Voltage

Op Amp Section

The output of the voltage-mode D/A converter is buffered by a noninverting CMOS amplifier. The R_{OFS} input allows three output voltage ranges to be selected. The buffer amplifier is capable of developing +10 V across a 2 kΩ load to AGND.

The output amplifier can be operated from a single +15 V supply by tying V_{SS} = 0 V.

The amplifier can also be operated from dual supplies to allow an additional bipolar output range of −5 V to +5 V. Dual supplies are necessary for the bipolar output range but can also be used for the unipolar ranges to give faster settling time to voltages near 0 V, to allow full sink capability of 2.5 mA over the entire output range and to eliminate the effects of negative offsets on the transfer characteristic (outlined previously). A plot of the output sink capability of the amplifier is shown in Figure 5.

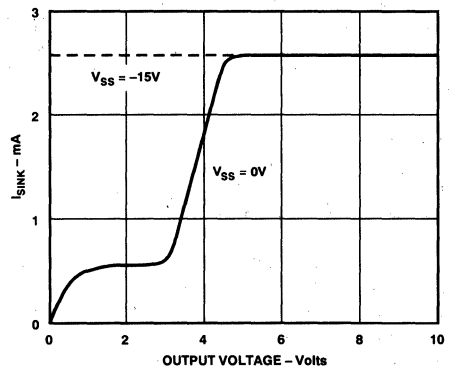

Figure 5. Amplifier Sink Current

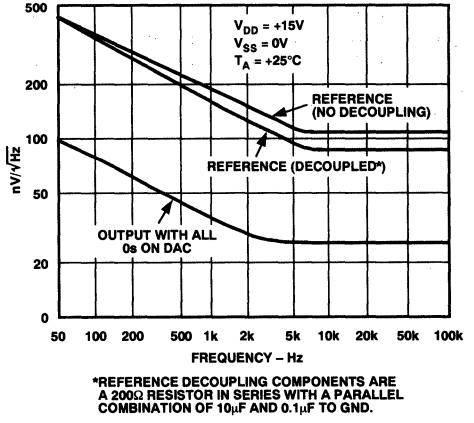

Figure 6. Noise Spectral Density vs. Frequency

DIGITAL INTERFACE

The AD7249 contains an input serial to parallel shift register and a DAC latch for both DAC A and DAC B. A simplified diagram of the input loading circuitry is shown in Figure 7. Serial data on the SDIN input is loaded to the input register under control of $\overline{SYNC}$ and SCLK. The $\overline{SYNC}$ input provides the frame synchronization signal which tells the AD7249 that valid serial data on the SDIN input will be available for the next 16 falling edges of SCLK. An internal counter/decoder circuit provides a low gating signal so that only 16 data bits are clocked into the input shift register. After 16 SCLK pulses the internal gating signal goes inactive (high) thus locking out any further clock pulses. Therefore either a continuous clock or a burst clock source may be used to clock in the data. The $\overline{SYNC}$ input is taken high after the complete 16-bit word is loaded in.

DAC selection is accomplished using the thirteenth bit (DB12) of the serial data input stream. A zero in DB12 will select DAC A while a one in this position selects DAC B. Although 16 bits of data are clocked into the input register, only 12 bits get transferred into the DAC latch. The relevant DAC latch is determined by the value of the thirteenth bit and the first three bits in the 16-bit stream are don't cares. Therefore, the data format is three don't cares followed by the DAC selection bit and the 12-bit data word with the LSB as the last bit in the serial stream.

There are two ways in which a DAC latches and hence the analog outputs may be updated. The status of the $\overline{LDAC}$ input is examined after $\overline{SYNC}$ is taken low. Depending on its status, one of two update modes are selected.

If $\overline{LDAC}$ = 0, then the automatic update mode is selected. In this mode the DAC latch and analog output are updated automatically when the last bit in the serial data stream is clocked in. The update thus takes place on the sixteenth falling SCLK edge.

If $\overline{LDAC}$ = 1, then the automatic update is disabled and both DAC latches are updated by taking $\overline{LDAC}$ low any time after the 16-bit data transfer is complete. The update now occurs on the falling edge of $\overline{LDAC}$. Note that the $\overline{LDAC}$ input must be taken back high again before the next data transfer is initiated. When a complete word is held in the shift register it may then be loaded into the DAC latch under control of $\overline{LDAC}$.

Clear Function ($\overline{CLR}$)

The clear function clears the contents of the input shift register and loads both DAC Latches with all 0s. It is activated by taking $\overline{CLR}$ low. In all ranges except the Offset Binary bipolar range (−5 V to +5 V) the output voltage is reset to 0 V. In the offset binary bipolar range the output is set to −REFIN. The clear function is especially useful at power-up as it enables the output to be reset to a known state.

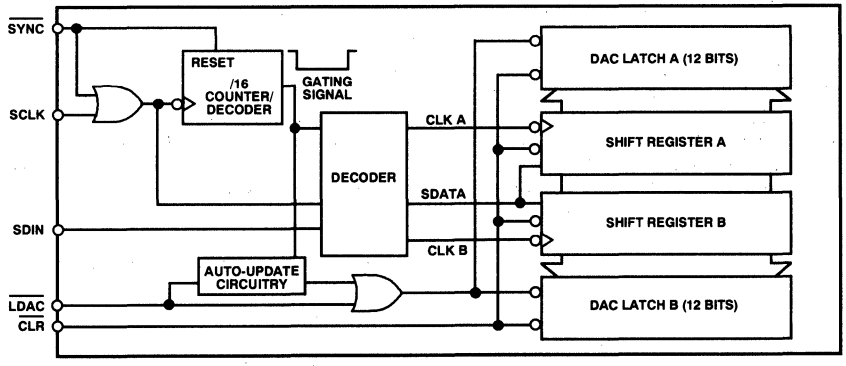

Figure 7. Simplified Loading Structure

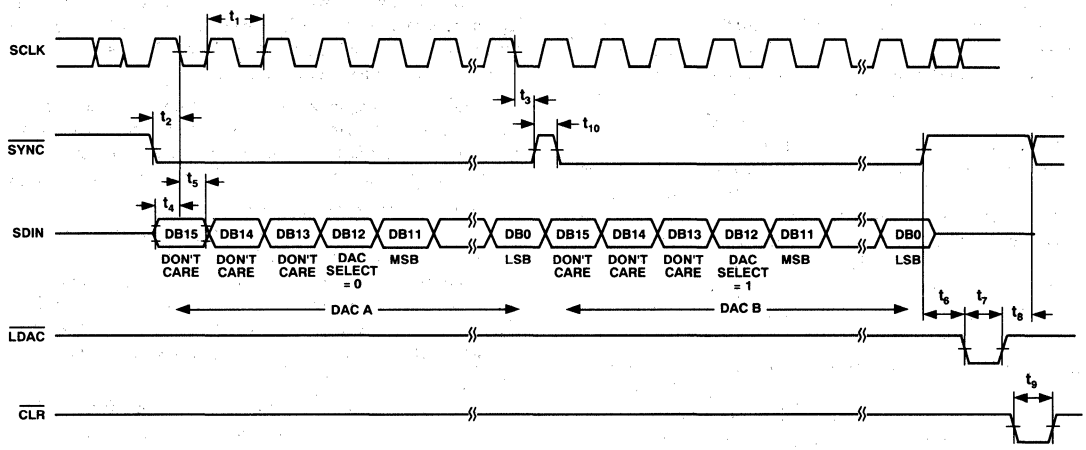

Figure 8. Timing Diagram

TRANSFER FUNCTION

The internal scaling resistors provided on the AD7249 allow several output voltage ranges. The part can produce unipolar output ranges of 0 V to +5 V or 0 V to +10 V and a bipolar output range of ±5 V. Connections for the various ranges are outlined below. Since each DAC has its own R_{OFS} input the two DACs can be set up for different output ranges.

Unipolar (0 V to +10 V) Configuration

The first of the configurations provides an output voltage range of 0 V to +10 V. This is achieved by connecting the output offset resistor R_{OFSA}, R_{OFSB} (Pin 3, 16) to AGND. Natural Binary data format is selected by connecting $\overline{BIN}$ / COMP (Pin 7) to DGND. In this configuration, the AD7249 can be operated using either single or dual supplies. Note that the V_{DD} supply is restricted to +15 V ± 10% for this range in order to maintain sufficient amplifier headroom. Dual supplies may be used to improve settling time and give increased current sink capability for the amplifier. Figure 9 shows the connection diagram for unipolar operation of the AD7249. Table I shows the digital code vs. analog output for this configuration.

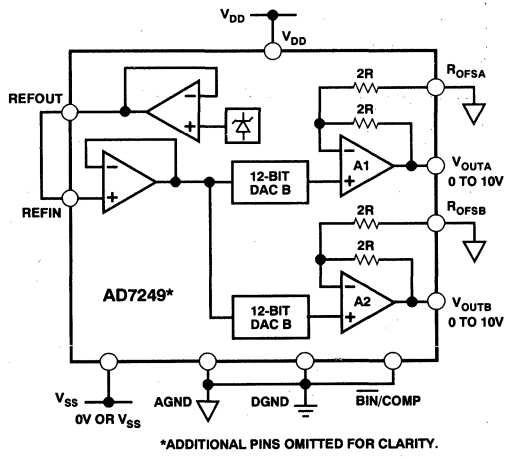

Figure 9. Unipolar (0 V to +10 V) Configuration

Unipolar (0 V to +5 V) Configuration

The 0 V to +5 V output voltage range is achieved by tying R_{OFSA} to V_{OUTA} or R_{OFSB} to V_{OUTB}. Once again, the AD7249 can be operated using either single or dual supplies. The table for output voltage versus digital code is as in Table I, with 2REFIN replaced by REFIN. Note, for this range, 1 LSB = REFIN · (2^{-12}) = (REFIN/4096).

Table I. Unipolar Code Table (0 V to +10 V Range)

Input Data Word MSB LSB	Analog Output, V_{OUT}
XXXY 1111 1111 1111	+2REFIN · (4095/4096)
XXXY 1000 0000 0001	+2REFIN · (2049/4096)
XXXY 1000 0000 0000	+2REFIN · (2048/4096) = +REFIN
XXXY 0111 1111 1111	+2REFIN · (2047/4096)
XXXY 0000 0000 0001	+2REFIN · (1/4096)
XXXY 0000 0000 0000	0 V

X = Don't Care.
Y = DAC Select Bit, 0 = DACA, 1= DACB.
Note: 1 LSB = 2REFIN/4096.

Bipolar (±5 V) Configuration

The bipolar configuration for the AD7249, which gives an output range of −5 V to +5 V, is achieved by connecting R_{OFSA}, R_{OFSB} to V_{REFIN}. The AD7249 must be operated from dual supplies to achieve this output voltage range. Either offset binary or twos complement coding may be selected. Figure 10 shows the connection diagram for bipolar operation. An AD586 provides the reference voltage for the DAC but this could be provided by the on-chip reference by connecting REFOUT to REFIN.

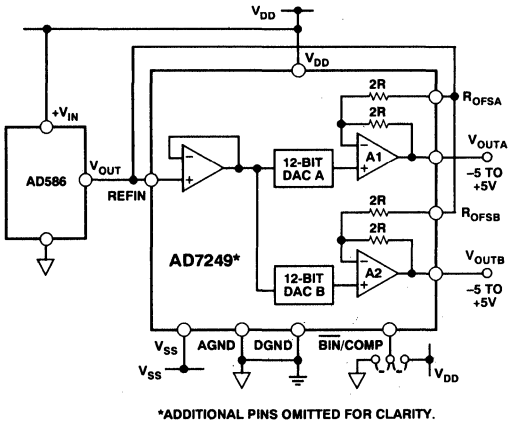

Figure 10. Bipolar Configuration with External Reference

Bipolar Operation (Twos Complement Data Format)

The AD7249 is configured for twos complement data format by connecting $\overline{\text{BIN}}$/COMP (Pin 7) high. The analog output vs. digital code is shown in Table II.

Table II. Twos Complement Bipolar Code Table

Input Data Word MSB LSB	Analog Output, V_{OUT}
XXXY 0111 1111 1111	+REFIN · (2047/2048)
XXXY 0000 0000 0001	+REFIN · (1/2048)
XXXY 0000 0000 0000	0 V
XXXY 1111 1111 1111	−REFIN · (1/2048)
XXXY 1000 0000 0001	−REFIN · (2047/2048)
XXXY 1000 0000 0000	−REFIN · (2048/2048)=−REFIN

X = Don't Care.
Y = DAC Select Bit, 0 = DACA, 1 = DACB.
Note: 1 LSB = REFIN/2048.

Bipolar Operation (Offset Binary Data Format)

The AD7249 is configured for Offset Binary data format by connecting $\overline{\text{BIN}}$/COMP (Pin 7) low. The analog output vs. digital code may be obtained by inverting the MSB in Table II.

APPLYING THE AD7249

Good printed circuit board layout is as important as the overall circuit design itself in achieving high speed converter performance. The AD7249 works on an LSB size of 2.44 mV for the unipolar 0 V to 10 V range and the bipolar ±5 V range, when using the unipolar 0 V to 5 V range the LSB size is 1.22 mV. Therefore the designer must be conscious of minimizing noise in both the converter itself and in the surrounding circuitry. Switching mode power supplies are not recommended as switching spikes can feedthrough to the on-chip amplifier. Other causes of concern are ground loops and feedthrough from microprocessors. These are factors which influence any high performance converter, and proper printed circuit board layout which minimizes these effects is essential to obtain high performance.

LAYOUT HINTS

Ensure that the layout has the digital and analog tracks separated as much as possible. Take care not to run any digital track alongside an analog signal track. Establish a single point analog ground separate from the logic system ground. Place this star ground as close as possible to the AD7249. Connect all analog grounds to this star point and also connect the AD7249 DGND pin to this point. Do not connect any other digital grounds to this analog ground point. Low impedance analog and digital power supply common returns are essential for low noise operation of high performance converters. To accomplish this track widths should be kept a wide as possible and also the use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise.

NOISE

Keep the signal leads on the V_{OUTA} and V_{OUTB} signals and the signal return leads to AGND as short as possible to minimize noise coupling. In applications where this is not possible use a shielded cable between the DAC outputs and their destination. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the DAC and its destination device appears as an error voltage in series with the DAC output.

Power Supply Decoupling

To achieve optimum performance when using the AD7249, the V_{DD} and V_{SS} lines should be decoupled to AGND using 0.1 μF capacitors. In noisy environments it is recommended that 10 μF capacitors be connected in parallel with the 0.1 μF capacitors.

MICROPROCESSOR INTERFACING

Microprocessor interfacing to the AD7249 is via a serial bus which uses standard protocol compatible with DSP processors and microcontrollers. The communications channel requires a three-wire interface consisting of a clock signal, a data signal and a synchronization signal. The AD7249 requires a 16-bit data word with data valid on the falling edge of SCLK. For all the interfaces, the DAC update may be done automatically when all the data is clocked in or it may be done under control of $\overline{\text{LDAC}}$.

Figures 11 to 15 show the AD7249 configured for interfacing to a number of popular DSP processors and microcontrollers.

AD7249–ADSP-2101/ADSP-2102 Interface

Figure 11 shows a serial interface between the AD7249 and the ADSP-2101/ ADSP-2102 DSP processor. The ADSP-2101/ ADSP-2102 contains two serial ports and either port may be used in the interface. The data transfer is initiated by $\overline{\text{TFS}}$ going low. Data from the ADSP-2101/ADSP-2102 is clocked into the AD7249 on the falling edge of SCLK. DB12 of the 16-bit serial data stream selects the DAC to be updated. Both DACs can be updated by holding $\overline{\text{LDAC}}$ high while performing two write cycles to the DAC. $\overline{\text{TFS}}$ must be taken high after each 16 bit write cycle. $\overline{\text{LDAC}}$ is brought low at the end of the second cycle and both DAC outputs are updated together. In the interface shown the DAC is updated using an external timer

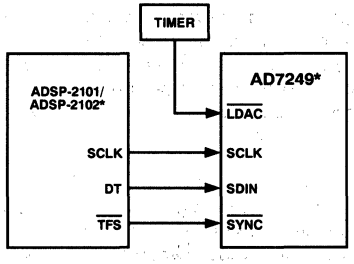

Figure 11. AD7249–ADSP-2101/ADSP-2102 Interface

which generates an $\overline{\text{LDAC}}$ pulse. This could also be done using a control or decoded address line from the processor. Alternatively, if the $\overline{\text{LDAC}}$ input is hardwired low the output update takes place automatically on the 16th falling edge of SCLK.

AD7249–DSP56000 Interface

A serial interface between the AD7249 and the DSP56000 is shown in Figure 12. The DSP56000 is configured for Normal Mode Asynchronous operation with Gated Clock. It is also set up for a 16-bit word with SCK and SC2 as outputs and the FSL control bit set to a "0." SCK is internally generated on the DSP56000 and applied to the AD7249 SCLK input. Data from the DSP56000 is valid on the falling edge of SCK. The SC2 output provides the framing pulse for valid data. This line must be inverted before being applied to the $\overline{\text{SYNC}}$ input of the AD7249.

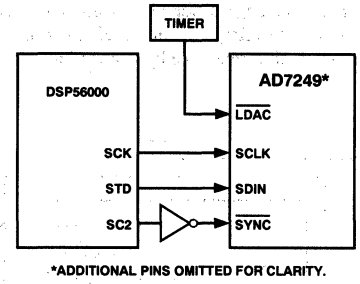

Figure 12. AD7249–DSP5600 Interface

In this interface an external $\overline{\text{LDAC}}$ pulse generated from an external timer is used to update the outputs of the DACs. This update can also be produced using a bit programmable control line from the DSP56000.

AD7249–TMS32020 Interface

Figure 13 shows a serial interface between the AD7249 and the TMS32020 DSP processor. In this interface, the CLKX and FSX signals for the TMS32020 should be generated using external clock/timer circuitry. The FSX pin of the TMS32020 must be configured as an input. Data from the TMS32020 is valid on the falling edge of CLKX.

The clock/timer circuitry generates the $\overline{\text{LDAC}}$ signal for the AD7249 to synchronize the update of the output with the serial transmission. Alternatively, the automatic update mode may be selected by connecting $\overline{\text{LDAC}}$ to DGND.

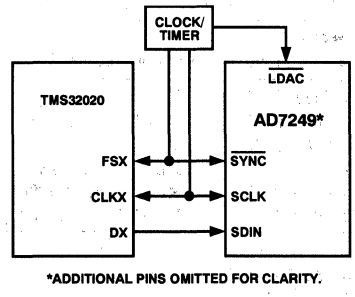

Figure 13. AD7249–TMS32020 Interface

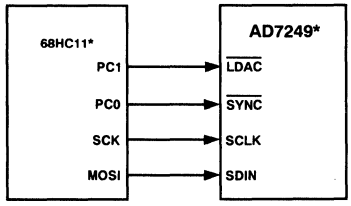
AD7249–68HC11 Interface

Figure 14 shows a serial interface between the AD7249 and the 68HC11 microcontroller. SCK of the 68HC11 drives SCLK of the AD7249 while the MOSI output drives the serial data line of the AD7249. The $\overline{SYNC}$ signal is derived from a port line (PC0 shown).

For correct operation of this interface, the 68HC11 should be configured such that its CPOL bit is a 0 and its CPHA bit is a 1. When data is to be transmitted to the part, PC0 is taken low. When the 68HC11 is configured like this, data on MOSI is valid on the falling edge of SCK. The 68HC11 transmits its serial data in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. To load data to the AD7249, PC0 is left low after the first eight bits are transferred and a second byte of data is then transferred serially to the AD7249. When the second serial transfer is complete, the PC0 line is taken high.

Figure 14 shows the $\overline{LDAC}$ input of the AD7249 being driven from another bit programmable port line (PC1). As a result, both DACs can be updated simultaneously by taking $\overline{LDAC}$ low after both DACs latches have updated.



*ADDITIONAL PINS OMITTED FOR CLARITY.

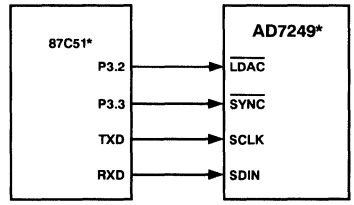
Figure 14. AD7249–68HC11 Interface

AD7249–87C51 Interface

A serial interface between the AD7249 and the 87C51 microcontroller is shown in Figure 15. TXD of the 87C51 drives SCLK of the AD7249 while RXD drives the serial data line of the part. The $\overline{SYNC}$ signal is derived from the port line P3.3 and the $\overline{LDAC}$ line is driven port line P3.2.

The 87C51 provides the LSB of its SBUF register as the first bit in the serial data stream. Therefore, the user will have to ensure that the data in the SBUF register is arranged correctly so that the don't care bits are the first to be transmitted to the AD7249 and the last bit to be sent is the LSB of the word to be loaded to the AD7249. When data is to be transmitted to the part, P3.3 is taken low. Data on RXD is valid on the falling edge of TXD. The 87C51 transmits its serial data in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. To load data to the AD7249, P3.3 is left low after the first eight bits are transferred, and a second byte of data is then transferred serially to the AD7249 with DB12 used to select the appropriate DAC register. When the second serial transfer is complete, the P3.3 line is taken high and then taken low again to start the loading sequence to the second DAC (see timing diagram Figure 8).

Figure 15 shows the $\overline{LDAC}$ input of the AD7249 driven from the bit programmable port line P3.2. As a result, both DAC outputs can be updated simultaneously by taking the $\overline{LDAC}$ line low following the completion of the write cycle to the second DAC. Alternatively $\overline{LDAC}$ could be hardwired low and the analog output will be updated on the sixteenth falling edge of TXD after the $\overline{SYNC}$ signal for the DAC has gone low.



*ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 15. AD7249–87C51 Interface

APPLICATIONS

OPTO-ISOLATED INTERFACE

In many process control type applications it is necessary to provide an isolation barrier between the controller and the unit being controlled. Opto-isolators can provide voltage isolation in excess of 3 kΩ. The serial loading structure of the AD7249 makes it ideal for opto-isolated interfaces as the number of interface lines is kept to a minimum.

Figure 16 shows a 2-channel isolated interface using the AD7249.

The sequence of events to program the output channels is as follows.

1. Take the $\overline{SYNC}$ line low.
2. Transmit the 16-bit word for DAC A (DB 12 of the 16 bit data word selects the DAC, DB12 = 0 to select DAC A) and bring the $\overline{SYNC}$ line high after the 16 bits have been transmitted.
3. Bring $\overline{SYNC}$ line low again and transmit 16 bits for DAC B, bring $\overline{SYNC}$ back high at end of transmission.
4. Pulse the $\overline{LDAC}$ line low. This updates both output channels simultaneously on the falling edge of $\overline{LDAC}$.

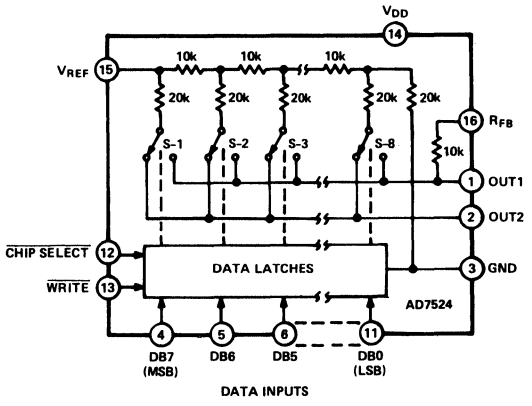
FEATURES
Microprocessor Compatible (6800, 8085, Z80, etc.)
TTL/CMOS Compatible Inputs
On-Chip Data Latches
End Point Linearity
Low Power Consumption
Monotonicity Guaranteed (Full Temperature Range)
Latch Free (No Protection Schottky Required)

APPLICATIONS
Microprocessor Controlled Gain Circuits
Microprocessor Controlled Attenuator Circuits
Microprocessor Controlled Function Generation
Precision AGC Circuits
Bus Structured Instruments

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7524 is a low cost, 8-bit monolithic CMOS DAC designed for direct interface to most microprocessors.

Basically an 8-bit DAC with input latches, the AD7524's load cycle is similar to the "write" cycle of a random access memory. Using an advanced thin-film on CMOS fabrication process, the AD7524 provides accuracy to 1/8LSB with a typical power dissipation of less than 10 milliwatts.

A newly improved design eliminates the protection Schottky previously required and guarantees TTL compatibility when using a +5V supply. Loading speed has been increased for compatibility with most microprocessors.

Featuring operation from +5V to +15V, the AD7524 interfaces directly to most microprocessor buses or output ports.

Excellent multiplying characteristics (2- or 4-quadrant) make the AD7524 an ideal choice for many microprocessor controlled gain setting and signal control applications.

ORDERING GUIDE

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

3

CAUTION:

ESD (Electro-Static-Discharge) sensitive device. The digital control inputs are Zener protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY: A measure of the deviation from a straight line through the end points of the DAC transfer function. Normally expressed as a percentage of full scale range. For the AD7524 DAC, this holds true over the entire V_{REF} range.

RESOLUTION: Value of the LSB. For example, a unipolar converter with n bits has a resolution of $(2^{-n})(V_{REF})$. A bipolar converter of n bits has a resolution of $[2^{-(n-1)}][V_{REF}]$. Resolution in no way implies linearity.

GAIN ERROR: Gain Error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in LSBs. Gain Error is adjustable to zero with an external potentiometer.

FEEDTHROUGH ERROR: Error caused by capacitive coupling from V_{REF} to output with all switches OFF.

OUTPUT CAPACITANCE: Capacity from OUT1 and OUT2 terminals to ground.

OUTPUT LEAKAGE CURRENT: Current which appears on OUT1 terminal with all digital inputs LOW or on OUT2 terminal when all inputs are HIGH. This is an error current which contributes an offset voltage at the amplifier output.

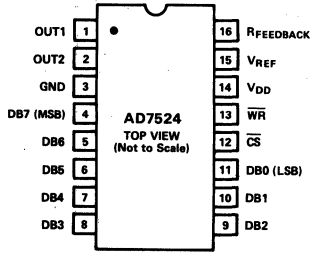
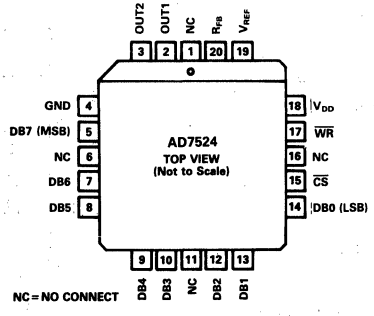
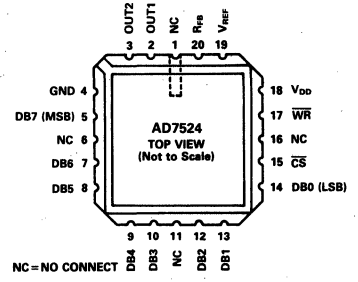
DIP, SOIC



PLCC



LCCC



CIRCUIT DESCRIPTION

CIRCUIT INFORMATION

The AD7524, an 8-bit multiplying D/A converter, consists of a highly stable thin film R-2R ladder and eight N-channel current switches on a monolithic chip. Most applications require the addition of only an output operational amplifier and a voltage or current reference.

The simplified D/A circuit is shown in Figure 1. An inverted R-2R ladder structure is used – that is, the binarily weighted currents are switched between the OUT1 and OUT2 bus lines, thus maintaining a constant current in each ladder leg independent of the switch state.

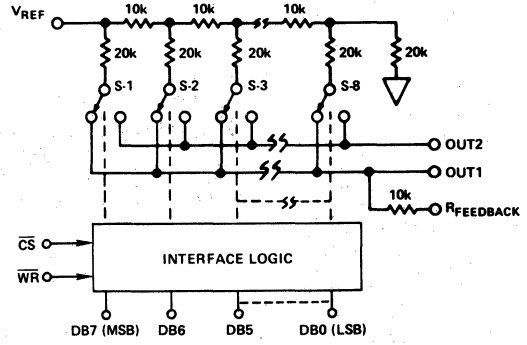


Figure 1. AD7524 Functional Diagram

EQUIVALENT CIRCUIT ANALYSIS

The equivalent circuit for all digital inputs LOW is shown in Figures 2. In Figure 2 with all digital inputs LOW, the reference current is switched to OUT2. The current source $I_{LEAKAGE}$ is composed of surface and junction leakages to the substrate while the $\frac{1}{256}$ current source represents a constant 1-bit current drain through the termination resistor on the R-2R ladder. The "ON" capacitance of the output N-channel switches is 120pF, as shown on the OUT2 terminal. The "OFF" switch capacitance is 30pF, as shown on the OUT1 terminal. Analysis of the circuit for all digital inputs high is similar to Figure 2 however, the "ON" switches are now on terminal OUT1, hence the 120pF appears at that terminal.

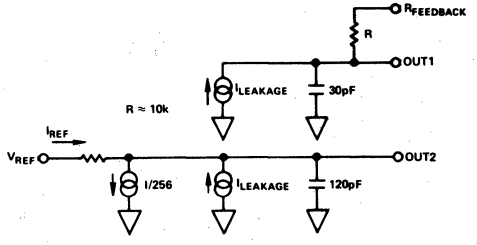

Figure 2. AD7524 DAC Equivalent Circuit – All Digital Inputs Low

INTERFACE LOGIC INFORMATION

MODE SELECTION

AD7524 mode selection is controlled by the $\overline{CS}$ and $\overline{WR}$ inputs.

WRITE MODE

When $\overline{CS}$ and $\overline{WR}$ are both LOW, the AD7524 is in the WRITE mode, and the AD7524 analog output responds to data activity at the DB0–DB7 data bus inputs. In this mode, the AD7524 acts like a nonlatched input D/A converter.

HOLD MODE

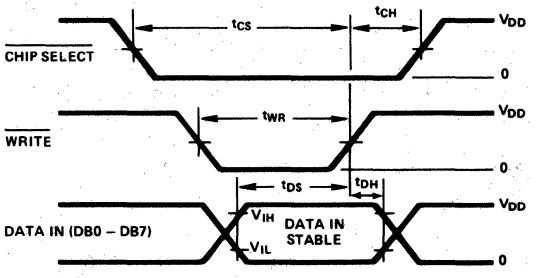
When either $\overline{CS}$ or $\overline{WR}$ is HIGH, the AD7524 is in the HOLD mode. The AD7524 analog output holds the value corresponding to the last digital input present at DB0–DB7 prior to $\overline{WR}$ or $\overline{CS}$ assuming the HIGH state.

MODE SELECTION TABLE

$\overline{CS}$	$\overline{WR}$	MODE	DAC RESPONSE
L	L	Write	DAC responds to data bus (DB0 – DB7) inputs
H	X	Hold	Data bus (DB0 – DB7) is locked out;
X	H	Hold	DAC holds last data present when $\overline{WR}$ or $\overline{CS}$ assumed HIGH state.

L = Low State, H = High State, X = Don't Care.

WRITE CYCLE TIMING DIAGRAM



NOTES:
1. All input signal rise and fall times measured from 10% to 90% of V_{DD}. V_{DD} = +5V, $t_r = t_f$ = 20ns; V_{DD} = +15V, $t_r = t_f$ = 40ns.
2. Timing Measurement Reference level is $\frac{V_{IH} + V_{IL}}{2}$
3. $t_{DS} + t_{DH}$ is approximately constant at 145ns min at +25°C, V_{DD} = +5V and t_{WT} = 170ns min. The AD7524 is specified for a minimum t_{DH} of 10ns, however, in applications where $t_{DH} > 10$ns, t_{DS} may be reduced accordingly up to the limit t_{DS} = 65ns, t_{DH} = 80ns.

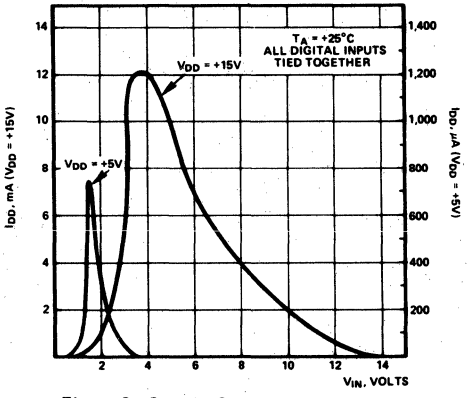


Figure 3. Supply Current vs. Logic Level

Typical plots of supply current, I_{DD}, versus logic input voltage, V_{IN}, for V_{DD} = +5V and V_{DD} = +15V are shown above.

CMOS Dual 8-Bit Buffered Multiplying DAC

AD7528

FEATURES
On-Chip Latches for Both DACs
+5V to +15V Operation

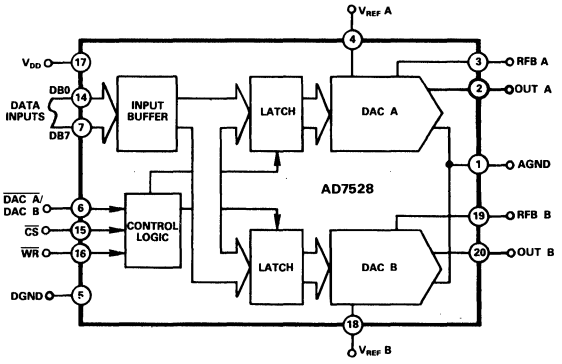
Four Quadrant Multiplication
TTL/CMOS Compatible
Latch Free (Protection Schottkys not Required)

APPLICATIONS
Digital Control of:
Gain/Attenuation
Filter Parameters
Stereo Audio Circuits
X–Y Graphics

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7528 is a monolithic dual 8-bit digital/analog converter featuring excellent DAC-to-DAC matching. It is available in skinny 0.3″ wide 20-pin DIPs and in 20-terminal surface mount packages.

Separate on-chip latches are provided for each DAC to allow easy microprocessor interface.

Data is transferred into either of the two DAC data latches via a common 8-bit TTL/CMOS compatible input port. Control input $\overline{\text{DAC A}}$/DAC B determines which DAC is to be loaded. The AD7528's load cycle is similar to the write cycle of a random access memory and the device is bus compatible with most 8-bit microprocessors, including 6800, 8080, 8085, Z80.

The device operates from a +5V to +15V power supply, dissipating only 20mW of power.

Both DACs offer excellent four quadrant multiplication characteristics with a separate reference input and feedback resistor for each DAC.

PRODUCT HIGHLIGHTS

1. DAC to DAC matching: since both of the AD7528 DACs are fabricated at the same time on the same chip, precise matching and tracking between DAC A and DAC B is inherent.The AD7528's matched CMOS DACs make a whole new range of applications circuits possible, particularly in the audio, graphics and process control areas.
2. Small package size: combining the inputs to the on-chip DAC latches into a common data bus and adding a $\overline{\text{DAC A}}$/DAC B select line has allowed the AD7528 to be packaged in either a small 20-pin DIP, SOIC, PLCC or LCCC.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Temperature Ranges are J, K, L Versions: −40°C to +85°C
A, B, C Versions: −40°C to +85°C
S, T, U Versions: −55°C to +125°C
[2]Specification applies to both DACs in AD7528.
[3]Logic inputs are MOS Gates. Typical input current (+25°C) is less than 1nA.
[4]Guaranteed by design but not production tested.
[5]These characteristics are for design guidance only and are not subject to test.
[6]Feedthrough can be further reduced by connecting the metal lid on the ceramic package (suffix D) to DGND.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

(T_A = +25°C unless otherwise noted)

V_{DD} to AGND	0V, +17V
V_{DD} to DGND	0V, +17V
AGND to DGND	V_{DD} +0.3V
DGND to AGND	V_{DD} +0.3V
Digital Input Voltage to DGND	−0.3V, V_{DD} +0.3V
V_{PIN2}, V_{PIN20} to AGND	−0.3V, V_{DD} +0.3V
V_{REF} A, V_{REF} B to AGND	±25V
V_{RFB} A, V_{RFB} B to AGND	±25V
Power Dissipation (Any Package) to +75°C	450mW
Derates above +75°C by	6mW/°C
Operating Temperature Range	
Commercial (J, K, L) Grades	−40°C to +85°C
Industrial (A, B, C) Grades	−40°C to +85°C
Extended (S, T, U) Grades	−55°C to +125°C
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10 secs.)	+300°C

CAUTION:

1. ESD sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.
2. Do not insert this device into powered sockets. Remove power before insertion or removal.

TERMINOLOGY

Relative Accuracy:
Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero and full scale and is normally expressed in LSBs or as a percentage of full scale reading.

ORDERING GUIDE[1]

Model[2]	Temperature Range	Relative Accuracy	Gain Error	Package Option[3]
AD7528JN	−40°C to +85°C	±1LSB	±4LSB	N-20
AD7528KN	−40°C to +85°C	±1/2LSB	±2LSB	N-20
AD7528LN	−40°C to +85°C	±1/2LSB	±1LSB	N-20
AD7528JP	−40°C to +85°C	±1LSB	±4LSB	P-20A
AD7528KP	−40°C to +85°C	±1/2LSB	±2LSB	P-20A

AD7528UE	−55°C to +125°C	±1/2LSB	±1LSB	E-20A

NOTES
[1]Analog Devices reserves the right to ship side-brazed ceramic in lieu of cerdip. Parts will be marked with cerdip designator "Q."
[2]Processing to MIL-STD-883C, Class B is available. To order, add suffix "/883B" to part number. For further information, see Analog Devices' 1990 Military Products Databook.
[3]E = Leadless Ceramic Chip Carrier; N = Plastic DIP; P = Plastic Leaded Chip Carrier; Q = Cerdip; R = SOIC. For outline information see Package Information section.

Differential Nonlinearity:
Differential nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range ensures monotonicity.

Gain Error:
Gain error or full-scale error is a measure of the output error between an ideal DAC and the actual device output. For the AD7528, ideal maximum output is V_{REF} − 1LSB. Gain error of both DACs is adjustable to zero with external resistance.

Output Capacitance:
Capacitance from OUT A or OUT B to AGND.

Digital to Analog Glitch Impulse:
The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage signal. Glitch impulse is measured with V_{REF} A, V_{REF} B = AGND.

Propagation Delay:
This is a measure of the internal delays of the circuit and is defined as the time from a digital input change to the analog output current reaching 90% of its final value.

Channel-to-Channel Isolation:
The proportion of input signal from one DAC's reference input which appears at the output of the other DAC, expressed as a ratio in dB.

Digital Crosstalk:
The glitch energy transferred to the output of one converter due to a change in digital input code to the other converter. Specified in nV secs.

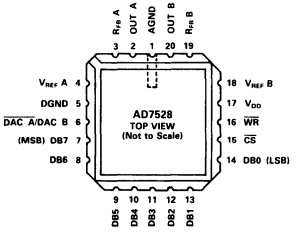
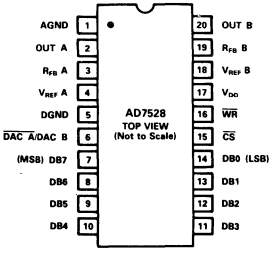
LCCC



DIP, SOIC



INTERFACE LOGIC INFORMATION

DAC Selection:

Both DAC latches share a common 8-bit input port. The control input $\overline{\text{DAC A}}$/DAC B selects which DAC can accept data from the input port.

Mode Selection:

Inputs $\overline{\text{CS}}$ and $\overline{\text{WR}}$ control the operating mode of the selected DAC. See Mode Selection Table below.

Write Mode:

When $\overline{\text{CS}}$ and $\overline{\text{WR}}$ are both low the selected DAC is in the write mode. The input data latches of the selected DAC are transparent and its analog output responds to activity on DB0–DB7.

Hold Mode:

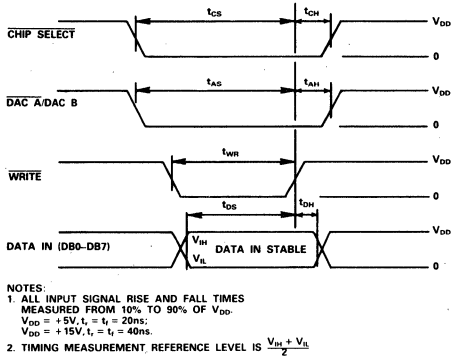
The selected DAC latch retains the data which was present on DB0–DB7 just prior to $\overline{\text{CS}}$ or $\overline{\text{WR}}$ assuming a high state. Both analog outputs remain at the values corresponding to the data in their respective latches.

$\overline{\text{DAC A}}$/DAC B	$\overline{\text{CS}}$	$\overline{\text{WR}}$	DAC A	DAC B
L	L	L	WRITE	HOLD
H	L	L	HOLD	WRITE
X	H	X	HOLD	HOLD
X	X	H	HOLD	HOLD

L = Low State H = High State X = Don't Care

Mode Selection Table

WRITE CYCLE TIMING DIAGRAM



NOTES:
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% TO 90% OF V_{DD}. V_{DD} = +5V, $t_r = t_f$ = 20ns; V_{DD} = +15V, $t_r = t_f$ = 40ns.
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$

CIRCUIT INFORMATION–D/A SECTION

The AD7528 contains two identical 8-bit multiplying D/A converters, DAC A and DAC B. Each DAC consists of a highly stable thin film R-2R ladder and eight N-channel current steering switches. A simplified D/A circuit for DAC A is shown in Figure 1. An inverted R-2R ladder structure is used, that is, binary weighted currents are switched between the DAC output and AGND thus maintaining fixed currents in each ladder leg independent of switch state.

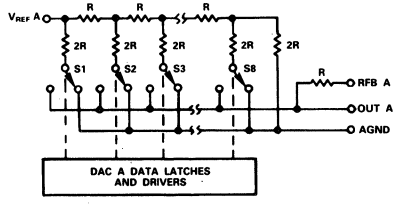


Figure 1. Simplified Functional Circuit for DAC A

EQUIVALENT CIRCUIT ANALYSIS

Figure 2 shows an approximate equivalent circuit for one of the AD7528's D/A converters, in this case DAC A. A similar equivalent circuit can be drawn for DAC B. Note that AGND (Pin 1) is common for both DAC A and DAC B.

The current source $I_{LEAKAGE}$ is composed of surface and junction leakages and, as with most semiconductor devices, approximately doubles every 10°C. The resistor R_O as shown in Figure 2 is the equivalent output resistance of the device which varies with input code (excluding all 0's code) from 0.8R to 2R. R is typically 11kΩ. C_{OUT} is the capacitance due to the N-channel switches and varies from about 50pF to 120pF depending upon the digital input. g(V_{REF} A, N) is the Thevenin equivalent voltage generator due to the reference input voltage V_{REF} A and the transfer function of the R-2R ladder.

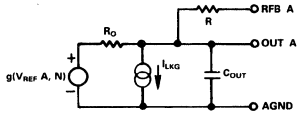

Figure 2. Equivalent Analog Output Circuit of DAC A

For further information on CMOS multiplying D/A converters refer to "Appplication Guide to CMOS Multiplying D/A Converters" available from Analog Devices, Publication Number G479–15–8/78.

CIRCUIT INFORMATION–DIGITAL SECTION

The input buffers are simple CMOS inverters designed such that when the AD7528 is operated with V_{DD} = 5V, the buffer converts TTL input levels (2.4V and 0.8V) into CMOS logic levels. When V_{IN} is in the region of 2.0 volts to 3.5 volts the input buffers operate in their linear region and pass a quiescent current, see Figure 3. To minimize power supply currents it is recommended that the digital input voltages be as close to the supply rails (V_{DD} and DGND) as is practically possible.

The AD7528 may be operated with any supply voltage in the range $5 \leq V_{DD} \leq 15$ volts. With V_{DD} = +15V the input logic levels are CMOS compatible only, i.e., 1.5V and 13.5V.

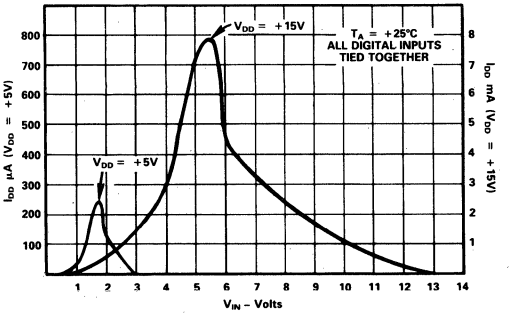

Figure 3. Typical Plots of Supply Current, I_{DD} vs. Logic Input Voltage V_{IN}, for V_{DD} = +5V and +15V

LC²MOS Dual 12-Bit DACs

AD7537/AD7547

FEATURES

Two 12-Bit DACs in One Package
DAC Ladder Resistance Matching: 0.5%
Space Saving Skinny DIP and Surface Mount Packages
4-Quadrant Multiplication
Low Gain Error (1LSB max Over Temperature)
Byte Loading Structure
Fast Interface Timing

APPLICATIONS

Automatic Test Equipment
Programmable Filters
Audio Applications
Synchro Applications
Process Control

GENERAL DESCRIPTION

The AD7537/AD7547 contains two 12-bit current output DACs on one monolithic chip. Also on-chip are the level shifters, data registers and control logic for easy microprocessor interfacing. There are 12 data inputs. The AD7537 has a 2-byte loading structure making it compatible with 8-bit processor systems. The AD7547 has a 12-bit parallel loading structure for use in 16-bit systems.

The D/A converters provide 4-quadrant multiplication capabilities with separate reference inputs and feedback resistors. Monolithic construction ensures that thermal and gain error tracking is excellent. Twelve-bit monotonicity is guaranteed for both DACs over the full temperature range.

The DACs are manufactured using the Linear Compatible CMOS (LC²MOS) process. This allows fast digital logic and precision linear circuitry to be fabricated on the same die.

PRODUCT HIGHLIGHTS

1. DAC to DAC Matching
   Since both DACs are fabricated on the same chip, precise matching and tracking is inherent. Many applications which are not practical using two discrete DACs are now possible. Typical matching: 0.5%.
2. Wide Power Supply Tolerance
   The device operates on a +12V to +15V V_{DD}, with ±10% tolerance on this nominal figure. All specifications are guaranteed over this range.

AC PERFORMANCE CHARACTERISTICS

These characteristics are included for Design Guidance only and are not subject to test.

(V_{DD} = +12V to +15V; V_{REFA} = V_{REFB} = +10V, I_{OUTA} = I_{OUTB} = AGND = 0V. Output Amplifiers are AD644 except where stated.)

Parameter	T_A = +25°C	T_A = T_{min}, T_{max}	Units	Test Conditions/Comments
Output Current Settling Time	1.5	–	μs max	To 0.01% of full-scale range. I_{OUT} load = 100Ω, C_{EXT} = 13pF. DAC output measured from rising edge of $\overline{WR}$. Typical Value of Settling Time is 0.8μs.
Digital-to-Analog Glitch Impulse	7	–	nV-s typ	Measured with V_{REFA} = V_{REFB} = 0V. I_{OUTA}, I_{OUTB} load = 100Ω, C_{EXT} = 13pF. DAC registers alternately loaded with all 0's and all 1's.
AC Feedthrough[4]				
V_{REFA} to I_{OUTA}	−70	−65	dB max	V_{REFA}, V_{REFB} = 20Vp-p 10kHz sinewave. DAC
V_{REFB} to I_{OUTB}	−70	−65	dB max	registers loaded with all 0's.
Power Supply Rejection ΔGain/ΔV_{DD}	±0.01	±0.02	% per % max	ΔV_{DD} = V_{DD} max − V_{DD} min
Output Capacitance				
C_{OUTA}	70	70	pF max	DAC A, DAC B loaded with all 0's.
C_{OUTB}	70	70	pF max	
C_{OUTA}	140	140	pF max	DAC A, DAC B loaded with all 1's.
C_{OUTB}	140	140	pF max	
Channel-to-Channel Isolation				
V_{REFA} to I_{OUTB}	−84	–	dB typ	V_{REFA} = 20V p-p 10kHz sinewave, V_{REFB} = 0V. Both DACs loaded with all 1's.
V_{REFB} to I_{OUTA}	−84	–	dB typ	V_{REFB} = 20V p-p 10kHz sinewave, V_{REFA} = 0V. Both DACs loaded with all 1's.
Digital Crosstalk	7	–	nV-s typ	Measured for a Code Transition of all 0's to all 1's. I_{OUTA}, I_{OUTB} Load = 100Ω, C_{EXT} = 13pF
Output Noise Voltage Density (10Hz-100kHz)	25	–	nV/√Hz typ	Measured between R_{FBA} and I_{OUTA} or R_{FBB} and I_{OUTB}. Frequency of measurement is 10Hz–100kHz.
Total Harmonic Distortion	−82	–	dB typ	V_{IN} = 6V rms, 1kHz. Both DACs loaded with all 1's.

NOTES

[1]Temperature range as follows: J, K, L Versions: −40°C to +85°C.
A, B, C Versions: −40°C to +85°C.
S, T, U Versions: −55°C to +125°C.

[2]Sample tested at 25°C to ensure compliance.

[3]Functional at V_{DD} = 5V with degraded specifications.

[4]Pin 12 (DGND) on ceramic DIPs is connected to lid.

Specifications subject to change without notice.

AD7537 TIMING CHARACTERISTICS (V_{DD} = 10.8V to 16.5V, $V_{REFA} = V_{REFB}$ = +10V, I_{OUTA} = AGNDA = 0V, I_{OUTB} = AGNDB = 0V).

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

22	V_{REFB}	Reference input to DACB.
23	R_{FBB}	Feedback resistor of DACB.
24	I_{OUTB}	Current output terminal of DACB.

CIRCUIT INFORMATION

D/A SECTION

The AD7537/AD7547 contains two identical 12-bit multiplying D/A converters. Each DAC consists of a highly stable R-2R ladder and 12 N-channel current steering switches. Figure 3 shows a simplified D/A circuit for DAC A. In the R-2R ladder, binary weighted currents are steered between I_{OUTA} and AGND. The current flowing in each ladder leg is constant, irrespective of switch state. The feedback resistor R_{FBA} is used with an op-amp to convert the current flowing in I_{OUTA} to a voltage output.

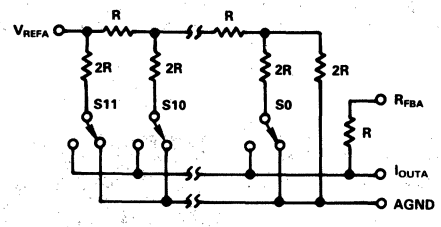

Figure 3. Simplified Circuit Diagram for DACA

EQUIVALENT CIRCUIT ANALYSIS

Figure 4 shows the equivalent circuit for one of the D/A converters (DAC A) in the AD7537/AD7547. A similar equivalent circuit can be drawn for DACB. Note that AGND is common to both DAC A and DAC B.

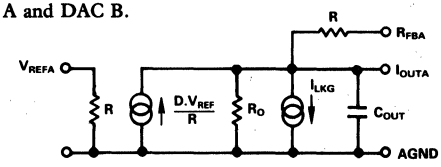

Figure 4. Equivalent Analog Circuit for DACA

C_{OUT} is the output capacitance due to the N-channel switches and varies from about 50pF to 150pF with digital input code. The current source I_{LKG} is composed of surface and junction leakages and approximately doubles every 10°C. R_O is the equivalent output resistance of the device which varies with input code.

DIGITAL CIRCUIT INFORMATION

The digital inputs are designed to be both TTL and 5V CMOS compatible. All logic inputs are static-protected MOS gates with typical input currents of less than 1nA.

LC²MOS
µP-Compatible 14-Bit DAC

AD7538

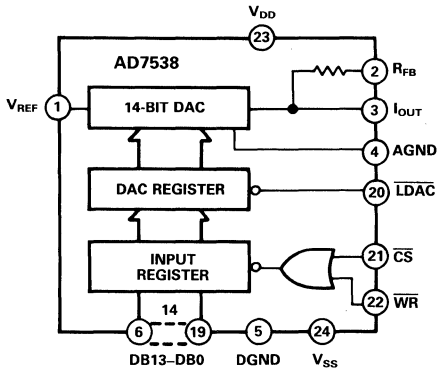
FEATURES

All Grades 14-Bit Monotonic over the Full Temperature Range
Low Cost 14-Bit Upgrade for 12-Bit Systems
14-Bit Parallel Load with Double Buffered Inputs
Small 24-Pin, 0.3″ DIP and SOIC
Low Output Leakage (<20nA) over the Full Temperature Range

APPLICATIONS

Microprocessor Based Control Systems
Digital Audio
Precision Servo Control
Control and Measurement in High Temperature Environments

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7538 is a 14-bit monolithic CMOS D/A converter which uses laser trimmed thin-film resistors to achieve excellent linearity.

The DAC is loaded by a single 14-bit wide word using standard Chip Select and Memory Write Logic. Double buffering, which is optional using $\overline{\text{LDAC}}$, allows simultaneous update in a system containing multiple AD7538s.

A novel low leakage configuration (U.S. Patent No. 4,590,456) enables the AD7538 to exhibit excellent output leakage current characteristics over the specified temperature range.

The AD7538 is manufactured using the Linear Compatible CMOS (LC²MOS) process. It is speed compatible with most microprocessors and accepts TTL or CMOS logic level inputs.

PRODUCT HIGHLIGHTS

1. Guaranteed Monotonicity
   The AD7538 is guaranteed monotonic to 14-bits over the full temperature range for all grades.
2. Low Cost
   The AD7538, with its 14-bit dynamic range, affords a low cost solution for 12-bit system upgrades.
3. Small Package Size
   The AD7538 is packaged in a small 24-pin, 0.3″ DIP and a 24-pin SOIC.
4. Low Output Leakage
   By tying V_{SS} (Pin 24) to a negative voltage, it is possible to achieve a low output leakage current at high temperatures.
5. Wide Power Supply Tolerance
   The device operates on a +12 to +15V V_{DD}, with a ±5% tolerance on this nominal figure. All specifications are guaranteed over this range.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

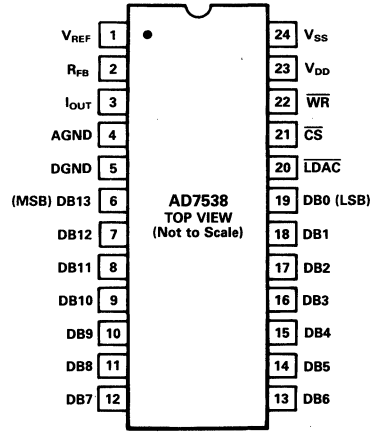
PIN CONFIGURATION

DIP, SOIC



TERMINOLOGY

RELATIVE ACCURACY
Relative accuracy or end-point nonlinearity is a measure of the maximum deviation from a straight line passing through the end-points of the DAC transfer function. It is measured after adjusting for zero error and full-scale error and is normally expressed in Least Significant Bits or as a percentage of full-scale reading.

DIFFERENTIAL NONLINEARITY
Differential nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range ensures monotonicity.

GAIN ERROR
Gain error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in Least Significant Bits. Gain error is adjustable to zero with an external potentiometer.

DIGITAL-TO-ANALOG GLITCH IMPULSE
The amount of charge injected from the digital inputs to the analog output when the inputs change state is called Digital-to-Analog Glitch Impulse. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage. It is measured with V_{REF} = AGND.

OUTPUT CAPACITANCE
This is the capacitance from I_{OUT} to AGND.

OUTPUT LEAKAGE CURRENT
Output Leakage Current is current which appears at I_{OUT} with the DAC register loaded to all 0s.

MULTIPLYING FEEDTHROUGH ERROR
This is the ac error due to capacitive feedthrough from V_{REF} terminal to I_{OUT} with DAC register loaded to all zeros.

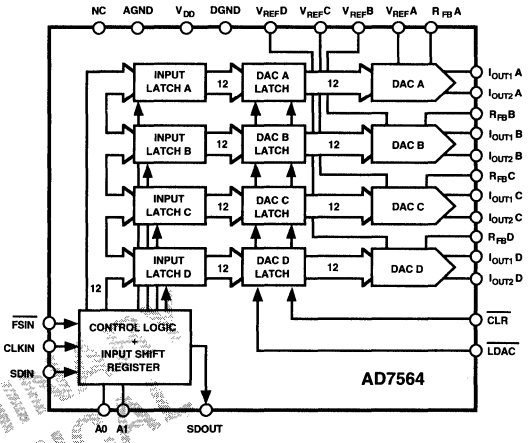
General Purpose Test Equipment

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7564 contains four 12-bit DACs in one monolithic device. The DACs are standard current output with separate V_{REF}, I_{OUT1}, I_{OUT2} and R_{FB} terminals. These DACs operate from a single +5 V supply (Normal Mode) and a single +3.3 V to +5 V supply (Biased Mode).

The AD7564 is a serial input device. Data is loaded using $\overline{FSIN}$, CLKIN and SDIN. Two address pins A0 and A1 set up a device address, and this feature may be used to simplify device loading in a multi-DAC environment. Alternatively, A0 and A1 can be ignored and the serial out capability used to configure a daisy-chained system.

All DACs can be simultaneously updated using the asynchronous $\overline{LDAC}$ input, and they can be cleared by asserting the asynchronous $\overline{CLR}$ input.

The device is packaged in 28-pin SOIC, SSOP and DIP packages.

PRODUCT HIGHLIGHTS

1. The AD7564 contains four 12-bit current output DACs with separate V_{REF} inputs.
2. The AD7564 can be operated from a single +5 V supply (Normal Mode) or a single +3.3 V to +5 V supply (Biased Mode).
3. Simultaneous update capability and reset function are available.
4. The AD7564 features a fast, versatile serial interface compatible with all modern microprocessors and microcomputers.

NOTES
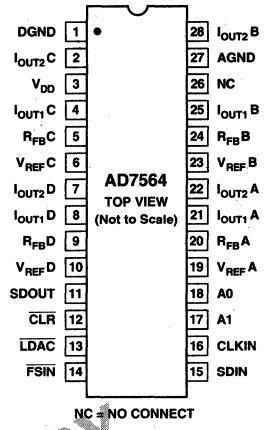
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Transient currents of up to 100 mA will not cause SCR latch-up.

PIN CONFIGURATION

DIP, SOIC and SSOP Packages



NC = NO CONNECT

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7564 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN DESCRIPTIONS

Pin Number	Mnemonic	Description
1	DGND	Digital Ground.
2	$I_{OUT2}C$	I_{OUT2} terminal for DAC C. This should normally connect to the signal ground of the system.
3	V_{DD}	Positive power supply. This is +5 V ± 5%.
4	$I_{OUT1}C$	I_{OUT1} terminal for DAC C.
5	$R_{FB}C$	Feedback resistor for DAC C.
6	$V_{REF}C$	DAC C reference input.
7	$I_{OUT2}D$	I_{OUT2} terminal for DAC D. This should normally connect to the signal ground of the system.
8	$I_{OUT1}D$	I_{OUT1} terminal for DAC D.
9	$R_{FB}D$	Feedback resistor for DAC D.
10	$V_{REF}D$	DAC D reference input.
11	SDOUT	This shift register output allows multiple devices to be connected in a daisy chain configuration.
12	$\overline{CLR}$	Asynchronous $\overline{CLR}$ input. When this input is taken low, all DAC latches are loaded with all 0s.
13	$\overline{LDAC}$	Asynchronous LDAC input. When this input is taken low, all DAC latches are simultaneously updated with the contents of the input latches.
14	$\overline{FSIN}$	Level-triggered control input (active low). This is the frame synchronization signal for the input data. When $\overline{FSIN}$ goes low, it enables the input shift register, and data is transferred on the falling edges of CLKIN. If the address bits are valid, the 12-bit DAC data is transferred to the appropriate input latch on the sixteenth falling edge after $\overline{FSIN}$ goes low.
15	SDIN	Serial data input. The device accepts a 16-bit word. DB0 and DB1 are DAC select bits. DB2 and DB3 are device address bits. DB4 to DB15 contain the 12-bit data to be loaded to the selected DAC.
16	CLKIN	Clock Input. Data is clocked into the input shift register on the falling edges of CLKIN.
17	A1	Device address pin. This input in association with A0 gives the device an address. If DB2 and DB3 of the serial input stream do not correspond to this address, the data which follows is ignored and not loaded to any input latch. However, it will appear at SDOUT irrespective of this.
18	A0	Device address pin. This input in association with A1 gives the device an address.
19	$V_{REF}A$	DAC A reference input.
20	$R_{FB}A$	Feedback resistor for DAC A.
21	$I_{OUT1}A$	I_{OUT1} terminal for DAC A.
22	$I_{OUT2}A$	I_{OUT2} terminal for DAC A. This should normally connect to the signal ground of the system.
23	$V_{REF}B$	DAC B reference input.
24	$R_{FB}B$	Feedback resistor for DAC B.
25	$I_{OUT1}B$	I_{OUT1} terminal for DAC B.
26	N/C	No Connect pin.
27	AGND	This pin connects to the back gates of the current steering switches. It should be connected to the signal ground of the system.
28	$I_{OUT2}B$	I_{OUT2} terminal for DAC B. This should normally connect to the signal ground of the system.

TERMINOLOGY

Relative Accuracy
Relative accuracy or endpoint linearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero error and full-scale error and is normally expressed in Least Significant Bits or as a percentage of full-scale reading.

Differential Nonlinearity
Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of 1 LSB maximum ensures monotonicity.

Gain Error
Gain error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in Least Significant Bits. Gain error is adjustable to zero with an external potentiometer.

Output Leakage Current
Output leakage current is current which flows in the DAC ladder switches when these are turned off. For the I_{OUT1} terminal, it can be measured by loading all 0s to the DAC and be measured by loading all 0s to the DAC and measuring the I_{OUT1} current. Minimum current will flow in the I_{OUT2} line when the DAC is loaded with all 1s. This is a combination of the switch leakage current and the ladder termination resistor current. The I_{OUT2} leakage current is typically equal to that in I_{OUT1}.

Output Capacitance
This is the capacitance from the I_{OUT1} pin to AGND.

Output Voltage Settling Time
This is the amount of time it takes for the output to settle to a specified level for a full-scale input change. For the AD7564, it is specified with the AD843 as the output op amp.

Digital to Analog Glitch Impulse
This is the amount of charge injected into the analog output when the inputs change state. It is normally specified as the area of the glitch in either pA-secs or nV-secs, depending upon whether the glitch is measured as a current or voltage signal. It is measured with the reference input connected to AGND and the digital inputs toggled between all 1s and all 0s.

AC Feedthrough Error
This is the error due to capacitive feedthrough from the DAC reference input to the DAC I_{OUT} terminal, when all 0s are loaded in the DAC.

Channel-to-Channel Isolation
Channel-to-channel isolation refers to the proportion of input signal from one DAC's reference input which appears at the output of any other DAC in the device and is expressed in dBs.

Digital Crosstalk
The glitch impulse transferred to the output of one converter due to a change in digital input code to the other converter is defined as the Digital Crosstalk and is specified in nV-secs.

Digital Feedthrough
When the device is not selected, high frequency logic activity on the device digital inputs is capacitively coupled through the device to show up at on the I_{OUT} pin and subsequently on the op amp output. This noise is digital feedthrough.

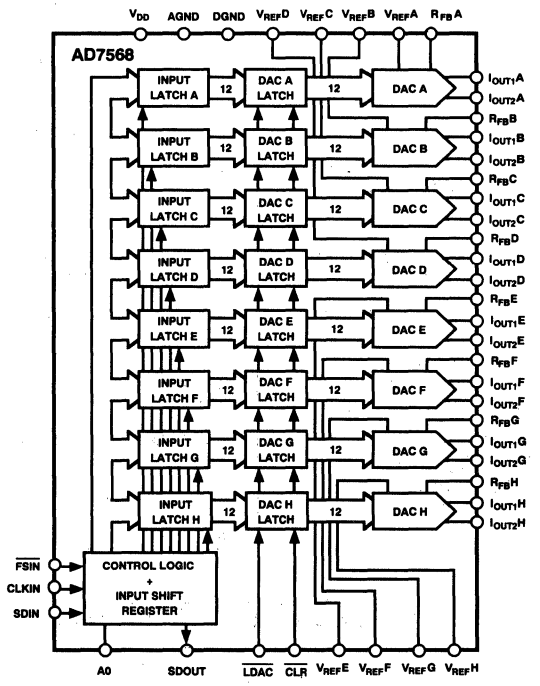
FEATURES

- Eight 12-Bit DACs in One Package
- 4-Quadrant Multiplication
- Separate References
- Single +5 V Supply
- Low Power: 1 mW
- Versatile Serial Interface
- Simultaneous Update Capability
- Reset Function
- 44-Pin PQFP and PLCC

APPLICATIONS

- Process Control
- Automatic Test Equipment
- General Purpose Instrumentation

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7568 contains eight 12-bit DACs in one monolithic device. The DACs are standard current output with separate V_{REF}, I_{OUT1}, I_{OUT2} and R_{FB} terminals.

The AD7568 is a serial input device. Data is loaded using $\overline{FSIN}$, CLKIN and SDIN. One address pin, A0, sets up a device address, and this feature may be used to simplify device loading in a multi-DAC environment.

All DACs can be simultaneously updated using the asynchronous $\overline{LDAC}$ input and they can be cleared by asserting the asynchronous $\overline{CLR}$ input.

The AD7568 is housed in a space-saving 44-pin plastic quad flatpack and 44-lead PLCC.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Transient currents of up to 100 mA will not cause SCR latch-up.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

Relative Accuracy
Relative Accuracy or endpoint linearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero error and full-scale error and is normally expressed in Least Significant Bits or as a percentage or full-scale reading.

Differential Nonlinearity
Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of 1 LSB maximum ensures monotonicity.

Gain Error
Gain Error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in Least Significant Bits. Gain error is adjustable to zero with an external potentiometer.

Output Leakage Current
Output leakage current is current which flows in the DAC ladder switches when these are turned off. For the I_{OUT1} terminal, it can be measured by loading all 0s to the DAC and measuring the I_{OUT1} current. Minimum current will flow in the I_{OUT2} line when the DAC is loaded with all 1s. This is a combination of the switch leakage current and the ladder termination resistor current. The I_{OUT2} leakage current is typically equal to that in I_{OUT1}.

Output Capacitance
This is the capacitance from the I_{OUT1} pin to AGND.

Output Voltage Settling Time
This is the amount of time it takes for the output to settle to a specified level for a full-scale input change. For the AD7568, it is specified with the AD843 as the output op amp.

Digital to Analog Glitch Impulse
This is the amount of charge injected into the analog output when the inputs change state. It is normally specified as the area of the glitch in either pA-secs or nV-secs, depending upon whether the glitch is measured as a current or voltage signal. It is measured with the reference input connected to AGND and the digital inputs toggled between all 1s and all 0s.

AC Feedthrough Error
This is the error due to capacitive feedthrough from the DAC reference input to the DAC I_{OUT} terminal, when all 0s are loaded in the DAC.

Channel-to-Channel Isolation
Channel-to-channel isolation refers to the proportion of input signal from one DAC's reference input which appears at the output of any other DAC in the device and is expressed in dBs.

Digital Crosstalk
The glitch impulse transferred to the output of one converter due to a change in digital input code to the other converter is defined as the Digital Crosstalk and is specified in nV-secs.

Digital Feedthrough
When the device is not selected, high frequency logic activity on the device digital inputs is capacitively coupled through the device to show up as noise on the I_{OUT} pin and subsequently on the op amp output. This noise is digital feedthrough.

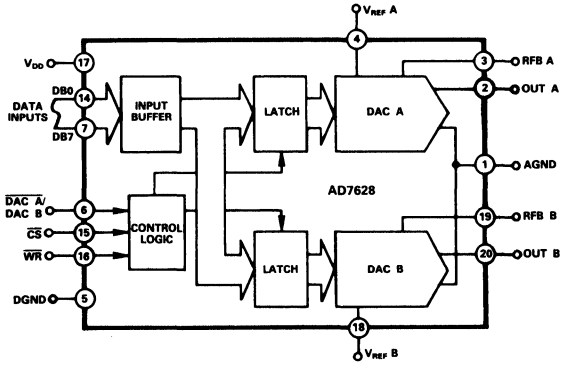
CMOS Dual 8-Bit Buffered Multiplying DAC

AD7628

FEATURES
- On-Chip Latches for Both DACs
- +12V to +15V Operation
- DACs Matched to 1%
- Four Quadrant Multiplication
- TTL/CMOS Compatible from +12V to +15V
- Latch Free (Protection Schottkys not Required)

APPLICATIONS
- Disk Drives
- Programmable Filters
- X-Y Graphics
- Gain/Attenuation

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7628 is a monolithic dual 8-bit digital/analog converter featuring excellent DAC-to-DAC matching. It is available in small 0.3"-wide 20-pin DIPs and in 20-terminal surface mount packages.

Separate on-chip latches are provided for each DAC to allow easy microprocessor interface.

Data is transferred into either of the two DAC data latches via a common 8-bit TTL/CMOS compatible input port. Control input $\overline{\text{DAC A}}$/DAC B determines which DAC is to be loaded. The AD7628's load cycle is similar to the write cycle of a random access memory, and the device is bus compatible with most 8-bit microprocessors, including 6502, 6809, 8085, Z80.

The device operates from a +12V to +15V power supply and is TTL-compatible over this range. Power dissipation is a low 20mW.

Both DACs offer excellent four quadrant multiplication characteristics with a separate reference input and feedback resistor for each DAC.

PRODUCT HIGHLIGHTS

1. DAC to DAC matching: since both of the AD7628 DACs are fabricated at the same time on the same chip, precise matching and tracking between DAC A and DAC B is inherent.The AD7628's matched CMOS DACs make a whole new range of applications circuits possible, particularly in the audio, graphics and process control areas.
2. Small package size: combining the inputs to the on-chip DAC latches into a common data bus and adding a $\overline{\text{DAC A}}$/DAC B select line has allowed the AD7628 to be packaged in a small 20-pin 0.3" wide DIP, 20-pin SOIC, 20-terminal PLCC and 20-terminal LCC.
3. TTL-Compatibility: All digital inputs are TTL-compatible over a +12V to +15V power supply range.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Temperature Ranges are K Version; −40°C to +85°C
B Version; −40°C to +85°C
T Version; −55°C to +125°C
[2]Specification applies to both DACs in AD7628.
[3]Guaranteed by design but not production tested.
[4]Logic inputs are MOS Gates. Typical input current (+25°C) is less than 1nA.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

(T_A = +25°C unless otherwise noted)

V_{DD} to AGND	0V, +17V
V_{DD} to DGND	0V, +17V
AGND to DGND	V_{DD} +0.3V
DGND to AGND	V_{DD} +0.3V
Digital Input Voltage to DGND	−0.3V, V_{DD} +0.3V
V_{PIN2}, V_{PIN20} to AGND	−0.3V, V_{DD} +0.3V
V_{REF} A, V_{REF} B to AGND	±25V
V_{RFB} A, V_{RFB} B to AGND	±25V
Power Dissipation (Any Package) to +75°C	450mW
Derates above +75°C by	6mW/°C
Operating Temperature Range	
Commercial (K) Grades	−40°C to +85°C
Industrial (B) Grades	−40°C to +85°C
Extended (T) Grades	−55°C to +125°C
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10sec)	+300°C

CAUTION:

1. ESD sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.
2. Do not insert this device into powered sockets. Remove power before insertion or removal.

ORDERING GUIDE

Model[1]	Temperature Range	Relative Accuracy	Gain Error	Package Option[2]
AD7628KN	−40°C to +85°C	±1/2LSB	±2LSB	N-20
AD7628KP	−40°C to +85°C	±1/2LSB	±2LSB	P-20A
AD7628KR	−40°C to +85°C	±1/2LSB	±2LSB	R-20
AD7628BQ	−40°C to +85°C	±1/2LSB	±2LSB	Q-20
AD7628TQ	−55°C to +125°C	±1/2LSB	±2LSB	Q-20

TERMINOLOGY

Relative Accuracy:
Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero and full-scale and is normally expressed in LSBs or as a percentage of full-scale reading.

Differential Nonlinearity:
Differential nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range ensures monotonicity.

Gain Error:
Gain error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC latches after offset error has been adjusted out. Gain error of both DACs is adjustable to zero with external resistance.

Output Capacitance:
Capacitance from OUT A or OUT B to AGND.

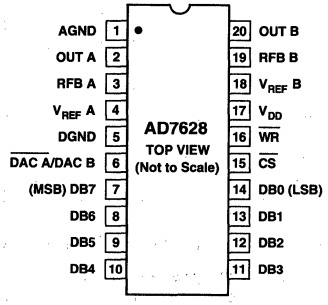
Digital-to-Analog Glitch Impulse:
The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage signal. Glitch impulse is measured with V_{REF} A, V_{REF} B = AGND.

Channel-to-Channel Isolation:
The proportion of input signal from one DAC's reference input which appears at the output of the other DAC, expressed as a ratio in dB.

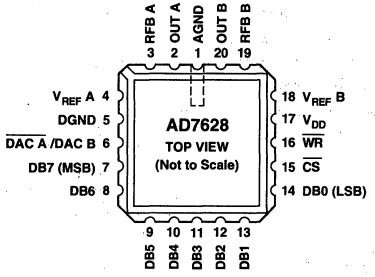
Digital Crosstalk:
The glitch energy transferred to the output of one converter due to a change in digital input code to the other converter. Specified in nV secs.

PIN CONFIGURATIONS

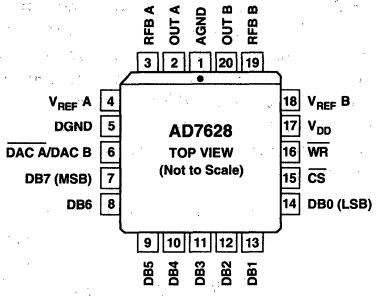
DIP, SOIC



LCCC



PLCC



INTERFACE LOGIC INFORMATION

DAC Selection:

Both DAC latches share a common 8-bit input port. The control input $\overline{DAC\ A}$/DAC B selects which DAC can accept data from the input port.

Mode Selection:

Inputs $\overline{CS}$ and $\overline{WR}$ control the operating mode of the selected DAC. See Mode Selection Table below.

Write Mode:

When $\overline{CS}$ and $\overline{WR}$ are both low the selected DAC is in the write mode. The input data latches of the selected DAC are transparent and its analog output responds to activity on DB0–DB7.

Hold Mode:

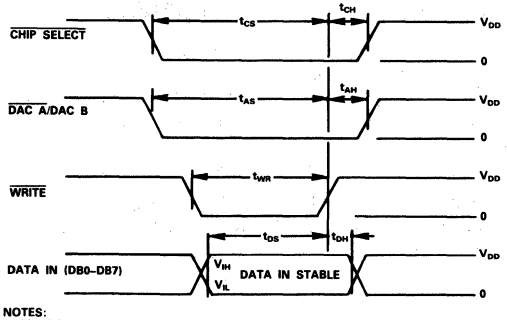
The selected DAC latch retains the data which was present on DB0–DB7 just prior to $\overline{CS}$ or $\overline{WR}$ assuming a high state. Both analog outputs remain at the values corresponding to the data in their respective latches.

$\overline{DAC\ A}$/DAC B	$\overline{CS}$	$\overline{WR}$	DAC A	DAC B
L	L	L	WRITE	HOLD
H	L	L	HOLD	WRITE
X	H	X	HOLD	HOLD
X	X	H	HOLD	HOLD

L = Low State H = High State X = Don't Care

Mode Selection Table

WRITE CYCLE TIMING DIAGRAM



NOTES:
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% TO 90% OF +5V. V_{DD} = +10.8V TO +15.75V, $t_R = t_F$ = 20ns.
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$

CIRCUIT INFORMATION – D/A SECTION

The AD7628 contains two identical 8-bit multiplying D/A converters, DAC A and DAC B. Each DAC consists of a highly stable thin film R-2R ladder and eight N-channel current steering switches. A simplified D/A circuit for DAC A is shown in Figure 1. An inverted R-2R ladder structure is used, that is, binary weighted currents are switched between the DAC output and AGND thus maintaining fixed currents in each ladder leg independent of switch state.

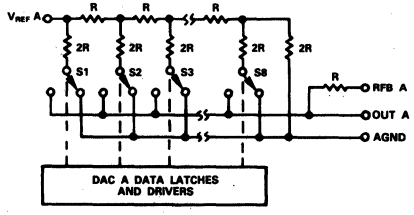


Figure 1. Simplified Functional Circuit for DAC A

EQUIVALENT CIRCUIT ANALYSIS

Figure 2 shows an approximate equivalent circuit for one of the AD7628's D/A converters, in this case DAC A. A similar equivalent circuit can be drawn for DAC B. Note that AGND (Pin 1) is common for both DAC A and DAC B.

The current source $I_{LEAKAGE}$ is composed of surface and junction leakages and, as with most semiconductor devices, approximately doubles every 10°C. The resistor R_O as shown in Figure 2 is the equivalent output resistance of the device which varies with input code (excluding all 0's code) from 0.8R to 2R. R is typically 11kΩ. C_{OUT} is the capacitance due to the N-channel switches and varies from about 50pF to 120pF depending upon the digital input. g(V_{REF} A, N) is the Thevenin equivalent voltage generator due to the reference input voltage V_{REF} A and the transfer function of the R-2R ladder.

For further information on CMOS multiplying D/A converters refer to "CMOS DAC Application Guide, 2ND Edition" available from Analog Devices, Publication Number G872a–15–4/86.

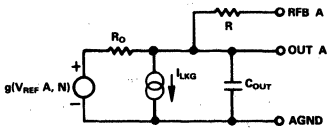

Figure 2. Equivalent Analog Output Circuit of DAC A

CIRCUIT INFORMATION – DIGITAL SECTION

The input buffers are simple CMOS level-shifters designed such that when the AD7628 is operated with V_{DD} from 10.8V to 15.75V, the buffer converts TTL input levels (2.4V and 0.8V) into CMOS logic levels. When V_{IN} is in the region of 1.0 volt to 2.0 volts the input buffers operate in their linear region and pass a quiescent current, see Figure 3. To minimize power supply currents it is recommended that the digital input voltages be as close to the supply rails (V_{DD} and DGND) as is practically possible.

The AD7628 may be operated with any supply voltage in the range $10.8 \leq V_{DD} \leq 15.75$ volts.

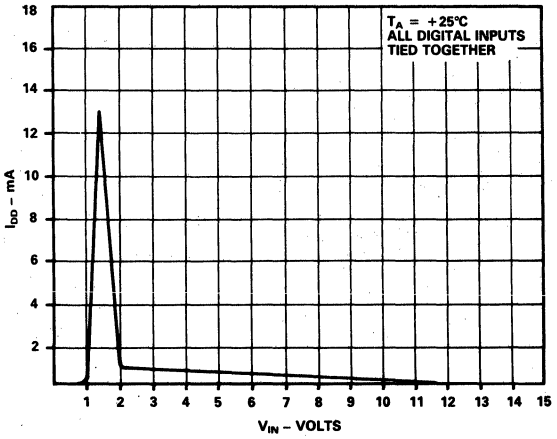

Figure 3. Typical Plot of Supply Current, I_{DD} vs. Logic Input Voltage V_{IN} for V_{DD} = +15V.

5 V/3.3 V Quad and Octal 10-Bit DACs

AD7804/AD7808

FEATURES

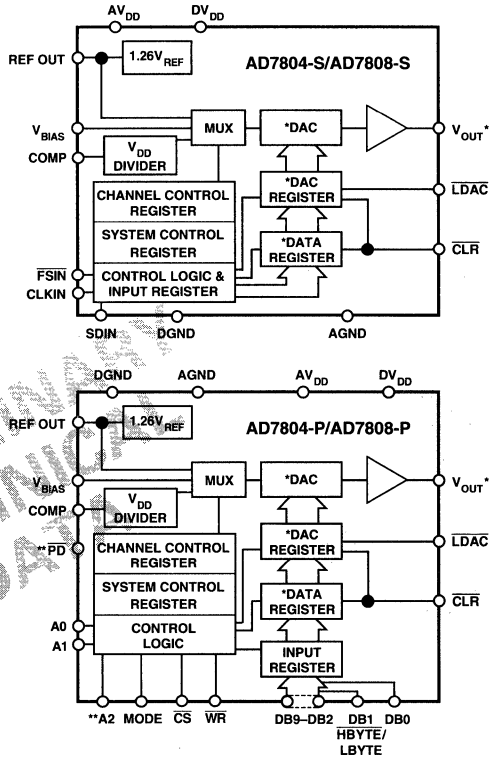
Four/Eight 10-Bit DACs in One Package
Serial and Parallel Loading Facilities Available
- **AD7808-S Octal 10-Bit Serial Loading**
- **AD7808-P Octal 10-Bit Parallel Loading**
- **AD7804-S Quad 10-Bit Serial Loading**
- **AD7804-P Quad 10-Bit Parallel Loading**

3.3 V and 5 V Operation
Low Power All CMOS Construction
10-Bit Resolution, ±1 LSB DNL, ±1 LSB INL
Four/Eight Output Amplifiers
Double Buffered DAC Registers
Power-Down Mode
Low Cost

APPLICATIONS

Optical Disk Drives
Automatic Test Equipment
Instrumentation Systems
Communication Systems
Process Control
Voltage Set Point Control
Trim Potentiometer Replacement
Automatic Calibration

FUNCTIONAL BLOCK DIAGRAMS



* ONLY ONE DAC STRUCTURE SHOWN FOR CLARITY
** PINS ON THE AD7808-P ONLY

GENERAL DESCRIPTION

The AD7804/AD7808 are quad and octal 10-bit digital-to-analog converters, with serial or parallel data load facilities depending on the version used. These parts operate from a +5 V or +3.3 V (±10%) power supply and incorporate an on-board reference. These DACs provide output signals in the form of $V_{BIAS} \pm V_{SWING}$ that swing rail to rail.

On-chip control registers include a system control register and a channel control register. The system control register has control over all DACs in the package. Its controls include power down, input coding select, clearing of all DACs and the facility to put all DACs into standby. The channel control register, allows individual control over all DACs and its contents allow individual DACs to be cleared, put into standby and reference selection for the relevant DAC. The complete transfer function of each individual DAC can be shifted around the V_{BIAS} point using an on-chip 8-bit Sub DAC. All DACs contain double buffered data inputs, which allow all analog outputs to be simultaneously updated using the asynchronous $\overline{LDAC}$ input.

PRODUCT HIGHLIGHTS

1. The AD7804/AD7808 are complete voltage output 10-bit quad and octal DACs capable of operating from 5 V and 3.3 V supplies with on-board reference.
2. CMOS construction ensures very low power dissipation, the part dissipating 5 mW/DAC typically in normal operation.
3. The AD7804-S and AD7808-S have a fast versatile serial interface while the AD7804-P and AD7808-P offer a fast parallel interface. Both interfaces are compatible with all modern microprocessors and microcomputers, and the output voltage settles to ±1/2 LSB within 4 µs.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7804/AD7808—SPECIFICATIONS (V_{DD} as below; AGND = DGND = 0 V; V_{BIAS} = REF OUT; C_L = 100 pF; R_L = 2 kΩ. All specifications T_{MIN} to T_{MAX} unless otherwise noted.)

Parameter	3.3 V ± 10% Version	5 V ± 10% Version	Units	Comments

PIN DESCRIPTION (AD7804-S and AD7808-S)

Mnemonic	Description
AV_{DD}	Analog Power Supply. +5 V or +3 V.
DV_{DD}	Digital Power Supply.
AGND	Ground reference point for analog circuitry.
DGND	Ground reference point for digital circuitry.
V_{BIAS}	This is an external reference input for the DAC. When this reference is selected for the DAC in the control register, the analog output from the selected DAC swings around this point.
REFOUT	Reference Output; this is a bandgap reference and is typically 1.26 V.
CLKIN	Clock Input. Data is clocked into the input shift register on the falling edges of CLKIN.
$\overline{FSIN}$	Level-triggered control input (active low). This is the frame synchronization signal for the input data. When $\overline{FSIN}$ goes low, it enables the input shift register and data is transferred on the falling edges of CLKIN.
SDIN	Serial Data Input. These devices accept a 16-bit word. The first 2 bits (DB15 and DB14) are used to select either writing to the DACs data registers or to the control registers. If the DAC data register is selected, DB13 is used to select either the Main DAC or the Sub DAC, DB12 to DB10 provide the DAC address and DB9 to DB0 contain the 10-bit data. If control registers are selected by the 2 MSBs, then remaining bits are defined in the section Serial Interface.
$\overline{LDAC}$	Asynchronous $\overline{LDAC}$ Input. When this digital input is taken low, all DAC registers are simultaneously updated with the contents of the DAC data registers.
$\overline{CLR}$	Asynchronous $\overline{CLR}$ Input. When this input is taken low, all DAC register outputs are cleared.
$\overline{COMP}$	Compensation Pin. This is a compensation pin for the internal $V_{DD}/2$ reference and should be decoupled with a 0.1 µF capacitor to analog ground.
V_{OUTA}–V_{OUTD}	Analog output voltages from the DACs.
V_{OUTE}–V_{OUTH}	Analog output voltages from the DACs.

ABSOLUTE MAXIMUM RATINGS[1]

PQFP Package, Power Dissipation ..... 500 mW
θ_{JA} Thermal Impedance .....95°C/W
Lead Temperature, Soldering
  Vapor Phase (60 sec) .....+215°C
  Infrared (15 sec) .....+220°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Transient currents of up to 100 mA will not cause SCR latchup.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7804/AD7808 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN DESCRIPTION (AD7804-P and AD7808-P)

Mnemonic	Description
AV_{DD}	Analog Power Supply. +5 V or +3.3 V.
DV_{DD}	Digital Power Supply.
AGND	Ground reference point for analog circuitry.
DGND	Ground reference point for digital circuitry.
V_{BIAS}	This is the midpoint for the DAC outputs. The analog output from the DACs swings around this point.
REFOUT	Reference Output; this is a bandgap reference and is typically 1.23 V.
DB9–DB2	Data Inputs. DB9 to DB2 are the 8 MSBs of the data word. DB9 and DB8 function also as the 2 LSBs of the 10-bit word when BYTE loading structure is used.
DB0	Data Input. Functions as the LSB when in the 10-bit parallel mode.
DB1/($\overline{\text{HBYTE}}$/LBYTE)	Data Input in 10-bit parallel mode. Functions as a high byte and low byte enable when BYTE loading structure is selected.
A0, A1, A2	DAC Address Inputs. These digital inputs are used in conjunction with $\overline{CS}$ and $\overline{WR}$ to determine which DAC channel control register or DAC data register is loaded from the input register.
$\overline{CS}$	Chip Select. Active low logic input.
$\overline{WR}$	Write Input $\overline{WR}$ is an active low logic input which is used in conjunction with $\overline{CS}$ and the address pins to write data to the relevant registers.
$\overline{LDAC}$	Asynchronous $\overline{LDAC}$ Input. When this digital input is taken low, all DAC registers are simultaneously updated with the contents of the DAC data registers.
$\overline{CLR}$	Asynchronous $\overline{CLR}$ Input. When this input is taken low, all Main DAC outputs are cleared either to V_{BIAS} or to $V_{BIAS}/16$ volts. This input does not affect the operation of the Sub DAC.
$\overline{COMP}$	Compensation Pin. This is a compensation pin for the internal $V_{DD}/2$ reference and should be decoupled with a 0.1 μF capacitor to analog ground.
Mode	Logic Input. Logic enables writing to the DAC input register, a logic 1 enables writing to the selected DACs control register.
V_{OUTA}–V_{OUTD}	Analog output voltages from the DACs.
V_{OUTE}–V_{OUTH}	Analog output voltages from the DACs.

INTERFACE SECTION (SERIAL)

The AD7804-S and AD7808-S are serial input devices. Three lines control the serial interface, $\overline{FSIN}$, CLKIN and SDIN. The timing diagram is shown in Figure 1.

When the $\overline{FSIN}$ input goes low, data appearing on the SDIN line is clocked into the input register on each falling edge of CLKIN. When sixteen bits have been received, input register loading is automatically disabled until the next falling edge of $\overline{FSIN}$ is detected. Table I shows the loading sequence for both the AD7804-S and the AD7808-S system control register, Table II shows the sequence for the channel control register and Table III the sequence for loading data to the DAC data registers. Figure 3 shows the internal registers associated with the AD7804-S and AD7808-S serial interface DACs. Only one DAC structure is shown for clarity.

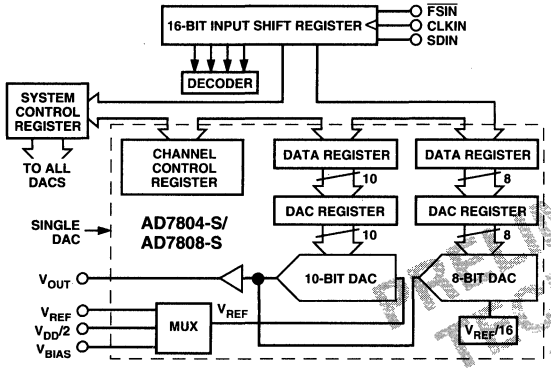

Figure 3. AD7804-S and AD7808-S Internal Registers

DB15 and DB14 (MD1 and MD0) determine whether a write cycle accesses the control registers or the DAC data registers. When the system control register is selected by writing zeros to the modes bits MD1 and MD0, the address bits are ignored as the system control register controls all DACs in the package. When MD1 = 0 and MD0 = 1, writing is to the channel control register. Only the DAC selected by the address bits will be affected by writing to this register. Each individual DAC has a channel control register.

The DACs data registers are addressed by writing a one to both MD1 and MD0 (DB15 and DB14 of the input word). DB13 determines whether writing is to the Main DAC data register or to the Sub DAC data register. The Main DAC is 10 bits wide and the Sub DAC is 8 bits wide. Thus when writing to the Sub DAC, DB9 and DB8 become don't cares. The Sub DAC is used the shift the complete transfer function of the Main DAC around its V_{BIAS} point. The Sub DAC has 1/4 LSB resolution and will enable the transfer function to be shifted by $\pm V_{BIAS}/16$.

When the $\overline{LDAC}$ line goes low, all DAC registers in the device are simultaneously loaded with the contents of their respective DAC data registers, and the outputs change accordingly.

Bringing the $\overline{CLR}$ line low resets the DAC data and DAC registers. This hardware clear only effects the Main DAC, the Sub DAC is not effected by issuing a hardware clear to the part. This operation sets the analog output of the Main DAC to $V_{BIAS}/16$ volts when offset binary coding is selected and the output is set to V_{BIAS} when twos complement coding is used.

Table I. AD7804-S/AD7808-S System Control Register Loading Sequence

INPUT/CONTROL REGISTERS

Two mode bits (MD1 and MD0), which are the two MSBs of the serial word written to the AD7804-S or the AD7808-S, are used to determine whether writing is to the DAC registers or the control registers for these parts. These parts contain a system control register for controlling the operation of all DACs in the package as well as a channel control register for controlling the operation of each individual DAC. All registers are write-only registers. The following table shows how to access these registers.

Table IV. Register Selection

MD1	MD0	Function
0	0	Write Enable to System Control Register
0	1	Write Enable to Channel Control Register
1	1	Write Enable to DAC Data Registers

Figures 1–3 show the contents of the above registers.

DAC SELECTION (A2, A1, A0)

Bits A2, A1 and A0 in the input register are used to address a specific DAC. The following tables show how the DACs are selected.

Table V. AD7808-S DAC Selection

A2	A1	A0	Function
0	0	0	DAC A Selected
0	0	1	DAC B Selected
0	1	0	DAC C Selected
0	1	1	DAC D Selected
1	0	0	DAC E Selected
1	0	1	DAC F Selected
1	1	0	DAC G Selected
1	1	1	DAC H Selected

Table VI. AD7804-S DAC Selection

A2	A1	A0	Function
X	0	0	DAC A Selected
X	0	1	DAC B Selected
X	1	0	DAC C Selected
X	1	1	DAC D Selected

X = Don't Care.

SYSTEM CONTROL REGISTER (MD1 = 0, MD0 = 0)

This register has control over all DACs in the package. The control bits include power down (PD), DAC input coding select (BIN/$\overline{\text{COMP}}$), global standby ($\overline{\text{SSTBY}}$) and a global clear of all Main DACs ($\overline{\text{SCLRM}}$) and a global clear of all Sub DACs ($\overline{\text{SCLRS}}$). The function of these bits is as follows.

POWER DOWN (PD)

This bit in the control register is used to shut down the complete device. With a 1 in this position, the reference and all DACs are put into low power mode. Writing a 0 to this bit puts the part in the normal operating mode. When in power-down mode the contents of all registers are retained and are valid when the device is taken out of standby.

CODING (BIN/$\overline{\text{COMP}}$)

This bit in the global control register allows the user to select one of two input coding schemes. The available schemes are twos complement coding and offset binary coding. All DACs will be configured with the same input coding scheme. Writing a 0 to the control register selects twos complement coding, while writing a 1 to this bit in the control register selects offset binary coding.

With twos complement coding selected, the output voltage from the Main DAC can be calculated as follows:

$$V_{OUT} = V_{BIAS} + 1.875 \times V_{BIAS} \times NA/1024$$

Where NA is the decimal equivalent of the twos complement input code. NA ranges from –512 to +511. See Table IV for V_{BIAS} input.

With offset binary coding selected the output voltage from the Main DAC can be calculated as follows:

$$V_{OUT} = V_{BIAS} + 1.875 \times V_{BIAS} \times ((NA - 512)/1024)$$

Where NA is the decimal equivalent of the offset binary input code. NA ranges from 0 to 1023. See Table IV for V_{BIAS} input.

SYSTEM STANDBY ($\overline{\text{SSTBY}}$)
This bit allows all the DACs in the package to be put into low power mode simultaneously. Writing a 0 to the $\overline{\text{SSTBY}}$ bit in the system control register puts all DACs into standby mode. The following changes take place on writing a 0 to this bit. All linear circuitry is switched off . The V_{OUT} from all DACs is connected through a high impedance to ground. The DACs come out of power-down mode when a 1 is written to the $\overline{\text{SSTBY}}$ bit. The contents of other locations in the control register are retained when the device is placed in power-down mode and are valid when normal operation is restored.

SYSTEM SOFTWARE CLEAR FUNCTIONS ($\overline{\text{SCLRM}}$, $\overline{\text{SCLRS}}$)
This function allows the user to clear the contents of all the DAC registers in software. There are two bits available, one to clear all Main DACs and the second to clear all Sub DACs. The output of the Main DAC can be cleared to one of two places depending on the input coding used. Input coding is also programmable through the system control register. If twos complement coding is selected then issuing a software clear will reset the output of the Main DAC to mid-scale (V_{BIAS}). If offset binary coding is selected the output will be reset to $V_{BIAS}/16$ following the execution of a software clear. The Sub DAC will be cleared to midscale regardless of the input coding selected. Writing a zero to the $\overline{\text{SCLRM}}$ or $\overline{\text{SCLRS}}$ bit in the control register clears the DACs outputs. A 1 in these bit positions puts the DAC in normal operating mode.

CHANNEL CONTROL REGISTER (MD1 = 1, MD0 = 1)
This register allows the user to have control over individual DACs in the package. The control bits in this register include standby ($\overline{\text{STBY}}$), individual DAC clear ($\overline{\text{CLR}}$) and multiplexer output selection (MX1 and MX0). The function of these bits is as follows.

STANDBY ($\overline{\text{STBY}}$)
This bit allows the selected DAC in the package to be put into low power mode. Writing a 0 to the $\overline{\text{STBY}}$ bit in the individual control register puts the selected DAC into standby mode. The following changes take place on writing a zero to this bit. All linear circuitry is switched off. The V_{OUT} from the DAC is connected through a high impedance to ground. The DAC is returned to normal operation by writing a 1 to the $\overline{\text{STBY}}$ bit. The contents of other locations in the control register are retained when the device is placed in power-down mode and are valid when normal operation is restored.

SOFTWARE CLEAR FUNCTION ($\overline{\text{CLR}}$)
This function allows the user to clear the contents of the selected DAC latch in software. This software clear, clears only the Main DAC contents of the Sub DAC. DAC register is unaffected by a $\overline{\text{CLR}}$ operation. The output of the Main DAC can be cleared to one of two places depending on the input coding used. Input coding is also programmable through the global control register. If twos complement coding is selected, then issuing a software clear will reset the output of the Main DAC to midscale (V_{BIAS}). If offset binary coding is selected, the output will be reset to $V_{BIAS}/16$ following the execution of a software clear. Writing a 0 to the $\overline{\text{CLR}}$ bit in the control register clears the DACs output. A 1 in the $\overline{\text{CLR}}$ bit position puts the DAC in normal operating mode.

MULTIPLEXER SELECTION (MX1, MX0)
These two bits are used to select the reference input for the selected DAC. The following table shows the options available.

Table VII. Multiplexer Output Selection

MX1	MX0	V_{BIAS}
0	1	INTERNAL V_{REF}
1	1	$V_{DD}/2$
1	0	EXT V_{BIAS}

SUB DAC DATA REGISTER
Figure 3 shows the loading sequence for writing to the data registers of the DACs. DB13 determines whether writing is to the Main or Sub DACs data register. A one in this position selects the addressed Sub DACs data register. The Sub DAC is eight-bits wide and thus DB9 and DB8 are don't cares when writing to the Sub DAC. This Sub DAC allows the complete transfer function of each individual DAC to be shifted around the V_{BIAS} point. This is achieved by using a Sub DAC whose output is either added or subtracted to the output of the Main DAC. This Sub DAC has a span of $\pm V_{DAC}/16$ with 1/4-bit resolution. An 8-bit DAC is used to implement this function. The output of this Sub DAC is guaranteed monotonic. The coding scheme for the Sub DAC is programmed through the control register. With offset binary coding the transfer function for the Sub DAC is

$$V_{BIAS}/16 \times (2 \times NA/256-1)$$

where NA is the digital code written to the Sub DAC and varies from 0 to 255. See Table IV for V_{BIAS} input.

With twos complement coding the transfer function for the Sub DAC is:

$$V_{BIAS}/8 \times (NB/256)$$

where NB is the digital code written to the Sub DAC and varies from –128 to 127. See Table IV for V_{BIAS} input.

The DAC register for the relevant Sub DAC is selected by writing 0, 1 to the mode bits MD1 and MD0.

CONTROL REGISTER (PARALLEL VERSION)

Access to the control register of the AD7804-P and the AD7808-P is achieved by taking the mode pin to a logic high. The control register of these DACs is eight bits wide and is configured as in Tables V and VI. There are two control registers associated with the part. System control register which looks after the input coding, data format, power down, global clear and global standby. The channel control register contains bits that effect the operation of the selected DAC. The external address bits are used to select the DACs. When mode is high, the two mode bits select which of the control registers is being addressed.

Table VIII. AD7804-P and AD7808-P System Control Register Configuration

DB9									DB0
0	X	$\overline{SCLRS}$	$\overline{SCLRM}$	$\overline{SSTBY}$	PD	BIN/$\overline{COMP}$	$\overline{10}$/8	X	MD0 = 0

Table IX. AD7804-P and AD7808-P Channel Control Register Configuration

DB9									DB0
X	MX1	MX0	$\overline{CLR}$	$\overline{STBY}$	X	X	$\overline{MAIN}$/SUB	X	MD0 = 1

Each DAC has a separate channel control register. The following is a brief discussion on each bit in these registers.

SYSTEM OR CHANNEL CONTROL REGISTER SELECTION

MD0

0 This enables writing to the system control register. The contents of this are shown in Table VIII. Mode must be low to access this control register.

1 This enables writing to the channel control register. The contents of this are shown in Table IX. Mode must also be low to access this control register.

DATA FORMAT

$\overline{10}$/8

0 10-Bit Parallel Loading Structure (Default on Power-Up).

1 Byte Loading Structure (8 + 2 Loading Left Justified Data).

INPUT CODING

BIN/$\overline{COMP}$

0 Twos Complement Coding.

1 Offset Binary Coding (Default on Power-Up).

POWER DOWN

PD

0 Normal Operation.

1 Complete Power Down of Device (Default on Power-Up).

SYSTEM STANDBY

$\overline{SSTBY}$

0 All DACs in the Package Put in Standby Mode.

1 Normal Operation (Default on Power-Up).

SYSTEM CLEAR

$\overline{SCLRM}$ & $\overline{SCLRS}$

0 All DACs in the package are cleared to a known state depending on the coding scheme selected. The $\overline{SCLRM}$ bit clears the Main DACs while the $\overline{SCLRS}$ bit clears the Sub DACs. The Sub DAC is always cleared to mid-scale regardless of the coding. The Main DAC is cleared to different levels depending on the coding scheme. With offset binary coding the output is cleared to $V_{BIAS}/16$. With twos complement coding the output is cleared to V_{BIAS}.

1 Normal Operation (Default on Power-Up).

MAIN DAC OR SUB DAC SELECTION

MAIN/$\overline{SUB}$

0 When Mode is taken low, writing to the AD7804/AD7808 loads data to the input register of the selected Sub DAC.

1 Writing to the DAC with MODE low loads data to the input register of the selected Main DAC (Default Condition on Power-Up).

LC²MOS
Complete, Dual 12-Bit MDACs
AD7837/AD7847

FEATURES
Two 12-Bit MDACS with Output Amplifiers
4-Quadrant Multiplication
Space-Saving 0.3", 24-Pin DIP and 24-Terminal SOIC Package
Parallel Loading Structure: AD7847
(8 + 4) Loading Structure: AD7837

APPLICATIONS
Automatic Test Equipment
Function Generation
Waveform Reconstruction
Programmable Power Supplies
Synchro Applications

GENERAL DESCRIPTION

The AD7837/AD7847 is a complete, dual, 12-bit multiplying digital-to-analog converter with output amplifiers on a monolithic CMOS chip. No external user trims are required to achieve full specified performance.

Both parts are microprocessor compatible, with high speed data latches and interface logic. The AD7847 accepts 12-bit parallel data which is loaded into the respective DAC latch using the $\overline{WR}$ input and a separate Chip Select input for each DAC. The AD7837 has a double-buffered 8-bit bus interface structure with data loaded to the respective input latch in two write operations. An asynchronous $\overline{LDAC}$ signal on the AD7837 updates the DAC latches and analog outputs.

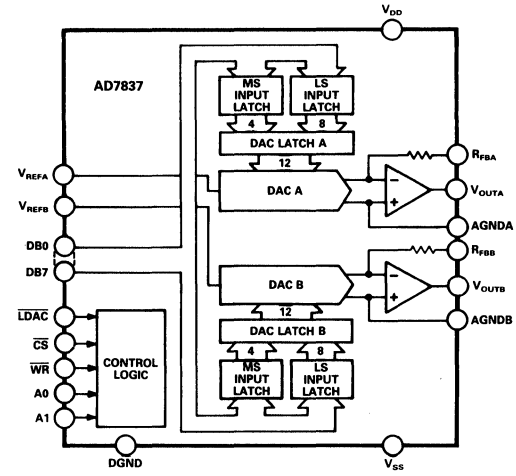
The output amplifiers are capable of developing ±10 V across a 2 kΩ load. They are internally compensated with low input offset voltage due to laser trimming at wafer level.

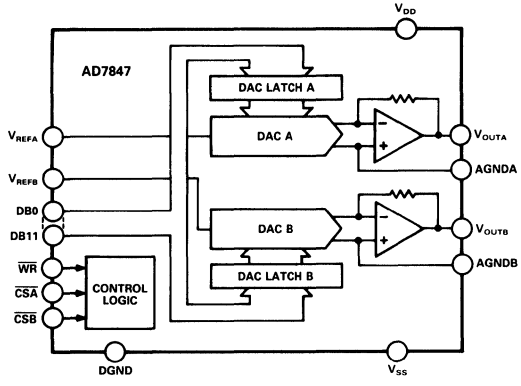
The amplifier feedback resistors are internally connected to V_{OUT} on the AD7847.

The AD7837/AD7847 is fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic.

A novel low leakage configuration (U.S. Patent No. 4,590,456) ensures low offset errors over the specified temperature range.

FUNCTIONAL BLOCK DIAGRAMS





PRODUCT HIGHLIGHTS

1. The AD7837/AD7847 is a dual, 12-bit, voltage-out MDAC on a single chip. This single chip design offers considerable space saving and increased reliability over multichip designs.
2. The AD7837 and the AD7847 provide a fast versatile interface to 8-bit or 16-bit data bus structures.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Derates above +75°C by ..... 10 mW/°C

NOTES
[1]If V_{SS} is open circuited with V_{DD} and either AGND applied, the V_{SS} pin will float positive, exceeding the Absolute Maximum Ratings. If this possibility exists, a Schottky diode connected between V_{SS} and AGND (cathode to AGND) ensures the Maximum Ratings will be observed.
[2]The outputs may be shorted to voltages in this range provided the power dissipation of the package is not exceeded.
[3]AD7837 only.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

ORDERING GUIDE

NOTES
[1]To order MIL-STD-883, Class B processed parts, add /883B to part number.
[2]N = Plastic DIP; Q = Cerdip; R = SOIC. For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

TERMINOLOGY

Relative Accuray (Linearity)
Relative accuracy, or endpoint linearity, is a measure of the maximum deviation of the DAC transfer function from a straight line passing through the endpoints. It is measured after allowing for zero and full-scale errors and is expressed in LSBs or as a percentage of full-scale reading.

Differential Nonlinearity
Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB or less over the operating temperature range ensures monotonicity.

Zero Code Offset Error
Zero code offset error is the error in output voltage from V_{OUTA} or V_{OUTB} with all 0s loaded into the DAC latches. It is due to a combination of the DAC leakage current and offset errors in the output amplifier.

Gain Error
Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded. It does not include offset error.

Total Harmonic Distortion
This is the ratio of the root-mean-square (rms) sum of the harmonics to the fundamental, expressed in dBs.

Multiplying Feedthrough Error
This is an ac error due to capacitive feedthrough from the V_{REF} input to V_{OUT} of the same DAC when the DAC latch is loaded with all 0s.

Channel-to-Channel Isolation
This is an ac error due to capacitive feedthrough from the V_{REF} input on one DAC to V_{OUT} on the other DAC. It is measured with the DAC latches loaded with all 0s.

Digital Feedthrough
Digital feedthrough is the glitch impulse injected from the digital inputs to the analog output when the data inputs change state, but the data in the DAC latches is not changed.

For the AD7837, it is measured with $\overline{LDAC}$ held high. For the AD7847, it is measured with $\overline{CSA}$ and $\overline{CSB}$ held high.

Digital Crosstalk
Digital crosstalk is the glitch impulse transferred to the output of one converter due to a change in digital code on the DAC latch of the other converter. It is specified in nV secs.

Digital-to-Analog Glitch Impulse
This is the voltage spike that appears at the output of the DAC when the digital code changes, before the output settles to its final value. The energy in the glitch is specified in nV secs and is measured for a 1 LSB change around the major carry transition (0111 1111 1111 to 1000 0000 0000).

Unity Gain Small Signal Bandwidth
This is the frequency at which the small signal voltage output from the output amplifier is 3 dB below its dc level. It is measured with the DAC latch loaded with all 1s.

Full Power Bandwidth
This is the maximum frequency for which a sinusoidal input signal will produce full output at rated load with a distortion less than 3%. It is measured with the DAC latch loaded with all 1s.

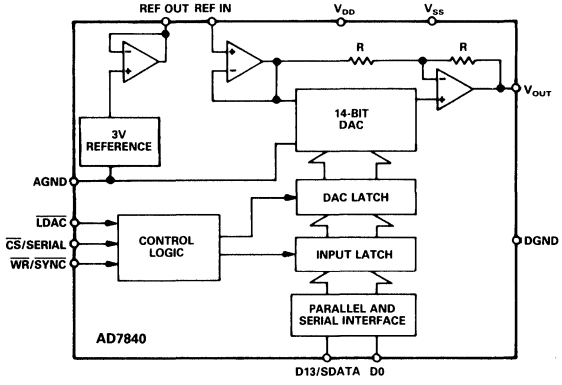
FEATURES

Complete 14-Bit Voltage Output DAC
Parallel and Serial Interface Capability
80dB Signal-to-Noise Ratio
Interfaces to High Speed DSP Processors
e.g., ADSP-2100, TMS32010, TMS32020
45ns min $\overline{WR}$ Pulse Width
Low Power – 70mW typ.
Operates from ±5V Supplies

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7840 is a fast, complete 14-bit voltage output D/A converter. It consists of a 14-bit DAC, 3V buried Zener reference, DAC output amplifier and high speed control logic.

The part features double-buffered interface logic with a 14-bit input latch and 14-bit DAC latch. Data is loaded to the input latch in either of two modes, parallel or serial. This data is then transferred to the DAC latch under control of an asynchronous $\overline{LDAC}$ signal. A fast data setup time of 21ns allows direct parallel interfacing to digital signal processors and high speed 16-bit microprocessors. In the serial mode, the maximum serial data clock rate can be as high as 6MHz.

The analog output from the AD7840 provides a bipolar output range of ±3V. The AD7840 is fully specified for dynamic performance parameters such as signal-to-noise ratio and harmonic distortion as well as for traditional dc specifications. Full power output signals up to 20kHz can be created.

The AD7840 is fabricated in linear compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin plastic and hermetic dual-in-line package (DIP) and is also packaged in a 28-terminal plastic leaded chip carrier (PLCC).

NOTES
[1]Temperature ranges are as follows: J, K Versions, 0 to +70°C; A, B Versions, −25°C to +85°C; S Version, −55°C to +125°C.
[2]V_{OUT} (pk-pk)=±3V.
[3]SNR calculation includes distortion and noise components.
[4]Using external sample-and-hold (see Testing the AD7840).
[5]Measured with respect to REF IN and includes bipolar offset error.
[6]For capacitive loads greater than 50pF, a series resistor is required (see Internal Reference section).
[7]Sample tested @ +25°C to ensure compliance.
Specifications subject to change without notice.

TIMING CHARACTERISTICS[1, 2] (V_{DD} = +5V ±5%, V_{SS} = −5V ±5%, AGND = DGND = 0V.)

Parameter	Limit at T_{min}, T_{max} (J, K, A, B Versions)	Limit at T_{min}, T_{max} (S Version)	Units	Conditions/Comments
t_1	0	0	ns min	$\overline{CS}$ to $\overline{WR}$ Setup Time
t_2	0	0	ns min	$\overline{CS}$ to $\overline{WR}$ Hold Time
t_3	**45**	**50**	ns min	$\overline{WR}$ Pulse Width
t_4	**21**	**28**	ns min	Data Valid to $\overline{WR}$ Setup Time
t_5	**10**	**15**	ns min	Data Valid to $\overline{WR}$ Hold Time
t_6	40	40	ns min	$\overline{LDAC}$ Pulse Width
t_7	50	50	ns min	$\overline{SYNC}$ to SCLK Falling Edge
t_8[3]	150	200	ns min	SCLK Cycle Time
t_9	30	40	ns min	Data Valid to SCLK Setup Time
t_{10}	75	100	ns min	Data Valid to SCLK Hold Time
t_{11}	75	100	ns min	$\overline{SYNC}$ to SCLK Hold Time

NOTE
[1]Timing specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr= tf= 5ns (10% to 90% of 5V) and timed from a voltage level of 1.6V.
[2]See Figures 6 and 8.
[3]SCLK mark/space ratio is 40/60 to 60/40.
Specifications subject to change without notice.

Derates above +75°C by . . . . . 10mW/°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN FUNCTION DESCRIPTION

DIP Pin No.	Pin Mnemonic	Function
1	$\overline{CS}$/SERIAL	Chip Select/Serial Input. When driven with normal logic levels, it is an active low logic input which is used in conjunction with $\overline{WR}$ to load parallel data to the input latch. For applications where $\overline{CS}$ is permanently low, an R, C is required for correct power-up (see $\overline{LDAC}$ input). If this input is tied to V_{SS}, it defines the AD7840 for serial mode operation.
2	$\overline{WR}$/$\overline{SYNC}$	Write/Frame Synchronization Input. In the parallel data mode, it is used in conjunction with $\overline{CS}$ to load parallel data. In the serial mode of operation, this pin functions as a Frame Synchronization pulse with serial data expected after the falling edge of this signal.
3	D13/SDATA	Data Bit 13(MSB)/Serial Data. When parallel data is selected, this pin is the D13 input. In serial mode, SDATA is the serial data input which is used in conjunction with $\overline{SYNC}$ and SCLK to transfer serial data to the AD7840 input latch.
4	D12/SCLK	Data Bit 12/Serial Clock. When parallel data is selected, this pin is the D12 input. In the serial mode, it is the serial clock input. Serial data bits are latched on the falling edge of SCLK when $\overline{SYNC}$ is low.
5	D11/FORMAT	Data Bit 11/Data Format. When parallel data is selected, this pin is the D11 input. In serial mode, a logic 1 on this input indicates that the MSB is the first valid bit in the serial data stream. A logic 0 indicates that the LSB is the first valid bit (see Table I).
6	D10/JUSTIFY	Data Bit 10/Data Justification. When parallel data is selected, this pin is the D10 input. In serial mode, this input controls the serial data justification (see Table I).
7–11	D9–D5	Data Bit 9 to Data Bit 5. Parallel data inputs.
12	DGND	Digital Ground. Ground reference for digital circuitry.
13–16	D4–D1	Data Bit 4 to Data Bit 1. Parallel data inputs.
17	D0	Data Bit 0 (LSB). Parallel data input.
18	V_{DD}	Positive Supply, +5V± 5%.
19	AGND	Analog Ground. Ground reference for DAC, reference and output buffer amplifier.
20	V_{OUT}	Analog Output Voltage. This is the buffer amplifier output voltage. Bipolar output range (±3V with REF IN = +3V).
21	V_{SS}	Negative Supply Voltage, −5V ±5%.
22	REF OUT	Voltage Reference Output. The internal 3V analog reference is provided at this pin. To operate the AD7840 with internal reference, REF OUT should be connected to REF IN. The external load capability of the reference is 500μA.
23	REF IN	Voltage Reference Input. The reference voltage for the DAC is applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7840 is 3V.
24	$\overline{LDAC}$	Load DAC. Logic input. A new word is loaded into the DAC latch from the input latch on the falling edge of this signal (see Interface Logic Information section). The AD7840 should be powered-up with $\overline{LDAC}$ high. For applications where $\overline{LDAC}$ is permanently low, an R, C is required for correct power-up (see Figure 19).

ANALOG DEVICES

LC²MOS Complete 12-Bit Multiplying DAC

AD7845

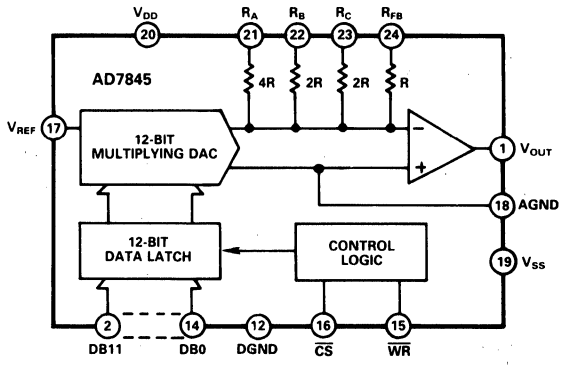
FEATURES

12-Bit CMOS MDAC with Output Amplifier
4-Quadrant Multiplication
Guaranteed Monotonic (T_{MIN} to T_{MAX})
Space-Saving 0.3" DIPs and 24- or 28-Terminal Surface Mount Packages
Application Resistors On Chip for Gain Ranging, etc.
Low Power LC²MOS

APPLICATIONS

Automatic Test Equipment
Digital Attenuators
Programmable Power Supplies
Programmable Gain Amplifiers
Digital-to-4–20 mA Converters

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7845 is the industry's first 4-quadrant multiplying D/A converter with an on-chip amplifier. It is fabricated on the LC²MOS process, which allows precision linear components and digital circuitry to be implemented on the same chip.

The 12 data inputs drive latches which are controlled by standard $\overline{CS}$ and $\overline{WR}$ signals, making microprocessor interfacing simple. For stand-alone operation, the $\overline{CS}$ and $\overline{WR}$ inputs can be tied to ground, making all latches transparent. All digital inputs are TTL and 5 V CMOS compatible.

The output amplifier can supply ±10 V into a 2 kΩ load. It is internally compensated, and its input offset voltage is low due to laser trimming at wafer level. For normal operation, R_{FB} is tied to V_{OUT}, but the user may alternatively choose R_A, R_B or R_C to scale the output voltage range.

PRODUCT HIGHLIGHTS

1. Voltage Output Multiplying DAC
   The AD7845 is the first DAC which has a full 4-quadrant multiplying capability and an output amplifier on chip. All specifications include amplifier performance.
2. Matched Application Resistors
   Three application resistors provide an easy facility for gain ranging, voltage offsetting, etc.
3. Space Saving
   The AD7845 saves space in two ways. The integration of the output amplifier on chip means that chip count is reduced. The part is housed in skinny 24-pin, 0.3" DIP, 28-terminal LCC and PLCC and 24-terminal SOIC packages.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTE
[1]V_{OUT} may be shorted to AGND provided that the power dissipation of the package is not exceeded.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

LEAST SIGNIFICANT BIT

This is the analog weighting of 1 bit of the digital word in a DAC. For the AD7845, 1LSB = $\frac{V_{REF}}{2^{12}}$.

RELATIVE ACCURACY

Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for both endpoints (i.e., offset and gain error are adjusted out) and is normally expressed in least significant bits or as a percentage of full-scale range.

DIFFERENTIAL NONLINEARITY

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of +1 LSB max over the operating temperature range ensures monotonicity.

GAIN ERROR

Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been adjusted out. Gain error is adjustable to zero with an external potentiometer. See Figure 13.

ZERO CODE OFFSET ERROR

This is the error present at the device output with all 0s loaded in the DAC. It is due to the op amp input offset voltage and bias current and the DAC leakage current.

TOTAL HARMONIC DISTORTION

This is the ratio of the root-mean-square (rms) sum of the harmonics to the fundamental, expressed in dBs.

OUTPUT NOISE

This is the noise due to the white noise of the DAC and the input noise of the amplifier.

DIGITAL-TO-ANALOG GLITCH IMPULSE

This is the amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage. The measurement takes place with V_{REF} = AGND.

DIGITAL FEEDTHROUGH

When the DAC is not selected (i.e., $\overline{CS}$ is high) high frequency logic activity on the device digital inputs is capacitively coupled through the device to show up as noise on the V_{OUT} pin. This noise is digital feedthrough.

MULTIPLYING FEEDTHROUGH ERROR

This is ac error due to capacitive feedthrough from the V_{REF} terminal to V_{OUT} when the DAC is loaded with all 0s.

OPEN-LOOP GAIN

Open-loop gain is defined as the ratio of a change of output voltage to the voltage applied at the V_{REF} pin with all 1s loaded in the DAC. It is specified at dc.

UNITY GAIN SMALL SIGNAL BANDWIDTH

This is the frequency at which the magnitude of the small signal voltage gain of the output amplifier is 3 dB below unity. The device is operated as a closed-loop unity gain inverter (i.e., DAC is loaded with all 1s).

OUTPUT RESISTANCE

This is the effective output source resistance.

FULL POWER BANDWIDTH

Full power bandwidth is specified as the maximum frequency, at unity closed-loop gain, for which a sinusoidal input signal will produce full output at rated load without exceeding a distortion level of 3%.

ANALOG DEVICES

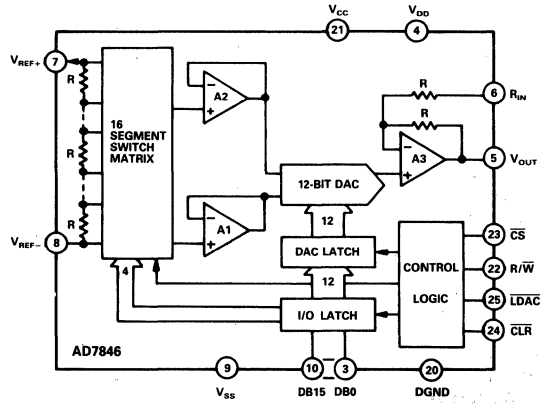
LC²MOS 16-Bit Voltage Output DAC

AD7846

FEATURES

16-Bit Monotonicity over Temperature
±2LSBs Integral Linearity Error
Microprocessor Compatible with Readback Capability
Unipolar or Bipolar Output
Multiplying Capability
Low Power (100mW typical)

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7846 is a 16-bit DAC constructed with Analog Devices' LC²MOS process. It has V_{REF+} and V_{REF-} reference inputs and an on-chip output amplifier. These can be configured to give a unipolar output range (0 to +5V, 0 to +10V) or bipolar output ranges (±5V, ±10V).

The DAC uses a segmented architecture. The 4MSBs in the DAC latch select one of the segments in a 16-resistor string. Both taps of the segment are buffered by amplifiers and fed to a 12-bit DAC, which provides a further 12 bits of resolution. This architecture ensures 16-bit monotonicity. Excellent integral linearity results from tight matching between the input offset voltages of the two buffer amplifiers.

In addition to the excellent accuracy specifications, the AD7846 also offers a comprehensive microprocessor interface. There are 16 data I/O pins, plus control lines ($\overline{CS}$, R/$\overline{W}$, $\overline{LDAC}$ and $\overline{CLR}$). R/$\overline{W}$ and $\overline{CS}$ allow writing to and reading from the I/O latch. This is the readback function which is useful in ATE applications. $\overline{LDAC}$ allows simultaneous updating of DACs in a multi-DAC system and the $\overline{CLR}$ line will reset the contents the DAC latch to 00 . . . 000 or 10 . . . 000 depending on the state of R/$\overline{W}$. This means that the DAC output can be reset to 0V in both the unipolar and bipolar configurations.

The AD7846 is available in 28-pin plastic, ceramic, LCCC and PLCC packages.

PRODUCT HIGHLIGHTS

1. 16-Bit Monotonicity
   The guaranteed 16-bit monotonicity over temperature makes the AD7846 ideal for closed-loop applications.
2. Readback
   The ability to read back the DAC register contents minimizes software routines when the AD7846 is used in ATE systems.
3. Power Dissipation
   Power dissipation of 100mW makes the AD7846 the lowest power, high accuracy DAC on the market.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Timing specifications are sample tested at 25°C to ensure compliance. All input control signals are specified with t_R = t_F = 5 ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]t_6 is measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[3]t_7 is defined as the time required for an output to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

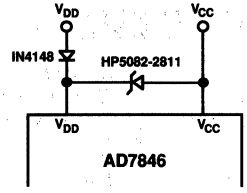
NOTES

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

[2]V_{CC} must not exceed V_{DD} by more than 0.3V. If it is possible for this to happen during power supply sequencing, the following diode protection scheme will ensure protection.



[3]V_{OUT} may be shorted to DGND, V_{DD}, V_{SS}, V_{CC} provided that the power dissipation of the package is not exceeded.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

GENERAL DESCRIPTION

The AD7849 is a 14-bit/16-bit serial input multiplying DAC. The DAC architecture ensures excellent differential linearity performance, and monotonicity is guaranteed to 14 bits for the A grade and to 16 bits for all other grades over the specified temperature ranges.

During power-up and power-down sequences (when the supply voltages are changing), the V_{OUT} pin is clamped to 0 V via a low impedance path. To prevent the output of A3 being shorted to 0 V during this time, transmission gate G1 is also opened. These conditions are maintained until the power supplies stabilize and a valid word is written to the DAC register. At this time, G2 opens and G1 closes. Both transmission gates are also externally controllable via the Reset In ($\overline{\text{RST IN}}$) control input. For instance, if the $\overline{\text{RST IN}}$ input is driven from a battery supervisor chip, then on power-off or during a brown out, the $\overline{\text{RST IN}}$ input will be driven low to open G1 and close G2. The DAC must be reloaded, with $\overline{\text{RST IN}}$ high, to re-enable the output. Conversely, the on-chip voltage detector output ($\overline{\text{RST OUT}}$) is also available to the user to control other parts of the system.

The AD7849 has a versatile serial interface structure and can be controlled over three lines to facilitate opto-isolator applications.

SDOUT is the output of the on-chip shift register and can be used in a daisy-chain fashion to program devices in the multi-channel system. The DCEN (Daisy Chain Enable) input controls this function.

The $\overline{\text{BIN}}$/COMP pin sets the DAC coding; with $\overline{\text{BIN}}$/COMP set to 0, the coding is straight binary; and with it set to 1, the coding is 2s complement. This allows the user to reset the DAC to 0 V in both the unipolar and bipolar output ranges.

In addition, the output loop is closed externally allowing the user to accurately drive remote loads using force and sense techniques.

The part is available in a 20-pin DIP and 20-pin SOIC package.

    Vapor Phase (60 secs) ..... +215°C
    Infrared (15 secs) ..... +220°C

NOTES

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]V_{OUT} may be shorted to DGND, V_{DD}, V_{SS}, provided that the power dissipation of the package is not exceeded.

[3]Transient currents of up to 100 mA will not cause SCR latch-up.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7849 feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

ORDERING GUIDE

Model	Temperature Range	Resolution (Bits)	Bipolar INL (LSBs)	Package Option*
AD7849AN	–40°C to +85°C	14	±2	N-20

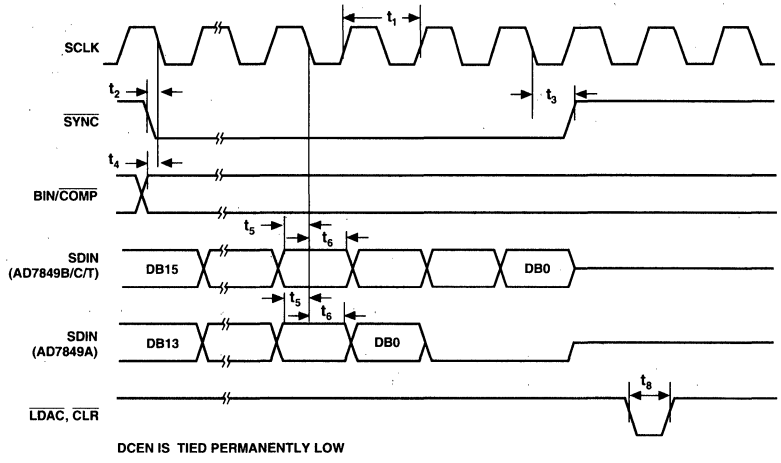

Figure1. Timing Diagram (Stand-Alone Mode)

DIGITAL INTERFACE

The AD7849 contains an input serial to parallel shift register and a DAC latch. A simplified diagram of the input loading circuitry is shown in Figure 2. Serial data on the SDIN input is loaded to the input register under control of DCEN, $\overline{SYNC}$ and, SCLK. When a complete word is held in the shift register, it may then be loaded into the DAC latch under control of $\overline{LDAC}$. Only the data in the DAC latch determines the analog output on the AD7849.

The DCEN (daisy-chain enable) input is used to select either a stand-alone mode or a daisy-chain mode. The loading format is slightly different depending on which mode is selected .

Serial Data Loading Format (Stand-Alone Mode)

With DCEN at logic 0 the stand-alone mode is selected. In this mode a low $\overline{SYNC}$ input provides the frame synchronization signal which tells the AD7849 that valid serial data on the SDIN input will be available for the next 16 falling edges of SCLK. An internal counter/decoder circuit provides a low gating signal so that only 16 data bits are clocked into the input shift register. After 16 SCLK pulses the internal gating signal goes inactive (high) thus locking out any further clock pulses. Therefore either a continuous clock or a burst clock source may be used to clock in the data.

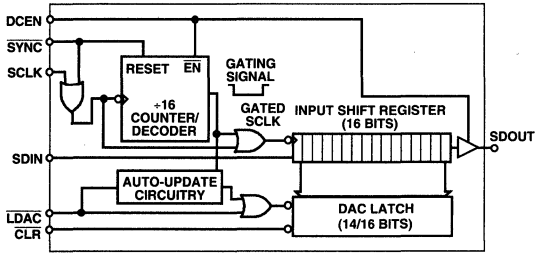

Figure 2. Simplified Loading Structure

The $\overline{SYNC}$ input is taken high after the complete 16-bit word is loaded in.

The AD7849B, AD7849C and AD7849T versions are 16-bit resolution DACs and have a straight 16-bit load format, with the MSB (DB15) being loaded first. The AD7849A is a 14-bit DAC, but the loading structure is still 16-bit. The MSB (DB13) is loaded first and the final two bits of the 16-bit stream must be 0s.

There are two ways in which the DAC latch and hence the analog output may be updated. The status of the $\overline{LDAC}$ input is examined after $\overline{SYNC}$ is taken low. Depending on its status, one of two update modes is selected.

If $\overline{LDAC}$ = 0, then the automatic update mode is selected. In this mode the DAC latch and analog output are updated automatically when the last bit in the serial data stream is clocked in. The update thus takes place on the sixteenth falling SCLK edge.

If $\overline{LDAC}$ = 1, then the automatic update is disabled. The DAC latch update and output update are now separate. The DAC latch is updated on the falling edge of $\overline{LDAC}$. However, the output update is delayed for a further 2 µs by means of an internal track-and-hold amplifier in the output stage. This function results in lower digital-to-analog glitch impulse at the DAC output. Note that the $\overline{LDAC}$ input must be taken back high again before the next data transfer is initiated.

Serial Data Loading Format (Daisy-Chain Mode)
By connecting DCEN high, the daisy-chain mode is enabled. This mode of operation is designed for multi-DAC systems where several AD7849s may be connected in cascade. In this mode, the internal gating circuitry on SCLK is disabled and a serial data output facility is enabled. The internal gating signal is permanently active (low) so that the SCLK signal is continuously applied to the input shift register when $\overline{SYNC}$ is low. The data is clocked into the register on each falling SCLK edge after $\overline{SYNC}$ going low. If more than 16 clock pulses are applied, the data ripples out of the shift register and appears on the SDOUT line. By connecting this line to the SDIN input on the next AD7849 in the chain, a multi-DAC interface may be constructed. Sixteen SCLK pulses are required for each DAC in the system. Therefore, the total number of clock cycles must equal 16 × N where N is the total number of devices in the chain. When the serial transfer to all devices is complete, $\overline{SYNC}$ is taken high. This prevents any further data being clocked into the input register.

A continuous SCLK source may be used if it can be arranged that $\overline{SYNC}$ is held low for the correct number of clock cycles. Alternatively, a burst clock containing the exact number of clock cycles may be used and $\overline{SYNC}$ taken high some time later.

When the transfer to all input registers is complete, a common $\overline{LDAC}$ signal updates all DAC latches with the data in each input register. All analog outputs are therefore updated simultaneously, 2 µs after the falling edge of $\overline{LDAC}$.

Clear Function ($\overline{CLR}$)
The clear function bypasses the input shift register and loads the DAC Latch with all 0s. It is activated by taking $\overline{CLR}$ low. In all ranges except the Offset Binary bipolar range (–5 V to +5 V) the output voltage is reset to 0 V. In the offset binary bipolar range the output is set to V_{REF-}. This clear function is distinct and separate from the automatic power-on reset feature of the device.

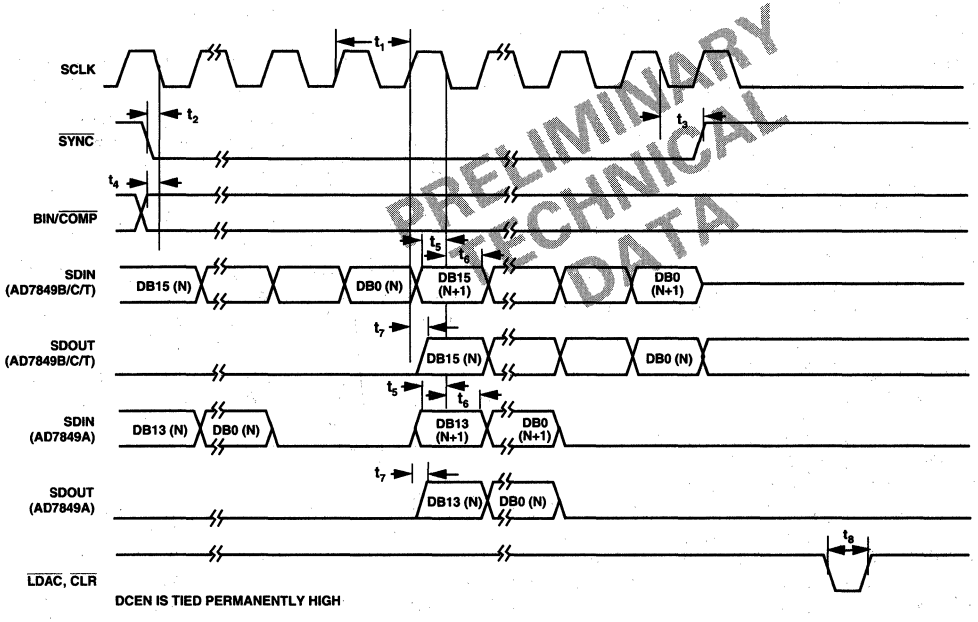

Figure 3. Timing Diagram (Daisy-Chain Mode)

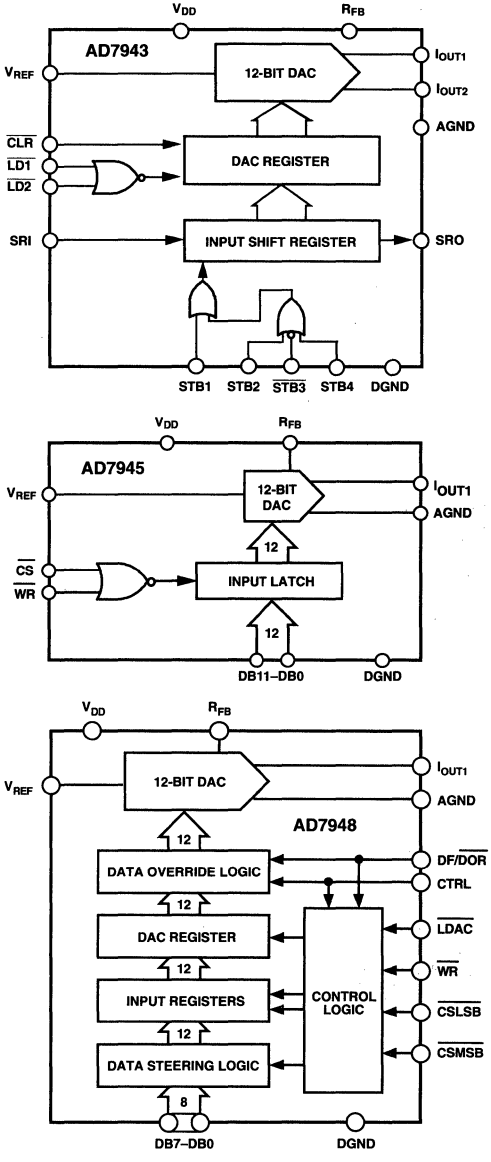
+3.3 V/+5 V Multiplying 12-Bit DACs

AD7943/AD7945/AD7948

FEATURES
12-Bit Multiplying DACs
Guaranteed Specifications with +3.3 V/+5 V Supply
0.5 LSBs INL and DNL
Low Power: 5 μW typ
Fast Interface
40 ns Strobe Pulse Width (AD7943)
40 ns Write Pulse Width (AD7945, AD7948)
Low Glitch: 60 nV-s with Amplifier Connected
Fast Settling: 600 ns to 0.01% with AD843

APPLICATIONS
Battery-Powered Instrumentation
Laptop Computers
Upgrades for All 754x Series DACs (5 V Designs)

FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The AD7943, AD7945 and AD7948 are fast 12-bit multiplying DACs that operate from a single +5 V supply (Normal Mode) and a single +3.3 V to +5 V supply (Biased Mode). The AD7943 has a serial interface, the AD7945 has a 12-bit parallel interface, and the AD7948 has an 8-bit byte interface. They will replace the industry-standard AD7543, AD7545 and AD7548 in many applications, and they offer superior speed and power consumption performance.

The AD7943 is available in 16-pin DIP, 16-pin SOP (Small Outline Package) and 20-pin SSOP (Shrink Small Outline Package).

The AD7945 is available in 20-pin DIP, 20-pin SOP and 20-pin SSOP.

The AD7948 is available in 20-pin DIP, 20-pin SOP and 20-pin SSOP.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

AD7943/AD7945/AD7948–SPECIFICATIONS[1]

NORMAL MODE (AD7943: V_{DD} = +4.5 V to +5.5 V; V_{IOUT1} = V_{IOUT2} = AGND = 0 V; V_{REF} = +10 V; T_A = T_{MIN} to T_{MAX}, unless otherwise noted. AD7945, AD7948: V_{DD} = +4.5 V to +5.5 V; V_{IOUT1} = AGND = 0 V; V_{REF} = +10 V; T_A = T_{MIN} to T_{MAX}, unless otherwise noted.)

Parameter	B Grades[2]	T Grade[2, 3]	Units	Test Conditions/Comments
ACCURACY				
Resolution	12	12	Bits	1 LSB = $V_{REF}/2^{12}$ = 2.44 mV when V_{REF} = 10 V

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Transient currents of up to 100 mA will not cause SCR latch-up.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

TERMINOLOGY

Relative Accuracy
Relative Accuracy or endpoint linearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero error and full-scale error and is normally expressed in Least Significant Bits or as a percentage of full-scale reading.

Differential Nonlinearity
Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of 1 LSB maximum ensures monotonicity.

Gain Error
Gain Error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in Least Significant Bits. Gain error is adjustable to zero with an external potentiometer.

Output Leakage Current
Output leakage current is current which flows in the DAC ladder switches when these are turned off. For the I_{OUT1} terminal, it can be measured by loading all 0s to the DAC and measuring the I_{OUT1} current. Minimum current will flow in the I_{OUT2} line when the DAC is loaded with all 1s.

Output Capacitance
This is the capacitance from the I_{OUT1} pin to AGND.

Output Voltage Settling Time
This is the amount of time it takes for the output to settle to a specified level for a full-scale input change. For these devices, it is specified both with the AD843 as the output op amp in the normal current mode and with the AD820 in the biased current mode.

Digital to Analog Glitch Impulse
This is the amount of charge injected into the analog output when the inputs change state. It is specified as the area of the glitch in nV-s. It is measured with the reference input connected to AGND and the digital inputs toggled between all 1s and all 0s. As with Settling Time, it is specified with both the AD817 and the AD820.

AC Feedthrough Error
This is the error due to capacitive feedthrough from the DAC reference input to the DAC I_{OUT1} terminal, when all 0s are loaded in the DAC.

Digital Feedthrough
When the device is not selected, high frequency logic activity on the device digital inputs is capacitively coupled through the device to show up as noise on the I_{OUT1} pin and subsequently on the op amp output. This noise is digital feedthrough.

DIP/SOP/SSOP

AD7943 PIN DESCRIPTION

Pin Mnemonic	Description
I_{OUT1}	DAC current output terminal 1.
I_{OUT2}	DAC current output terminal 2. This should be connected to the AGND pin.
AGND	This pin connects to the back gates of the current steering switches. In normal operation, it should be connected to the signal ground of the system. In biased single-supply operation it may be biased to some voltage between 0 V and the 1.23 V. See Figure 11 for more details.
STB 1	This is the Strobe 1 input. Data is clocked into the input shift register on the rising edge of this signal. $\overline{\text{STB 3}}$ must be high. STB 2, STB 4 must be low.
$\overline{\text{LD1}}$, $\overline{\text{LD2}}$	Active low inputs. When both of these are low, the DAC register is updated and the output will change to reflect this.
SRI	Serial Data Input. Data on this line will be clocked into the input shift register on one of the Strobe inputs, when they are enabled.
STB 2	This is the Strobe 2 input. Data is clocked into the input shift register on the rising edge of this signal. $\overline{\text{STB 3}}$ must be high. STB 1, STB 4 must be low.
$\overline{\text{STB 3}}$	This is the Strobe 3 input. Data is clocked into the input shift register on the falling edge of this signal. STB 1, STB 2, STB 4, must be low.
STB 4	This is the Strobe 4 input. Data is clocked into the input shift register on the rising edge of this signal. $\overline{\text{STB 3}}$ must be high. STB 1, STB 2 must be low.
DGND	Digital Ground.
$\overline{\text{CLR}}$	Asynchronous CLR input. When this input is taken low, all 0s are loaded to the DAC latch.
V_{DD}	Power supply input. This is nominally +5 V for Normal Mode Operation and +3.3 V to +5 V for Biased Mode Operation.
V_{REF}	DAC reference input.
R_{FB}	DAC feedback resistor pin.

AD7945 PIN DESCRIPTION

Pin Mnemonic	Description
I_{OUT1}	DAC current output terminal 1.
AGND	This pin connects to the back gates of the current steering switches. The DAC I_{OUT2} terminal is also connected internally to this point.
DGND	Digital Ground.
DB11–DB0	Digital Data Inputs.
$\overline{\text{CS}}$	Active Low, Chip Select Input.
$\overline{\text{WR}}$	Active Low, Write Input.
V_{DD}	Power supply input. This is nominally +5 V for Normal Mode Operation and +3.3 V to +5 V for Biased Mode Operation.
V_{REF}	DAC reference input.
R_{FB}	DAC feedback resistor pin.

AD7948 PIN DESCRIPTION

Pin Mnemonic	Description
I_{OUT1}	DAC current output terminal 1. Normally terminated at the virtual ground of output amplifier.
AGND	Analog Ground Pin. This pin connects to the back gates of the current steering switches. The DAC I_{OUT2} terminal is also connected internally to this point.
DGND	Digital Ground Pin.
$\overline{CSMSB}$	Chip Select Most Significant Byte. Active Low Input. Used in combination with $\overline{WR}$ to load external data into the input register or in combination with $\overline{LDAC}$ and $\overline{WR}$ to load external data into both input and DAC registers.
DF/$\overline{DOR}$	Data Format/Data Override. When this input is low, data in the DAC register is forced to one of two override codes selected by CTRL. When the override signal is removed, the DAC output returns to reflect the value in the DAC register. With DF/$\overline{DOR}$ high, CTRL selects either a left or right justified input data format. For normal operation, DF/$\overline{DOR}$ is held high. See Table I.

Table I. Truth Table for DF/$\overline{DOR}$ CTRL

DF/$\overline{DOR}$	CTRL	Function
0	0	DAC Register Contents Overridden by All 0s
0	1	DAC Register Contents Overridden by All 1s
1	0	Left-Justified Input Data Selected
1	1	Right-Justified Input Data Selected

CTRL	Control Input. See DF/$\overline{DOR}$ description.
DB7–DB0	Digital Data Inputs.
$\overline{LDAC}$	Load DAC input, active low. This signal, in combination with others, is used to load the DAC register from either the input register or the external data bus.
$\overline{CSLSB}$	Chip Select Least Significant (LS) Byte. Active Low Input. Used in combination with $\overline{WR}$ to load external data into the input register or in combination with $\overline{WR}$ and $\overline{LDAC}$ to load external data into both input and DAC registers.

Table II. Truth Table for AD7948 Write Operation

$\overline{WR}$	$\overline{CSMSB}$	$\overline{CSLSB}$	$\overline{LDAC}$	Function
0	1	0	1	Load LS Byte to Input Register
0	1	0	0	Load LS Byte to Input Register and DAC Register
0	0	1	1	Load MS Byte to Input Register
0	0	1	0	Load MS Byte to Input Register and DAC Register
0	1	1	0	Load Input Register to DAC Register
1	X	X	X	No Data Transfer

$\overline{WR}$	Write input, active low. This active low signal, in combination with others is used in loading external data into the AD7948 input register and in transferring data from the input register to the DAC register.
V_{DD}	Power supply input. This is nominally +5 V for Normal Mode Operation and +3.3 V to +5 V for Biased Mode Operation.
V_{REF}	DAC reference input.
R_{FB}	DAC feedback resistor pin.

GENERAL DESCRIPTION

D/A Section

The AD7943, AD7945 and AD7948 are 12-bit current-output D/A converters. A simplified circuit diagram is shown in Figure 13. The DAC architecture is segmented. This means that the 2 MSBs of the 12-bit data word are decoded to drive the three switches A, B and C. The remaining 10 bits of the data word drive the switches S0 to S9 in a standard inverting R-2R ladder configuration.

Each of the switches A to C steers 1/4 of the total reference current into either I_{OUT1} or I_{OUT2} with the remaining 1/4 of the total current passing through the R-2R section. Switches S9 to S0 steer binarily weighted currents into either I_{OUT1} or I_{OUT2}. If I_{OUT1} and I_{OUT2} are kept at the same potential, a constant current flows in each ladder leg, regardless of digital input code. Thus, the input resistance seen at V_{REF} is always constant. It is equal to R/2. The V_{REF} input may be driven by any reference voltage or current, ac or dc that is within the Absolute Maximum Ratings.

The device provides access to the V_{REF}, R_{FB}, and I_{OUT1} terminals of the DAC. This makes the device extremely versatile and allows it to be configured in several different operating modes. Examples of these are shown in the following sections. The AD7943 also has a separate I_{OUT2} pin. In the AD7945 and AD7948 this is internally tied to AGND.

When an output amplifier is connected in the standard configuration of Figure 14, the output voltage is given by:

$$V_{OUT} = -D \times V_{REF}$$

where D is the fractional representation of the digital word loaded to the DAC. D can be set from 0 to 4095/4096, since it has 12-bit resolution.

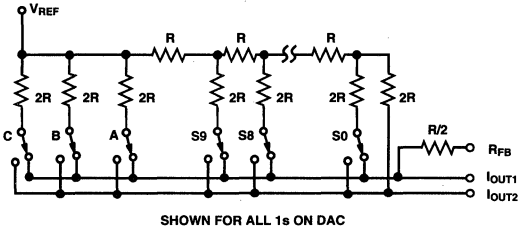

Figure 13. Simplified D/A Circuit Diagram

UNIPOLAR BINARY OPERATION

(Two-Quadrant Multiplication)

Figure 14 shows the standard unipolar binary connection diagram for the AD7943, AD7945 and AD7948. When V_{IN} is an ac signal, the circuit performs two-quadrant multiplication. Resistors R1 and R2 allow the user to adjust the DAC gain error. With a specified gain error of 2 LSBs over temperature, these are not necessary in many applications. Circuit offset is due completely to the output amplifier offset. It can be removed by adjusting the amplifier offset voltage. Alternatively, choosing a low offset amplifier makes this unnecessary.

A1 should be chosen to suit the application. For example, the OP07 is ideal for very low bandwidth applications (10 kHz or

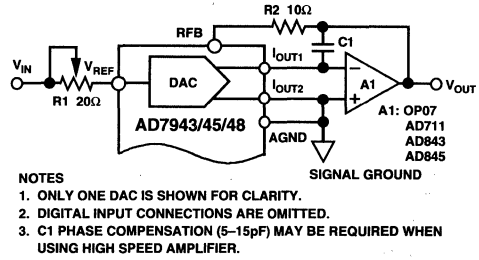

Figure 14. Unipolar Binary Operation

lower) while the AD711 is suitable for medium bandwidth applications (200 kHz or lower). For high bandwidth applications of greater than 200 kHz, the AD843 and AD847 offer very fast settling times.

The code table for Figure 14 is shown in Table III.

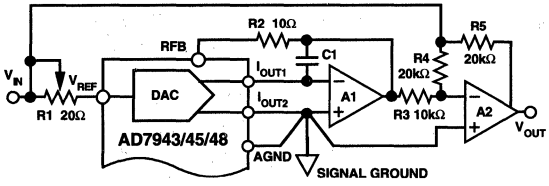
Table III. Unipolar Binary Code

Digital Input MSB LSB	Analog Output (V_{OUT} as Shown in Figure 15)
1111 1111 1111	$-V_{REF}$ (4095/4096)
1000 0000 0001	$-V_{REF}$ (2049/4096)
1000 0000 0000	$-V_{REF}$ (2048/4096)
0111 1111 1111	$-V_{REF}$ (2047/4096)
0000 0000 0001	$-V_{REF}$ (1/4096)
0000 0000 0000	$-V_{REF}$ (0/4096) = 0

NOTE
Nominal LSB size for the circuit of Figure 14 is given by: V_{REF} (1/4096).

BIPOLAR OPERATION
(Four-Quadrant Multiplication)

Figure 15 shows the standard connection diagram for bipolar operation of the AD7943, AD7945 and AD7948. The coding is offset binary as shown in Table IV. When V_{IN} is an ac signal, the circuit performs four-quadrant multiplication. Resistors R1 and R2 are for gain error adjustment and are not needed in many applications where the device gain error specifications are adequate. To maintain the gain error specifications, resistors R3, R4 and R5 should be ratio matched to 0.01%.



NOTES
1. ONLY ONE DAC IS SHOWN FOR CLARITY.
2. DIGITAL INPUT CONNECTIONS ARE OMITTED.
3. C1 PHASE COMPENSATION (5–15pF) MAY BE REQUIRED WHEN USING HIGH SPEED AMPLIFIER, A1.

Figure 15. Bipolar Operation (Four-Quadrant Multiplication)

Suitable dual amplifiers for use with Figure 15 are the OP270 (low noise, low bandwidth, 15 kHz), the AD712 (medium bandwidth, 200 kHz) or the AD827 (wide bandwidth, 1 MHz).

Table IV. Bipolar (Offset Binary) Code

Table Digital Input MSB LSB	Analog Output (V_{OUT} as Shown in Figure 16)
1111 1111 1111	$+V_{REF}$ (2047/2048)
1000 0000 0001	$+V_{REF}$ (1/2048)
1000 0000 0000	$+V_{REF}$ (0/2048) = 0
0111 1111 1111	$-V_{REF}$ (1/2048)
0000 0000 0001	$-V_{REF}$ (2047/2048)
0000 0000 0000	$-V_{REF}$ (2048/2048) = $-V_{REF}$

NOTE
Nominal LSB size for the circuit of Figure 15 is given by: V_{REF} (1/2048).

SINGLE SUPPLY APPLICATIONS

The "-B" versions of the devices are specified and tested for single supply applications. Figure 16 shows the recommended circuit for operation with a single +5 V to +3.3 V supply. The I_{OUT2} and AGND terminals are biased to 1.23 V. Thus, with 0 V applied to the V_{REF} terminal, the output will go from 1.23 V (all 0s loaded to the DAC) to 2.46 V (all 1s loaded). With 2.45 V applied to the V_{REF} terminal, the output will go from 1.23 V (all 0s loaded) to 0.01 V (all 1s loaded). It is important when considering INL in a single-supply system to realize that most single-supply amplifiers cannot sink current and maintain zero volts at the output. In Figure 16, with V_{REF} = 2.45 V the required sink current is 200 μA. The minimum output voltage level is 10 mV. Op amps like the OP295 are capable of maintaining this level while sinking 200 μA.

Figure 16 shows the I_{OUT2} and AGND terminals being driven by an amplifier. This is to maintain the bias voltage at 1.23 V as the impedance seen looking into the I_{OUT2} terminal changes. This impedance is code dependent and varies from infinity (all 0s loaded in the DAC) to about 6 kΩ minimum. The AD589 has a typical output resistance of 0.6 Ω and it can be used to drive the terminals directly. However, this will cause a typical linearity degradation of 0.2 LSBs. If this is unacceptable then the buffer amplifier is necessary. Figure 9 shows the typical linearity performance of the AD7943/AD7945/AD7948 when used as in Figure 16 with V_{DD} set at +3.3 V and V_{REF} = 0 V.

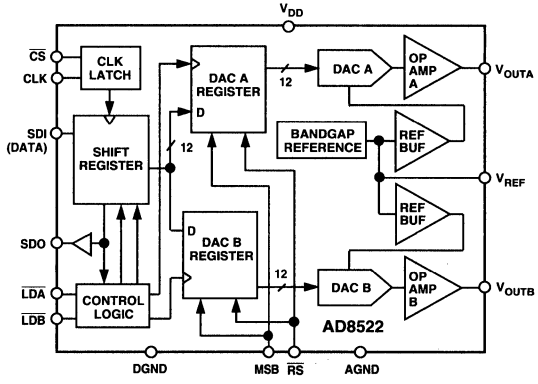
FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD8522 is a complete dual 12-bit, single-supply, voltage output DAC in a 14-pin DIP, or SO-14 surface mount package. Fabricated in a CBCMOS process, features include a serial digital interface, onboard reference, and buffered voltage output. Ideal for +5 V-only systems, this monolithic device offers low cost and ease of use, and requires no external components to realize the full performance of the device.

The serial digital interface allows interfacing directly to numerous microcontroller ports, with a simple high speed, three-wire data, clock, and load strobe format. The 16-bit serial word contains the 12-bit data word and DAC select address, which is decoded internally or can be decoded externally using $\overline{LDA}$, $\overline{LDB}$ inputs. A serial data output allows the user to easily daisy-chain multiple devices in conjunction with a chip select input. A reset $\overline{RS}$ input sets the outputs to zero scale or midscale, as determined by the input MSB.

The output 4.095 V full scale is laser trimmed to maintain accuracy over the operating temperature range of the device, and gives the user an easy-to-use one-millivolt-per-bit resolution. A 2.5 V reference output is also available externally for other data acquisition circuitry, and for ratiometric applications. The output buffers are capable of driving ±5 mA.

The AD8522 is available in the 14-pin plastic DIP and low profile 1.5 mm SOIC-14 packages.

NOTES
[1]1 LSB = 1 mV for 0 V to +4.095 V output range.
[2]Includes internal voltage reference error.
[3]These parameters are guaranteed by design and not subject to production testing.
[4]Very little sink current is available at the V_{REF} pin. Use external buffer if setting up a virtual ground.
[5]All input control signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.
[6]The settling time specification does not apply for negative going transitions within the last 6 LSBs of ground. Some devices exhibit double the typical settling time in this 6 LSB region.
[7]Power Dissipation is calculated $I_{DD} \times 5$ V.
Specifications subject to change without notice.

NOTES
[1]In software mode $\overline{LDA}$ and $\overline{LDB}$ perform the same function. They can be tied together or the unused pin should be tied high.
[2]External Pins $\overline{LDA}$ and $\overline{LDB}$ should always be high when shifting Data into the shift register.
[3]↓ symbol denotes negative transition.

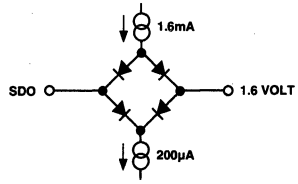

Figure 3. AC Timing SDO Pin Load Circuit

PIN DESCRIPTION

Pin	Function
SDI	Serial Data Input, input data loads directly into the shift register.
CLK	Clock input, positive edge clocks data into shift register.
$\overline{CS}$	Chip Select, active low input. Prevents shift register loading when high. Does not affect $\overline{LDA}$ and $\overline{LDB}$ operation.
$\overline{LDA}/\overline{B}$	Load DAC register strobes, active low. Transfers shift register data to DAC register. See truth table for operation. Software decode feature only requires one $\overline{LD}$ strobe. Tie $\overline{LDA}$ and $\overline{LDB}$ together or use one of them with the other pin tied high.
SDO	Serial Data Output. Output of shift register, always active.
$\overline{RS}$	Resets DAC registers to condition determined by MSB pin. Active low input.
MSB	Digital input: High presets DAC registers to half scale (800_H); Low clears all registers to zero (000_H), when $\overline{RS}$ is strobed to active low.
V_{DD}	Positive +5 V power supply input. Tolerance ±10%.
AGND	Analog Ground Input.
DGND	Digital Ground Input.
V_{REF}	Reference Voltage Output, 2.5 V nominal.
$V_{OUT\ A/B}$	DAC A/B voltage outputs, 4.095 V full scale, ±5 mA output.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option*
AD8522AN	–40°C to +85°C	14-Pin P-DIP	N-14
AD8522AR	–40°C to +85°C	14-Lead SOIC	SO-14
AD8522Chips	+25°C	Die	

*For outline information see Package Information section.

The AD8522 contains 1482 transistors.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD8522 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

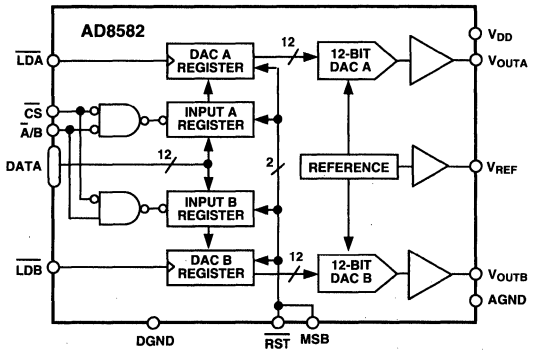
+5 Volt, Parallel Input Complete Dual 12-Bit DAC

AD8582

FEATURES
Complete Dual 12-Bit DAC
No External Components
Single +5 Volt Operation
1 mV/Bit with 4.095 V Full Scale
True Voltage Output, ±5 mA Drive
Very Low Power: 5 mW

APPLICATIONS
Digitally Controlled Calibration
Portable Equipment
Servo Controls
Process Control Equipment
PC Peripherals

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD8582 is a complete, parallel input, dual 12-bit, voltage output DAC designed to operate from a single +5 volt supply. Built using a CBCMOS process, this monolithic DAC offers the user low cost, and ease-of-use in +5 volt only systems.

Included on the chip, in addition to the DACs, are a rail-to-rail amplifier, latch and reference. The reference (V_{REF}) is trimmed to 2.5 volts output, and the on-chip amplifier gains up the DAC output to 4.095 volts full scale. The user needs only supply a +5 volt supply.

The AD8582 is coded natural binary. The op amp output swings from 0 volt to +4.095 volts for a one-millivolt-per-bit resolution, and is capable of driving ±5 mA. Operation down to 4.3 V is possible with output load currents less than 1 mA.

The high speed parallel data interface connects to the fastest processors without wait states. The double-buffered input structure allows the user to load the input registers one at a time, then a single load strobe tied to both LDA + LDB inputs will update both DAC outputs simultaneously. LDA and LDB can also be activated independently to immediately update their respective DAC registers. An address input decodes DAC A or DAC B when the chip select $\overline{CS}$ input is strobed. An asynchronous reset input sets the output to zero scale. The MSB bit can be used to establish a preset to midscale when the reset input is strobed.

The AD8582 is available in the 24-pin plastic DIP and the surface mount SOIC-24. Each part is fully specified for operation over –40°C to +85°C, and the full +5 V ± 5% power supply range.

PIN DESCRIPTION

Pin No.	Name	Description
1, 24	V_{OUTA} V_{OUTB}	Voltage outputs from the DACs. Fixed output voltage range of 0 V to 4.095 V with 1 mV/LSB. An internal temperature stabilized reference maintains a fixed full-scale voltage independent of time, temperature and power supply variations.
2	AGND	Analog Ground. Ground reference for the internal bandgap reference voltage, the DAC, and the output buffer.
3	DGND	Digital ground for input logic.
4, 21	$\overline{LDA}$, $\overline{LDB}$	Load DAC register strobes. Transfers input register data to the DAC registers. Active low inputs, Level sensitive latch. May be connected together to double-buffer load DAC registers.
5	MSB	Digital Input: High presets DAC registers to half scale (800_H), Low clears DAC registers to zero (000_H) upon $\overline{RST}$ assertion.
6	$\overline{RST}$	Active low digital input that clears the DAC register to zero, setting the DAC to minimum scale when MSB pin = 0, or half-scale when MSB pin = 1.
7–18	DB_{0-11}	Twelve Binary Data Bit Inputs. DB11 is the MSB and DB0 is the LSB.
19	$\overline{CS}$	Chip Select. Active low input.
20	$\overline{A}/B$	Select DAC A = 0 or DAC B = 1.
22	V_{DD}	Positive Supply. Nominal value +5 V, ±5%.
23	V_{REF}	Nominal 2.5 V reference output voltage. This node must be buffered if required to drive external loads.

OPERATION

The AD8582 is a complete, ready-to-use dual 12-bit digital-to-analog converter. Only one +5 V power supply is necessary for operation. It contains two voltage-switched, 12-bit, laser-trimmed digital-to-analog converters, a curvature-corrected bandgap reference, rail-to-rail output op amps, input registers, and DAC registers. The parallel data interface consists of twelve data bits, DB0–DB11, an address select pin $\overline{A}/B$, two load strobe pins ($\overline{LDA}$, $\overline{LDB}$) and an active low $\overline{CS}$ strobe. In addition an asynchronous $\overline{RST}$ pin will set all DAC register bits to zero causing the V_{OUT} to become zero volts, or to midscale for trimming applications when the MSB pin is programmed to Logic 1. This function is useful for power on reset or system failure recovery to a known state.

D/A CONVERTER SECTION

The internal DAC is a 12-bit voltage-mode device with an output that swings from AGND potential to the 2.5 volt internal bandgap voltage. It uses a laser trimmed R-2R ladder which is switched by N channel MOSFETs. The output voltage of the DAC has a constant resistance independent of digital input code. The DAC output (not available to the user) is internally connected to the rail-to-rail output op amp.

AMPLIFIER SECTION

The internal DAC's output is buffered by a low power consumption precision amplifier. This low power amplifier contains a differential PNP pair input stage which provides low offset voltage and low noise, as well as the ability to amplify the zero-scale DAC output voltages. The rail-to-rail amplifier is configured in a gain of 1.6384 (= 4.095 V/2.5 V) in order to set the 4.095 volt full-scale output (1 mV/LSB). See Figure 3 for an equivalent circuit schematic of the analog section.

The op amp has a 16 µs typical settling time to 0.01%. There are slight differences in settling time for negative slewing signals versus positive. See the oscilloscope photos in the Typical Performances section of this data sheet.

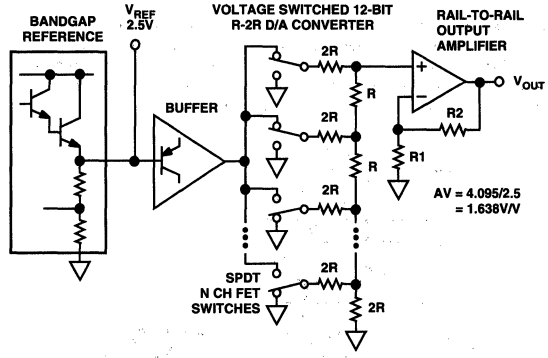

Figure 3. Equivalent Schematic of Analog Portion

OUTPUT SECTION

The rail-to-rail output stage of this amplifier has been designed to provide precision performance while operating near either power supply. Figure 4 shows an equivalent output schematic of the rail-to-rail amplifier with its N channel pull-down FETs that will pull an output load directly to GND. The output sourcing current is provided by a P channel pull-up device that can supply GND terminated loads, especially important at the –5% supply tolerance value of 4.75 volts.

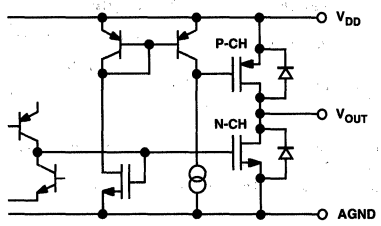

Figure 4. Equivalent Analog Output Circuit

Figures 5 and 6 in the typical performance characteristics section provide information on output swing performance near ground and full-scale as a function of load. In addition to resistive load driving capability, the amplifier has also been carefully designed and characterized for up to 500 pF capacitive load driving capability.

REFERENCE SECTION

The internal 2.5 V curvature-corrected bandgap voltage reference is laser trimmed for both initial accuracy and low temperature coefficient. The voltage generated by the reference is available at the V_{REF} pin. Since V_{REF} is not intended to drive external loads, it must be buffered. The equivalent emitter follower output circuit of the V_{REF} pin is shown in Figure 3.

Bypassing the V_{REF} pin will improve noise performance; however, bypassing is not required for proper operation. Figure 8 shows broadband noise performance.

POWER SUPPLY

The very low power consumption of the AD8582 is a direct result of a circuit design optimizing use of the CBCMOS process. By using the low power characteristics of the CMOS for the logic, and the low noise, tight matching of the complementary bipolar transistors good analog accuracy is achieved.

For power-consumption sensitive applications it is important to note that the internal power consumption of the AD8582 is strongly dependent on the actual logic-input voltage levels present on the DB0–DB11, $\overline{CS}$, A/B, MSB, $\overline{LDA}$, $\overline{LDB}$ and $\overline{RST}$ pins. Since these inputs are standard CMOS logic structures they contribute static power dissipation dependent on the actual driving logic V_{OH} and V_{OL} voltage levels. The graph in Figure 9 shows the effect on total AD8582 supply current as a function of the actual value of input logic voltage. Consequently, for optimum dissipation use of CMOS logic versus TTL provides minimal dissipation in the static state. A V_{INL} = 0 V on the DB0–11 pins provides the lowest standby dissipation of 1 mA typical with a +5 V power supply.

As with any analog system, it is recommended that the AD8582 power supply be bypassed on the same PC card that contains the chip. Figure 10 shows the power supply rejection versus frequency performance. This should be taken into account when using higher frequency switched-mode power supplies with ripple frequencies of 100 kHz and higher.

One advantage of the rail-to-rail output amplifiers used in the AD8582 is the wide range of usable supply voltage. The part is fully specified and tested over temperature for operation from +4.75 V to +5.25 V. If reduced linearity and source current capability near full scale can be tolerated, operation of the AD8582 is possible down to +4.3 volts. The minimum operating supply voltage versus load current plot, in Figure 1, provides information for operation below V_{DD} = +4.75 V.

TIMING AND CONTROL

The input registers are level triggered and acquire data from the data bus during the time period when $\overline{CS}$ is low. The input register selected is determined by the A/B select pin, see Table I. for a complete description. When $\overline{CS}$ goes high, the data is latched into the register and held until $\overline{CS}$ returns low. The minimum time required for the data to be present on the bus before $\overline{CS}$ returns high is called the data setup time (t_{DS}) as seen in Timing Diagram. The data hold time (t_{DH}) is the amount of time that the data has to remain on the bus after $\overline{CS}$ goes high. The high speed timing offered by the AD8582 provides for direct interface with no wait states in all but the fastest microprocessors.

The data from the input registers is transferred to the DAC registers by the active low $\overline{LDA}$ and $\overline{LDB}$ pins. If these inputs are tied together, a single logic input can perform a double buffer update of the DAC registers, which in turn simultaneously changes the analog output voltages to a new value. If the $\overline{LDA}$ and $\overline{LDB}$ pins are wired low, they become transparent. In this mode the input register data will directly control the output voltages. Refer to the Control Logic Truth Table for a complete description.

Unipolar Output Operation

This is the basic mode of operation for the AD8582. The AD8582 has been designed to drive loads as low as 820Ω in parallel with 500 pF. The code table for this operation is shown in Table II.

Table II. Unipolar Code Table

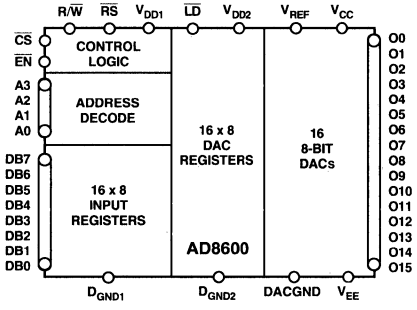
FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD8600 contains 16 independent voltage output digital-to-analog converters that share a common external reference input voltage. Each DAC has its own DAC register and input register to allow double buffering. An 8-bit parallel data input, four address pins, a $\overline{CS}$ select, a $\overline{LD}$, $\overline{EN}$, R/$\overline{W}$, and $\overline{RS}$ provide the digital interface.

The AD8600 is constructed in a monolithic CBCMOS process which optimizes use of CMOS for logic and bipolar for speed and precision. The digital-to-analog converter design uses voltage mode operation ideally suited to single supply operation. The internal DAC voltage range is fixed at DACGND to V_{REF}. The voltage buffers provide an output voltage range that approaches ground and extends to 1.0 V below V_{CC}. Changes in reference voltage values and digital inputs will settle within ±1 LSB in 2 μs.

Data is preloaded into the input registers one at a time after the internal address decoder selects the input register. In the write mode (R/$\overline{W}$ low) data is latched into the input register during the positive edge of the $\overline{EN}$ pulse. Pulses as short as 40 ns can be used to load the data. After changes have been submitted to the input registers, the DAC registers are simultaneously updated by a common load $\overline{EN} \times \overline{LD}$ strobe. The new analog output voltages simultaneously appear on all 16 outputs.

At system power up or during fault recovery the reset ($\overline{RS}$) pin forces all DAC registers into the zero state which places zero volts at all DAC outputs.

The AD8600 is offered in the PLCC-44 package. The device is designed and tested for operation over the extended industrial temperature range of –40°C to +85°C.

NOTES
[1]When V_{REF} = +3.500 V, 1 LSB = 13.67 mV.
[2]Guaranteed by design not subject to production test.
[3]Settling time test is performed using R_L = 50 kΩ and C_L = 35 pF.
[4]Power Dissipation is calculated using $5\ V \times (I_{DD} + |I_{SS}| + I_{DD1} + I_{DD2})$.
Specifications subject to change without notice.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD8600 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

ORDERING GUIDE

Model	Temperature	Package Description	Package Option[1]
AD8600AP	–40°C to +85°C	44-Lead PLCC	P-44A
AD8600Chips	+25°C	Die[2]	

NOTES
[1]For outline information see Package Information section.
[2]For die specifications contact your local Analog Devices sales office.
The AD8600 contains 5782 transistors.

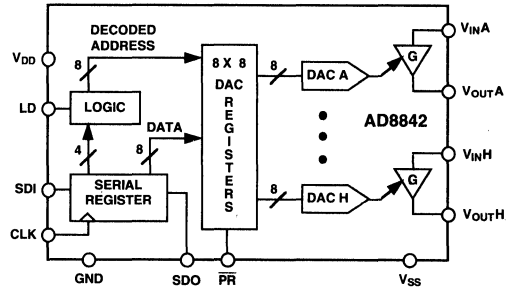
8-Bit Octal, 4-Quadrant Multiplying, CMOS TrimDAC

AD8842

FEATURES
Low Cost
Replaces 8 Potentiometers
50 kHz 4-Quadrant Multiplying Bandwidth
Low Zero Output Error
Eight Individual Channels
3-Wire Serial Input
500 kHz Update Data Loading Rate
±3 V Output Swing
Midscale Preset, Zero Volts Out

APPLICATIONS
Automatic Adjustment
Trimmer Replacement
Vertical Deflection Amplitude Adjustment
Waveform Generation and Modulation

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD8842 provides eight general purpose digitally controlled voltage adjustment devices. The TrimDAC® capability allows replacement of the mechanical trimmer function in new designs. The AD8842 is ideal for ac or dc gain control of up to 50 kHz bandwidth signals. The four-quadrant multiplying capability is useful for signal inversion and modulation often found in video vertical deflection circuitry.

Internally the AD8842 contains eight voltage output digital-to-analog converters, each with separate voltage inputs. A new current conveyor amplifier design performs the four-quadrant multiplying function with a single amplifier at the output of the current steering digital-to-analog converter. This approach offers an improved constant input resistance performance versus previous voltage switched DACs used in TrimDAC circuits, eliminating the need for additional input buffer amplifiers.

Each DAC has its own DAC register that holds its output state. These DAC registers are updated from an internal serial-to-parallel shift register that is loaded from a standard 3-wire serial input digital interface. Twelve data bits make up the data word clocked into the serial input register. This data word is decoded where the first 4 bits determine the address of the DAC register to be loaded with the last 8 bits of data. A serial data output pin at the opposite end of the serial register allows simple daisy chaining in multiple DAC applications without additional external decoding logic.

TrimDAC is a registered trademark of Analog Devices, Inc.
The current conveyor amplifier is a patented circuit belonging to Analog Devices, Inc.

The AD8842 consumes only 95 mW from ±5 V power supplies. For single 5 V supply applications consult the DAC-8841. The AD8842 is pin compatible with the 1 MHz multiplying bandwidth DAC8840. The AD8842 is available in 24-pin plastic DIP and surface mount SOL-24 packages.

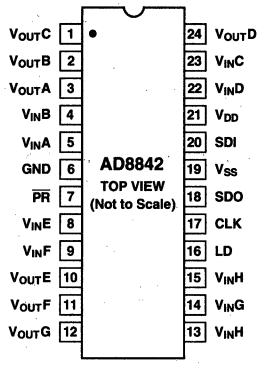
14	$V_{IN}G$	DAC G Reference Input
15	$V_{IN}H$	DAC H Reference Input
16	LD	Load DAC Register Strobe, active-high input that transfers the data bits from the serial-input register into the decoded DAC register. SDI and CLK inputs are disabled when LD is high. See Tables I and II
17	CLK	Serial Clock Input, positive edge triggered
18	SDO	Serial Data Output, active totem pole output
19	V_{SS}	Negative 5 V Power Supply
20	SDI	Serial Data Input
21	V_{DD}	Positive 5 V Power Supply
22	$V_{IN}D$	DAC D Reference Input
23	$V_{IN}C$	DAC C Reference Input
24	$V_{OUT}D$	DAC D Output

PIN CONFIGURATION



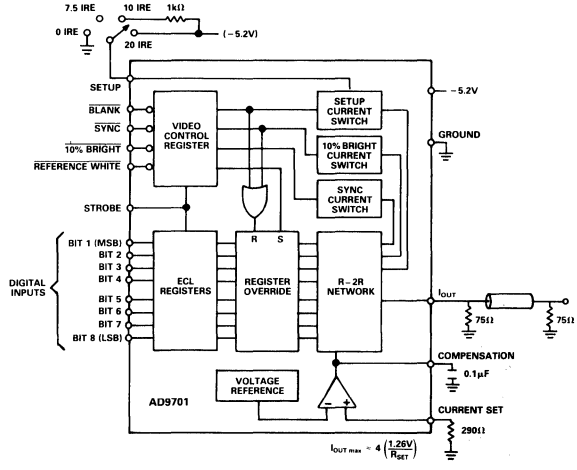
250MSPS Video Digital-to-Analog Converter

AD9701

FEATURES
250MSPS Update Rate
Low Glitch Impulse
Complete Composite Functions
Internal Voltage Reference
Single −5.2V Supply

APPLICATIONS
Raster Scan Displays
Color Graphics
Automated Test Equipment
TV Video Reconstruction

FUNCTIONAL BLOCK DIAGRAM



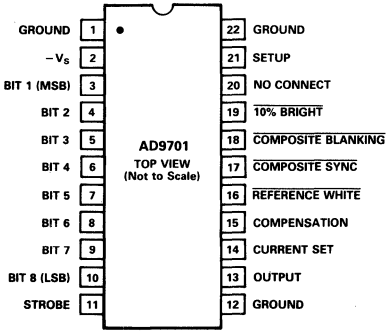
GENERAL DESCRIPTION

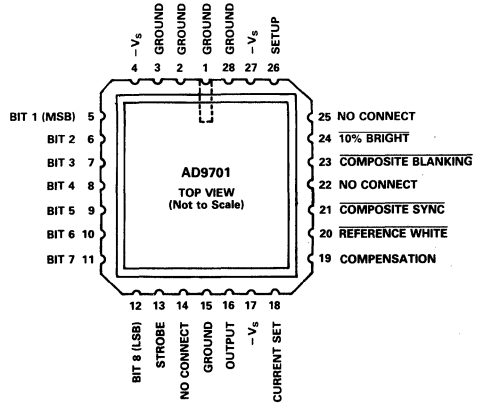
The AD9701 is a high-speed, 8-bit digital-to-analog converter with fully integrated composite video functions. High-speed ECL input registers provide synchronous operation of data and control functions up to 250MSPS.

The AD9701 incorporates on-board control functions including horizontal sync, blanking, reference white level, and a 10% bright signal for highlighting. The setup level is also adjustable from 0 IRE units to 20 IRE units, through the control pin. An internal voltage reference allows the AD9701 to operate as a stand-alone video reconstruction DAC.

The AD9701 is available as an industrial temperature range device, −25°C to +85°C, and as an extended temperature range device, −55°C to +125°C. Both grades of the AD9701 are packaged in a 22-pin ceramic DIP, with the extended temperature device also available in a 28-pin LCC package.

PIN CONFIGURATIONS





This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]Typical thermal impedance . . .
22-Pin Ceramic $\theta_{ja} = 64°C/W; \theta_{jc} = 16°C/W$
28-Pin Ceramic LCC $\theta_{ja} = 70°C/W; \theta_{jc} = 21°C/W$

[3]SYNC, BLANKING, and REFERENCE WHITE are inactive (Logic "1"). $I_{SET} \approx 1.26V/R_{SET}$.

[4]All bits at logic HIGH.

[5]All values are relative to full-scale output, after being normalized to nominal value. Typical variation in full-scale output from device to device can reach ±10%, for a fixed R_{SET} resistor.

[6]The effect of 10% BRIGHT algebraically adds to the output waveform.

[7]The output level with BLANKING active (Logic "0"), is determined by the setup control level.

[8]In normal operation, the BLANKING input is activated (Logic "0") prior to or in conjunction with the SYNC input. The effect of the SYNC output is relative to the setup level.

[9]Measured from edge of STROBE to 50% transition point of the output signal.

[10]Measured with full-scale change in output level, from the 10% transition level to within ±0.2% of the final output value.

[11]Measured from 10% to 90% transition point for full-scale step output.

[12]An IRE unit is 1% of the Grey Scale (GS range) with a 0 IRE setup level.

[13]Supply Voltage should remain stable within ±5% for normal operation.

[14]Measured at ±5% of $-V_S$.

Specifications subject to change without notice.

AD9701SE	−55°C to +125°C	28-Pin LCC, Extended Temperature	E-28A
AD9701SQ	−55°C to +125°C	22-Pin DIP, Extended Temperature	Q-22

*E = Leadless Ceramic Chip Carrier; Q = Cerdip. For outline information see Package Information section.

12-Bit, 100 MSPS D/A Converters

AD9712B/AD9713B

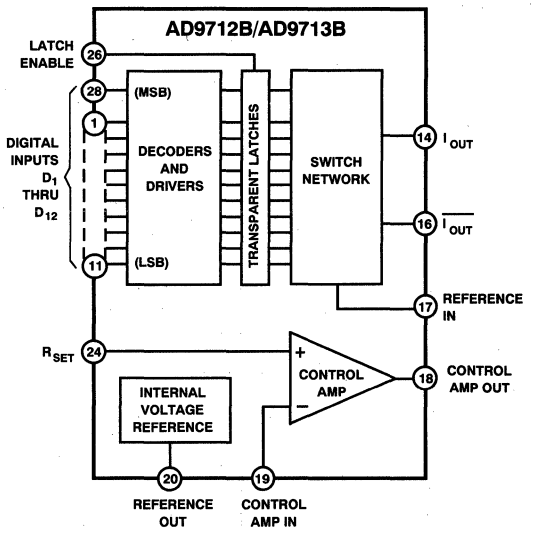
FEATURES
100 MSPS Update Rate
ECL/TTL Compatibility
SFDR @ 1 MHz: 70 dBc
Low Glitch Impulse: 28 pV-s
Fast Settling: 27 ns
Low Power: 725 mW
1/2 LSB DNL (B Grade)
40 MHz Multiplying Bandwidth

APPLICATIONS
ATE
Signal Reconstruction
Arbitrary Waveform Generators
Digital Synthesizers
Signal Generators

GENERAL DESCRIPTION

The AD9712B and AD9713B D/A converters are replacements for the AD9712 and AD9713 units which offer improved ac and dc performance. Like their predecessors, they are 12-bit, high speed digital-to-analog converters fabricated in an advanced oxide isolated bipolar process. The AD9712B is an ECL-compatible device featuring update rates of 100 MSPS minimum; the TTL-compatible AD9713B will update at 80 MSPS minimum.

FUNCTIONAL BLOCK DIAGRAM



Designed for direct digital synthesis, waveform reconstruction, and high resolution imaging applications, both devices feature low glitch impulse of 28 pV-s and fast settling times of 27 ns. Both units are characterized for dynamic performance and have excellent harmonic suppression.

The AD9712B and AD9713B are available in 28-pin plastic DIPs and PLCCs, with an operating temperature range of −25°C to +85°C. Both are also available for extended temperature ranges of −55°C to +125°C in cerdips and 28-pin LCC packages.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

ELECTRICAL CHARACTERISTICS [$-V_S = -5.2$ V; $+V_S = +5$ V (AD9713B only); Reference Voltage = -1.2 V; $R_{SET} = 7.5$ kΩ; $V_{OUT} = 0$ V (virtual ground); unless otherwise noted.]

NOTES
[1]Measured as error in ratio of full-scale current to current through R_{SET} (160 μA nominal); ratio is nominally 128.
[2]Full-scale variations among devices are higher when driving REFERENCE INPUT directly.
[3]Frequency at which the gain is flat ±0.5 dB; R_L = 50 Ω; 50% modulation at midscale.
[4]Based on I_{FS} = 128 (V_{REF}/R_{SET}) when using internal amplifier.
[5]Data registered into DAC accurately at this rate; does not imply settling to 12-bit accuracy.
[6]Measured as voltage settling at midscale transition to ±0.024%; R_L = 50 Ω.
[7]Measured as the time between the 50% point of the falling edge of LATCH ENABLE and the point where the output signal has left a 1 LSB error band around its previous value.
[8]Peak glitch impulse is measured as the largest area under a single positive or negative transient.
[9]Measured with R_L = 50 Ω and DAC operating in latched mode.
[10]Data must remain stable for specified time prior to falling edge of LATCH ENABLE signal.
[11]Data must remain stable for specified time after rising edge of LATCH ENABLE signal.
[12]SFDR is defined as the difference in signal energy between the fundamental and worst case spurious frequencies in the output spectrum window, which is centered at the fundamental frequency and covers the indicated span.
[13]Supply voltages should remain stable within ±5% for normal operation.
[14]108 mA typ on Digital $-V_S$, 37 mA typ on Analog $-V_S$.
[15]Measured at ±5% of $+V_S$ (AD9713B only) and $-V_S$ (AD9712B or AD9713B) using external reference.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

Positive Supply Voltage ($+V_S$) (AD9713B Only) . . . . . +6 V
Negative Supply Voltage ($-V_S$) . . . . . −7 V
Analog-to-Digital Ground Voltage Differential . . . . . 0.5 V
Digital Input Voltages (D_1–D_{12}, LATCH ENABLE)
AD9712B . . . . . 0 V to $-V_S$
AD9713B . . . . . −0.5 V to $+V_S$
Internal Reference Output Current . . . . . 500 μA
Control Amplifier Input Voltage Range . . . . . 0 V to −4 V
Control Amplifier Output Current . . . . . ±2.5 mA
Reference Input Voltage Range (V_{REF}) . . . . . 0 V to $-V_S$
Analog Output Current . . . . . 30 mA
Operating Temperature Range
AD9712B/AD9713BAN/AP/BN/BP . . . . . −25°C to +85°C
AD9712B/AD9713BSE/SQ/TE/TQ . . . . . −55°C to +125°C
Maximum Junction Temperature[2]
AD9712B/AD9713BAN/AP/BN/BP . . . . . +150°C
AD9712B/AD9713BSE/SQ/TE/TQ . . . . . +175°C
Lead Temperature (Soldering, 10 sec) . . . . . +300°C
Storage Temperature Range . . . . . −65°C to +150°C

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Typical thermal impedances with parts soldered in place: 28-pin plastic DIP: θ_{JA} = 37°C/W, θ_{JC} = 10°C/W; 28-pin PLCC: θ_{JA} = 44°C/W, θ_{JC} = 14°C/W; Cerdip: θ_{JA} = 32°C/W, θ_{JC} = 10°C/W; LCC: θ_{JA} = 41°C/W, θ_{JC} = 13°C/W. No air flow.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures.
III – Sample tested only.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

PIN DESCRIPTIONS

Pin #	Name	Function
1–10	D_2–D_{11}	Ten bits of twelve-bit digital input word.
11	D_{12} (LSB)	Least Significant Bit (LSB) of digital input word. **Input Coding vs. Current Output**

Input Code D_1–D_{12}	I_{OUT} (mA)	$\overline{I_{OUT}}$ (mA)
1111111111	−20.475	0
0000000000	0	−20.475

12	DIGITAL $-V_S$	One of two negative digital supply pins; nominally −5.2 V.
13	ANALOG RETURN	Analog ground return. This point and the reference side of the DAC load resistors should be connected to the same potential (nominally ground).
14	I_{OUT}	Analog current output; full-scale output occurs with digital inputs at all "1."
15	ANALOG $-V_S$	One of two negative analog supply pins; nominally −5.2 V.
16	$\overline{I_{OUT}}$	Complementary analog current output; zero scale output occurs with digital inputs at all "1."
17	REFERENCE IN	Normally connected to CONTROL AMP OUT (Pin 18). Direct line to DAC current source network. Voltage changes at this point have a direct effect on the full-scale output value of unit. Full-scale current output = 128 (Reference voltage/R_{SET}) when using internal amplifier.
18	CONTROL AMP OUT	Normally connected to REFERENCE INPUT (Pin 17). Output of internal control amplifier, which provides a temperature-compensated drive level to the current switch network.
19	CONTROL AMP IN	Normally connected to REFERENCE OUT (Pin 20) if not connected to external reference.
20	REFERENCE OUT	Normally connected to CONTROL AMP IN (Pin 19). Internal voltage reference, nominally −1.18 V.
21	DIGITAL $-V_S$	One of two negative digital supply pins; nominally −5.2 V.
22	REFERENCE GROUND	Ground return for the internal voltage reference and amplifier.
23	DIGITAL $+V_S$	Positive digital supply pin, used only on the AD9713B; nominally +5 V. No connection to this pin on AD9712B.
24	R_{SET}	Connection for external resistance reference. Full-scale current out = 128 (Reference voltage/R_{SET}) when using internal amplifier. Nominally 7.5 kΩ.
25	ANALOG $-V_S$	One of two negative analog supply pins; nominally −5.2 V.
26	LATCH ENABLE	Transparent latch control line. Register is transparent when LATCH ENABLE is LOW.
27	DIGITAL GROUND	Digital ground return.
28	D_1 (MSB)	Most Significant Bit (MSB) of digital input word.

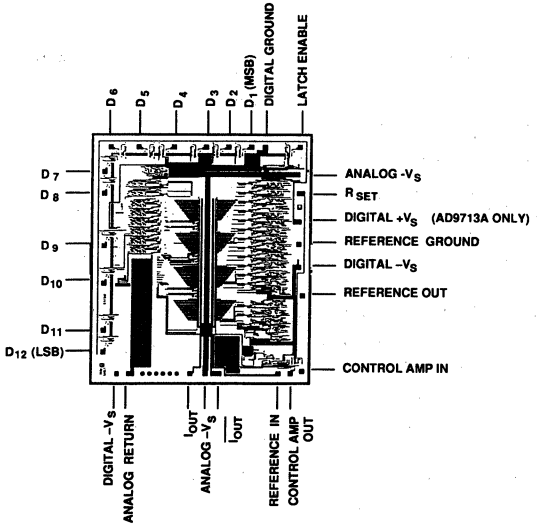
Substrate Potential	$-V_S$
Passivation	Nitride



THEORY AND APPLICATIONS

The AD9712B and AD9713B high speed digital-to-analog converters utilize Most Significant Bit (MSB) decoding and segmentation techniques to reduce glitch impulse and maintain 12-bit linearity without trimming.

As shown in the functional block diagram, the design is based on four main subsections: the Decoder/Driver circuits, the Transparent Latches, the Switch Network, and the Control Amplifier. An internal bandgap reference is also included to allow operation with a minimum of external components.

Digital Inputs/Timing

The AD9712B employs single-ended ECL-compatible inputs for data inputs D_1–D_{12} and LATCH ENABLE. The internal ECL midpoint reference is designed to match 10K ECL device thresholds. On the AD9713B, a TTL translator is added at each input; with this exception, the AD9712B and AD9713B are identical.

In the Decoder/Driver section, the four MSBs (D_1–D_4) are decoded to 15 "thermometer code" lines. An equalizing delay is included for the eight Least Significant Bits (LSBs) and LATCH ENABLE. This delay minimizes data skew, and data setup and hold times at the latch inputs; this is important when operating the latches in the transparent mode. Without the delay, skew caused by the decoding circuits would degrade glitch impulse.

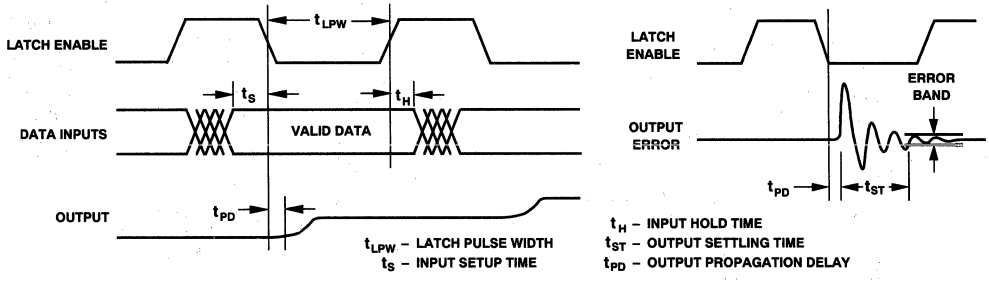
The latches operate in their transparent mode when LATCH ENABLE (Pin 26) is at logic level "0." The latches should be used to synchronize data to the current switches by applying a narrow LATCH ENABLE pulse with proper data setup and hold times as shown in the Timing Diagram. An external latch at each data input, clocked out of phase with the Latch Enable, operates the AD9712B/AD9713B in a master slave (edge-triggered) mode. This is the optimum way to operate the DAC because data is always stable at the DAC input. An external latch eases timing constraints when using the converter.

Although the AD9712B/AD9713B chip is designed to provide isolation from digital inputs to the outputs, some coupling of digital transitions is inevitable, especially with TTL or CMOS inputs applied to the AD9713B. Digital feedthrough can be reduced by forming a low-pass filter using a (200 Ω) series resistor in series with the capacitance of each digital input; this rolls off the slew rate of the digital inputs.

References

As shown in the functional block diagram, the internal band-gap reference, control amplifier, and reference input are pinned out for maximum user flexibility when setting the reference.

When using the internal reference, REFERENCE OUT (Pin 20) should be connected to CONTROL AMP IN (Pin 19). CONTROL AMP OUT (Pin 18) should be connected to REFERENCE IN (Pin 17) through a 20 Ω resistor. A 0.1 μF ceramic capacitor from Pin 17 to $-V_S$ (Pin 15) improves settling by decoupling switching noise from the current sink base line. A reference current cell provides feedback to the control amp by sinking current through R_{SET} (Pin 24).



Timing Diagram

Full-scale output current is determined by CONTROL AMP IN and R_{SET} according to the equation:

$$I_{OUT}\ (FS) = (CONTROL\ AMP\ IN/R_{SET}) \times 128$$

The internal reference is nominally −1.18 V with a tolerance of ±3.5% and typical drift over temperature of 50 ppm/°C. If greater accuracy or better temperature stability is required, an external reference can be utilized. The AD589 reference shown in Figure 1 features ±10 ppm/°C drift over temperatures from 0°C to +70°C.

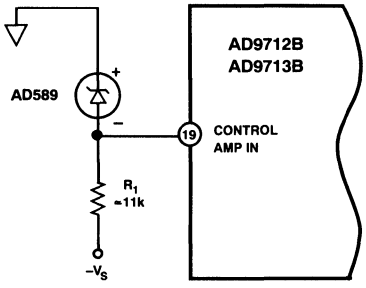


Figure 1. Use of AD589 as External Reference

Two modes of multiplying operation are possible with the AD9712B/AD9713B. Signals with small signal bandwidths up to 300 kHz and input swings of 100 mV, or dc signals from −0.6 V to −1.2 V can be applied to the CONTROL AMP input as shown in Figure 2. Because the control amplifier is internally compensated, the 0.1 μF capacitor at Pin 17 can be reduced to 0.01 μF to maximize the multiplying bandwidth. However, it should be noted that settling time for changes to the digital inputs will be degraded.

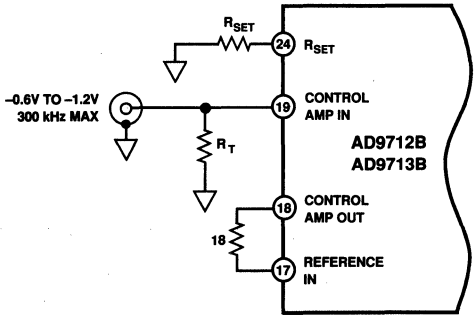

Figure 2. Low Frequency Multiplying Circuit

The REFERENCE IN pin can also be driven directly for wider bandwidth multiplying operation. The analog signal for this mode of operation must have a signal swing in the range of −3.75 V to −4.25 V. This can be implemented by capacitively coupling into REFERENCE IN a signal with a dc bias of −3.75 V to −4.25 V, as shown in Figure 3; or by driving REFERENCE IN with a low impedance op amp whose signal swing is limited to the stated range.

Outputs

As indicated earlier, D_1–D_4 (four MSBs) are decoded and drive 15 discrete current sinks. D5 and D6 are binarily weighted; and D_7–D_{12} are applied to the R-2R network. This segmented architecture reduces frequency domain errors due to glitch impulse.

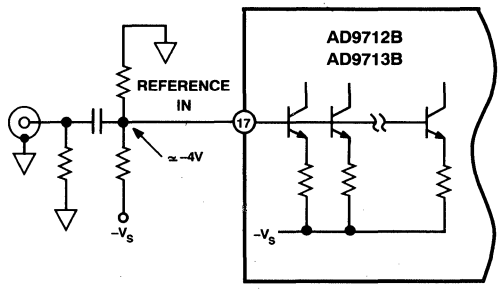

Figure 3. Wideband Multiplying Circuit

The Switch Network provides complementary current outputs I_{OUT} and $\overline{I_{OUT}}$. These current outputs are based on statistical current source matching which provides 12-bit linearity without trim. Current is steered to either I_{OUT} or $\overline{I_{OUT}}$ in proportion to the digital input code. The sum of the two currents is always equal to the full-scale output current minus one LSB.

The current output can be converted to a voltage by resistive loading as shown in Figure 4. Both I_{OUT} and $\overline{I_{OUT}}$ should be loaded equally for best overall performance. The voltage which is developed is the product of the output current and the value of the load resistor.

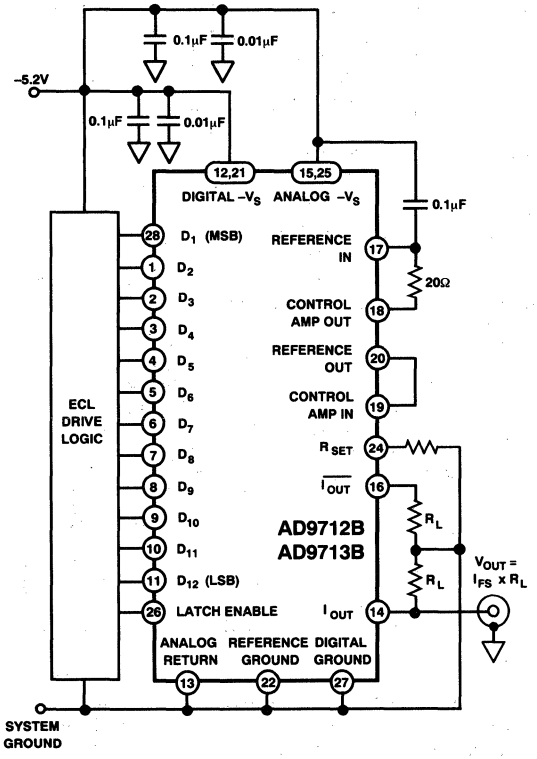

Figure 4. Typical Resistive Load Connection

An operational amplifier can also be used to perform the I to V conversion of the DAC output. Figure 5 shows an example of a circuit which uses the AD9617, a high speed, current feedback amplifier.

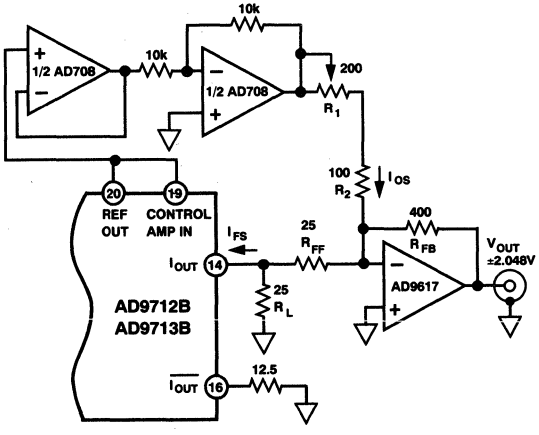

Figure 5. I/V Conversion Using Current Feedback

DAC current across feedback resistor R_{FB} determines the AD9617 output swing. A current divider formed by R_L and R_{FF} limits the current used in the I-to-V conversion, and provides an output voltage swing within the specifications of the AD9617. Current through R_2 provides dc offset at the output of the AD9617. Adjusting the value of R_1 adjusts the value of offset current. This offset current is based on the reference of the AD9712B/AD9713B, to avoid coupling noise into the output signal.

The resistor values in Figure 5 provide a 4.096 V swing, centered at ground, at the output of the AD9617 amplifier.

Power and Grounding

Maintaining low noise on power supplies and ground is critical for obtaining optimum results with the AD9712B or AD9713B. DACs are most often used in circuits which are predominantly digital. To preserve 12-bit performance, especially at conversion speeds up to 100 MSPS, special precautions are necessary for power supplies and grounding.

Ideally, the DAC should have a separate analog ground plane. All ground pins of the DAC, as well as reference and analog output components, should be tied directly to this analog ground plane. The DAC's ground plane should be connected to the system ground plane at a single point.

Ferrite beads such as the Stackpole 57-1392 or Amidon FB-43B-101, along with high frequency, low-inductance decoupling capacitors, should be used for the supply connections to isolate digital switching currents from the DAC supply pins. Separate isolation networks for the digital and analog supply connections will further reduce supply noise coupling to the output.

Molded socket assemblies should be avoided even when prototyping circuits with the AD9712B or AD9713B. When the DAC cannot be directly soldered into the board, individual pin sockets such as AMP #6-330808-0 (knock-out end), or #60330808-3 (open end) should be used. These have much less effect on inter-lead capacitance than do molded assemblies.

DDS Applications

Numerically controlled oscillators (NCOs) are digital devices which generate samples of a sine wave. When the NCO is combined with a high performance D/A converter (DAC), the combination system is referred to as a Direct Digital Synthesizer (DDS).

The digital samples generated by the NCO are reconstructed by the DAC and the resulting sine wave is usable in any system which requires a stable, spectrally pure, frequency-agile reference. The DAC is often the limiting factor in DDS applications, since it is the only analog function in the circuit. The AD9712B/AD9713B D/A converters offer the highest level of performance available for DDS applications.

DC linearity errors of a DAC are the dominant effect in low-frequency applications and can affect both noise and harmonic content in the output waveform. Differential Nonlinearity (DNL) errors determine the quantization error between adjacent codes, while Integral Nonlinearity (INL) is a measure of how closely the overall transfer function of the DAC compares with an ideal device. Together, these errors establish the limits of phase and amplitude accuracy in the output waveform.

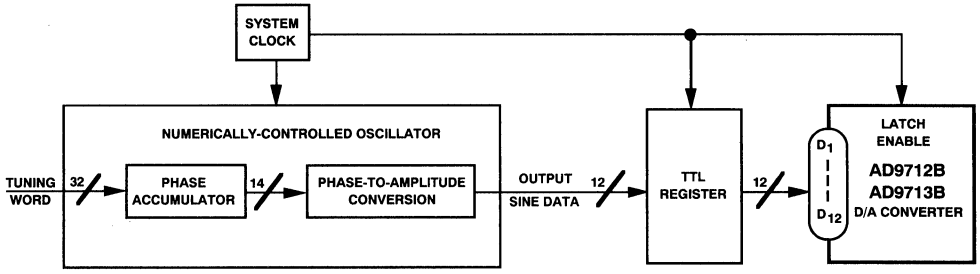

Figure 6. Direct Digital Synthesizer Block Diagram

When the analog frequency (f_A) is exactly f_C/N and N is an even integer, the DDS continually uses a small subset of the available DAC codes. The DNL of the converter is effectively the DNL error of the codes used, and is typically worse than the error measured against all available DAC codes. This increase in DNL is translated into higher harmonic and noise levels at the output.

Glitch impulse, often considered a figure of merit in DDS applications, is simply the initial transient response of the DAC as it moves between two output levels. This nonlinearity is commonly associated with external data skew, but this effect is minimized by using the on-board registers of the AD9712B/AD9713B converters (see Digital Inputs/Timing section). The majority of the glitch impulse, shown below, is produced as the current in the R-2R ladder network settles, and is fairly constant over the full-scale range of the DAC. The fast transients which form the glitch impulse appear as high-frequency spurs in the output spectrum.

While it is difficult to predict the effects of glitch on the output waveform, slew rate limitations translate directly into harmonics. This makes slew rate the dominant effect in ac linearity of the DAC. Applications in which the ratio of analog frequency (f_A) to clock frequency (f_C) is relatively high will benefit from the high slew rate and low output capacitance of the AD9712B/AD9713B devices.

Another concern in DDS applications is the presence of aliased harmonics in the output spectrum. Aliased harmonics appear as spurs in the output spectrum at frequencies which are determined by:

$$MfA \pm Nf_C$$

where M and N are integers.

The effects of these spurs are most easily observed in applications where f_A is nearly equal to an integer fraction of the clock rate. This condition causes the aliased harmonics to fold near the fundamental output frequency.

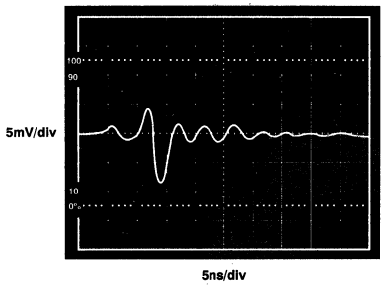

Figure 7. AD9712B/AD9713B Glitch Impulse

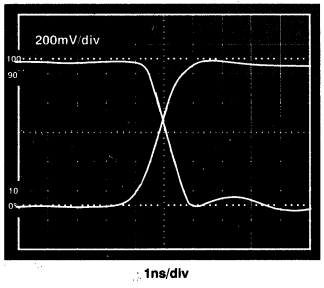

Figure 8. Rise and Fall Characteristics

10-Bit, 400 MSPS D/A Converters

AD9720/AD9721

FEATURES
400 MSPS (ECL)/100 MSPS (TTL) Update Rate
Low Glitch Impulse: 1.5 pV-s
Fast Settling: 4.5 ns to 1/2 LSB
Low Power: 1.1 W
On-Board Quadrature Logic for DDS Applications
Differential Clock (ECL)

APPLICATIONS
Direct Digital Synthesis
Arbitrary Waveform Synthesis
Waveform Reconstruction
High Speed Imaging

GENERAL DESCRIPTION

The AD9720 and AD9721 D/A converters are 10-bit, high speed digital-to-analog converters constructed in an oxide isolated bipolar process. The AD9720 is ECL compatible, and will update up to 400 Msps; the AD9721 is TTL compatible and will update up to 100 Msps.

Designed for direct digital synthesis (DDS), waveform reconstruction, and high resolution video applications, both devices feature low glitch impulse of 1.5 pV-s and fast settling times of 4.5 ns to 1/2 LSB.

Both converters are characterized for dynamic performance, and have excellent harmonic suppression and spectral purity in waveform generation applications.

The units are available in 28-pin DIPs, LCCs and SOICs. Industrial temperature range devices are packaged in plastic for operation from −25°C to +25°C; extended temperature range devices for operation from −55°C to +125°C are in hermetic ceramic packages. Contact the factory for information about the availability of MIL-STD-883 devices.

NOTES
[1]Measured as error in ratio of full-scale current to current through R_{SET} (640 μA nominal); ratio is nominally 32. DAC load is virtual ground.
[2]Full-scale current variations among devices are higher when driving REFERENCE IN directly.
[3]Frequency at which a 3 dB change in output of DAC is observed; R_L = 50 Ω; 100 mV modulation at midscale.
[4]Based on I_{FS} = 32 (CONTROL AMP IN/R_{SET}) when using internal control amplifier. DAC load is virtual ground.
[5]Measured as voltage settling at midscale transition to ±0.1%; R_L = 50 Ω.
[6]Measured from 50% point of rising edge of CLOCK signal to 1/2 LSB change in output signal.
[7]Peak glitch impulse is measured as the largest area under a single positive or negative transient.
[8]Measured with R_L = 50 Ω and DAC operating in latched mode.
[9]Data must remain stable for specified time prior to rising edge of CLOCK.
[10]Data must remain stable for specified time after rising edge of CLOCK.
[11]SFDR is defined as the difference in signal energy between the fundamental and worst case spurious frequencies in the output spectrum window, which is centered at the fundamental frequency and covers the indicated span.
[12]Supply voltages should remain stable within ±5% for normal operation.
[13]190 mA typ on Digital $-V_S$, 30 mA typ on Analog $-V_S$
[14]Measured at ±5% of $+V_S$ (AD9721 only) and $-V_S$ (AD9720 or AD9721) using external reference.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

I – 100% production tested.
II – 100% production tested at +25°C, and sample tested at specified temperatures.
III – Sample tested only.
IV – Parameter is guaranteed by design and characterization testing.
V – Parameter is a typical value only.
VI – All devices are 100% tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

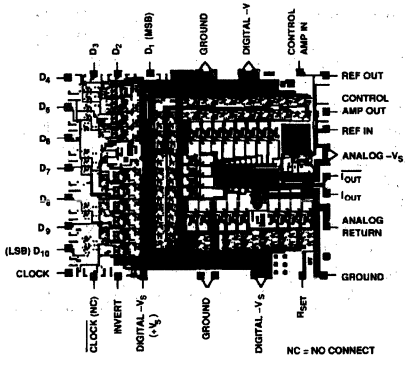
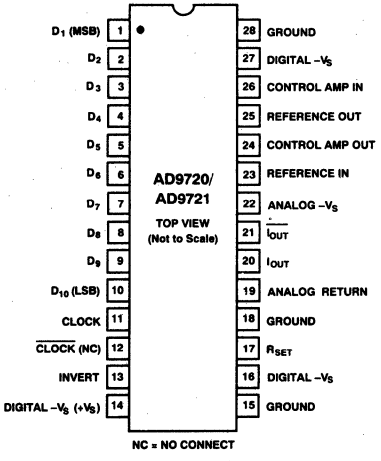
Passivation . . . . . Nitride

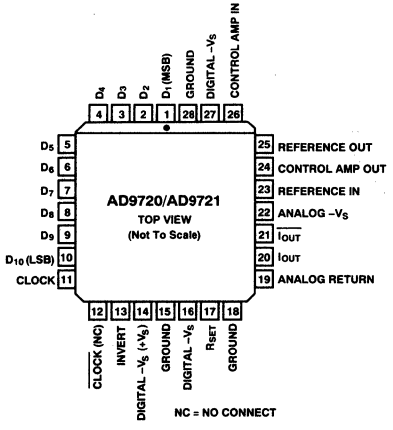


PIN DESCRIPTIONS

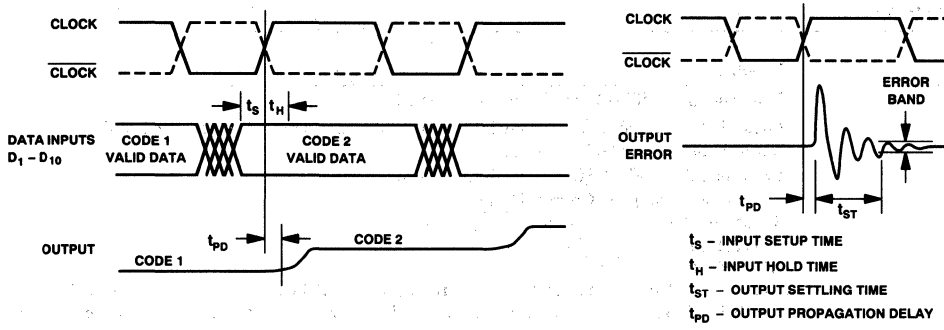
DIP Pin #	Name	Function
1	D_1 (MSB)	Most Significant Bit (MSB) of digital input word.
2–9	D_2–D_9	Eight of 10 digital input bits. Digital inputs are 10K ECL compatible for AD9720; TTL compatible for AD9721. See coding table elsewhere.
10	D_{10} (LSB)	Least Significant Bit (LSB) of digital input word. **Input Coding vs. Current Output** Input Code D_1–D_{10} I_{OUT} (mA) $\overline{I_{OUT}}$ (mA) 1111111111 −20.48 0 0000000000 0 −20.48
11	CLOCK	Edge-triggered latch enable signal for on-board registers. 10K ECL compatible for AD9720. TTL compatible for AD9721. Register loads data on rising edge of CLOCK signal; must be driven in conjunction with $\overline{\text{CLOCK}}$.
12	$\overline{\text{CLOCK}}$/NC	Complementary edge-triggered latch enable signal for on-board registers. 10K ECL compatible for AD9720; not connected (NC) for AD9721.
13	INVERT	Normally connected to logic LOW; inverters are transparent in this mode. Logic High inverts the 9 LSBs (D_2–D_{10}) when the MSB is LOW. No internal pull-down resistor.
14	DIGITAL $-V_S/+V_S$	One of three digital supply pins; nominally −5.2 V for AD9720; +5 V for AD9721.
15	GROUND	Converter ground return.
16	DIGITAL $-V_S$	One of three negative digital supply pins; nominally −5.2 V.
17	R_{SET}	Connection for external resistance reference; nominally 1,960 Ω. Full-scale current out = 32 × (CONTROL AMP IN/R_{SET}) when using internal amplifier. DAC load is virtual ground.
18	GROUND	Converter ground return.
19	ANALOG RETURN	Analog current return. This point and the reference side of the DAC load resistors should be connected to the same potential (nominally ground).
20	I_{OUT}	Analog current output; full-scale output occurs with digital inputs at all "1." With external load resistor, output voltage = $I_{OUT} \times (R_{LOAD} \parallel R_{INTERNAL})$. $R_{INTERNAL}$ is nominally 210 Ω.
21	$\overline{I_{OUT}}$	Complementary analog current output; zero-scale output occurs with digital inputs at all "1."
22	ANALOG $-V_S$	Negative analog supply; nominally −5.2 V.
23	REFERENCE IN	Normally connected to CONTROL AMP OUT (Pin 24). Direct line to DAC current source network. Voltage changes (noise) at this point have a direct effect on the full-scale output current of DAC. Full-scale current output = 32 × (CONTROL AMP IN/R_{SET}) when using internal amplifier. DAC load is virtual ground.
24	CONTROL AMP OUT	Normally connected to REFERENCE INPUT (Pin 23). Output of internal control amplifier, which provides a reference for the current switch network.
25	REFERENCE OUT	Normally connected to CONTROL AMP IN (Pin 26). Internal voltage reference, nominally −1.25 V.
26	CONTROL AMP IN	Normally connected to REFERENCE OUT (Pin 25) if not connected to external reference.
27	DIGITAL $-V_S$	One of three negative digital supply pins; nominally −5.2 V.
28	GROUND	Converter ground return.



Pinouts (SOIC Pin Numbering is Same as DIP)



LCC AD9720 (AD9721) Pinouts



AD9720/AD9721 Timing Diagram

THEORY AND APPLICATIONS

The AD9720/AD9721 high speed digital-to-analog converters utilize Most Significant Bit (MSB) decoding and segmentation techniques to reduce glitch impulse and maintain 10-bit linearity without trimming.

As shown in the functional block diagram, the design is based on four main subsections: the Decoder/Driver circuits, the Edge Triggered Data Register, the Switch Network, and the Control Amplifier. An internal bandgap reference is also included to allow operation with a minimum of external components. The block labeled "Inverters" is transparent in normal operation, but can be used to minimize the external components requirements in DDS applications using the AD9950, a 300 Msps phase accumulator (see AD9950 data sheet).

Digital Inputs/Timing

The AD9720 employs single-ended ECL-compatible inputs for data inputs D_1–D_{10} and the differential clock signals CLOCK and $\overline{\text{CLOCK}}$. The internal ECL midpoint reference is designed to match 10K ECL device thresholds. On the AD9721, a TTL translator is added at each input and the clock becomes single ended; with these exceptions, the AD9720 and AD9721 are identical. (NOTE: Pin 14 is $+V_S$ on AD9721; $-V_S$ on AD9720.)

In the Decoder/Driver section, the four MSBs (D_1– D_4) are decoded to 15 "thermometer code" lines. An equalizing delay is included for the six Least Significant Bits (LSBs) and the clock signals. This delay minimizes data skew and data setup and hold times at the register inputs.

The on-board register is rising-edge-triggered and should be used to synchronize data to the current switches by applying a pulse with proper data set-up and hold times as shown in the timing diagram.

Although the AD9720/AD9721 chip is designed to provide isolation from digital inputs to the outputs, some coupling of digital transitions is inevitable, especially with TTL or CMOS inputs applied to the AD9721. Digital feedthrough can be reduced by forming a low-pass filter using a resistor in series with the capacitance of each digital input; this rolls off the slew rate of the digital inputs.

References

As shown in the functional block diagram, the internal band-gap reference, control amplifier, and reference input are pinned out for maximum user flexibility when setting the reference.

When using the internal reference, REFERENCE OUT (Pin 25) should be connected to CONTROL AMP IN (Pin 26). CONTROL AMP OUT (Pin 24) should be connected to REFERENCE IN (Pin 23). A 0.1 μF ceramic capacitor from Pin 23 to ANALOG $-V_S$ (Pin 22) improves settling by decoupling switching noise from the current sink base line. A reference current cell provides feedback to the control amp by sinking current through R_{SET} (Pin 17).

Full-scale output current is determined by CONTROL AMP IN and R_{SET} according to the equation:

$$I_{OUT}\,(FS) = (CONTROL\ AMP\ IN/R_{SET}) \times 32$$

The internal reference is nominally −1.25 V with a tolerance of ±8% and typical drift over temperature of 100 ppm/°C. If greater accuracy or better temperature stability is required, an external reference can be utilized. The AD589 reference features ±10 ppm/°C drift over temperatures from 0°C to +70°C.

Two modes of multiplying operation are possible with the AD9720/9721. Signals with bandwidths up to 1 MHz and input swings from −0.6 V to −1.2 V can be applied to the CONTROL AMP input as shown in Figure 1. Because the control amplifier is internally compensated, the 0.1 μF capacitor discussed above can be reduced to maximize the multiplying bandwidth. However, it should be noted that settling time for changes to the digital inputs will be degraded.

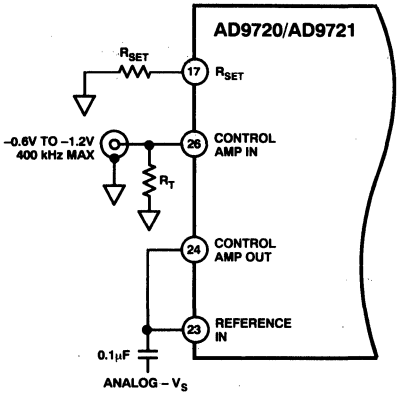


Figure 1. Low Frequency Multiplying Circuit

The REFERENCE IN pin can also be driven directly for wider bandwidth multiplying operation. The analog signal for this mode of operation must have a signal swing in the range of −3.3 V to −4.25 V. This can be implemented by capacitively coupling into REFERENCE IN a signal with a dc bias of −3.3 V (I_{OUT} ~ 22.5 mA) to −4.25 V (I_{OUT} ~ 3 mA), as shown in Figure 2, or by driving REFERENCE IN with a low impedance op amp whose signal swing is limited to the stated range.

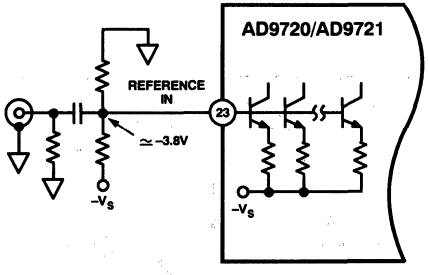

Figure 2. Wideband Multiplying Circuit

Outputs

The Switch Network provides complementary current outputs I_{OUT} and $\overline{I_{OUT}}$. The design of the AD9720/AD9721 is based on statistical current source matching which provides 10-bit linearity without trim. Current is steered to either I_{OUT} or $\overline{I_{OUT}}$ in proportion to the digital input code. The sum of the two currents is always equal to the full-scale output current minus one LSB.

The current output can be converted to a voltage by resistive loading as shown in the block diagram. Both I_{OUT} and $\overline{I_{OUT}}$ should be loaded equally for best overall performance. The voltage which is developed is the product of the output current and the value of the load resistor.

An operational amplifier can also be used to perform the I to V conversion of the DAC output. Figure 3 shows an example of a circuit which uses the AD9617, a high speed, current feedback amplifier. The resistor values in Figure 3 provide a 4.096 V swing, centered at ground, at the output of the AD9617 amplifier.

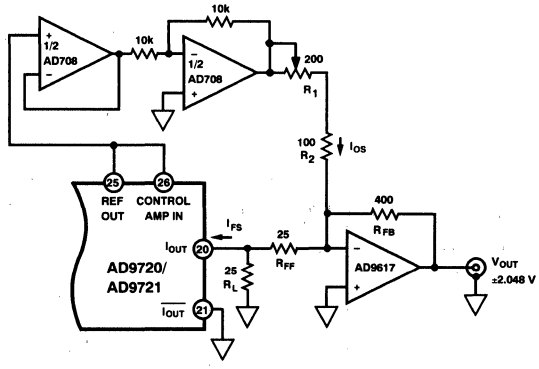

Figure 3. I/V Conversion Using Current Feedback Amp

DDS Applications

The performance characteristics of the AD9720/AD9721 make it ideally suited for direct digital synthesis (DDS) and other waveform generation applications. Since the aliased distortion of the DAC collects around the fundamental when generating frequencies which are nearly integer fractions of the clock rate, these are often considered worst case conditions.

Please contact the factory for information concerning the availability of an evaluation board or for additional characterization data.

APPLICATIONS
Raster Scan & Vector Graphic Displays
High Speed Waveform Generation
Digital VCOs
Ultra-Fast Digital Attenuators

GENERAL DESCRIPTION

The Analog Devices AD9768SD D/A converter is a monolithic current-output converter which can accept 8 bits of ECL-level digital input voltages and convert them into analog signals at update rates as high as 100MSPS. In addition to its use as a standard D/A converter, it can also be utilized as a two-quadrant multiplying D/A at multiplying bandwidths as high as 40MHz.

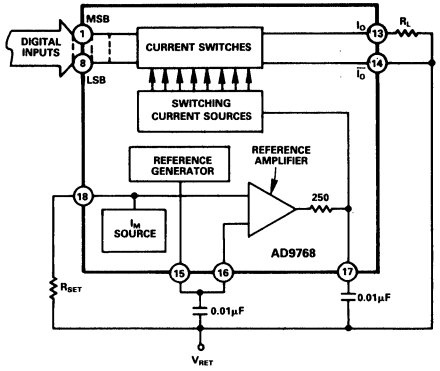
An inherently low glitch design is used, and the complementary current outputs are suitable for driving transmission lines directly. Nominal full-scale output is 20mA, which corresponds to a 1-volt drop across a 50Ω load, or ±1 volt across 100Ω returned to +1 volt. The actual output current is determined by the on-chip reference voltage ($V_{REF} \approx -1.26V$) and an external current setting resistor, R_{SET}.

Full-scale output current I_{OUT} with digital "1" at all inputs is calculated with the equation:

$$I_{OUT} = 4 \times \frac{V_{RET} - V_{REF}}{R_{SET}}$$

The setting resistor R_{SET} and the output load resistor should both have low temperature coefficients. A complementary $\overline{I_{OUT}}$ is also provided.

FUNCTIONAL BLOCK DIAGRAM



The reference voltage source is a modified bandgap type and is nominally −1.26 volts. This reference supply requires no external regulation. To reduce the possibility of noise generation and/or instability, pin 15 (REFERENCE OUT) can be decoupled using a high-quality ceramic chip capacitor. Stabilization of the internal loop amplifier is by a single capacitor connected from pin 17 (COMPENSATION) to ground. The minimum value for this capacitor is 3900pF, although a 0.01μF ceramic chip capacitor is recommended.

The incredible speed characteristics of the AD9768SD D/A converter make it attractive for a wide range of high speed applications. The ability of the unit to operate as a two-quadrant multiplying D/A converter adds another dimension to its usefulness and makes the AD9768SD a truly versatile device.

AD9768SD D/A Schematic

ANALOG DEVICES

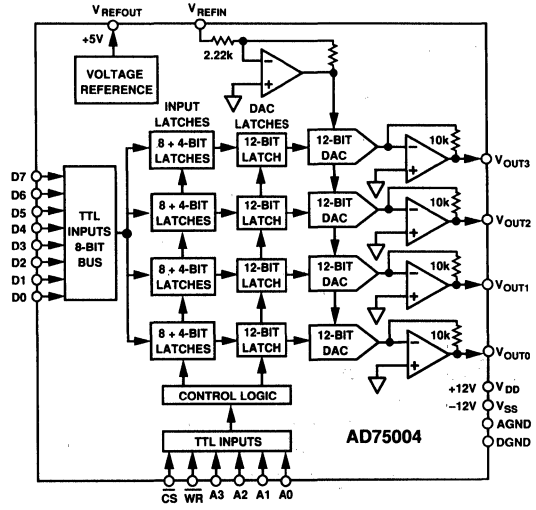
Quad 12-Bit D/A Converter

AD75004

FEATURES

4 Complete 12-Bit D/A Functions
Double-Buffered Latches
Simultaneous Update of All DACs Possible
±5 V Output Range
High Stability Bandgap Reference
Monolithic BiMOS Construction
Guaranteed Monotonic over Temperature
3/4 LSB Linearity Guaranteed over Temperature
4 μs max Settling Time to 0.01%
Operates with ±12 V Supplies
Low Power: 720 mW max Including Reference
TTL/5 V CMOS Compatible Logic Inputs
8-Bit Microprocessor Interface
24-Pin PDIP or 28-Lead PLCC Package

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD75004 contains four complete, voltage output, 12-bit digital-to-analog converters, a high stability bandgap reference, and double-buffered input latches on a single chip. The converters use 12 precision high speed bipolar current steering switches and laser-trimmed thin-film resistor networks to provide fast settling time and high accuracy.

Microprocessor compatibility is achieved by the on-chip double-buffered latches. The design of the input latches allows direct interface to 8-bit buses. The 12 bits of data from the first rank of latches can then be transferred to the second rank, avoiding generation of spurious analog output values. The latch responds to strobe pulses as short as 50 ns, allowing use with fast microprocessors.

The functional completeness and high performance of the AD75004 results from a combination of advanced switch design, the BiMOS II fabrication process, and proven laser trimming technology. BiMOSII is an epitaxial BiCMOS process optimized for analog and converter functions. The AD75004 is trimmed at the wafer level and is specified to ±1/2 LSB maximum linearity error at 25°C and ±3/4 LSB over the full operating temperature range. The on-chip output amplifiers provide an output range of ±5 V, with 1 LSB equal to 2.44 mV.

The bandgap reference on the chip has low noise, long term stability and temperature drift characteristics comparable to discrete reference diodes. The absolute value of the reference is laser trimmed to +5.00 V with 0.6% maximum error. Its temperature coefficient is also laser trimmed.

Typical full-scale gain TC is 15 ppm/°C. With guaranteed monotonicity over the full temperature range, the AD75004 is well suited for wide temperature range performance.

AD75004—SPECIFICATIONS (T_A = +25°C, ±12.0 V power supplies unless otherwise noted)

NOTES

[1]Gain and bipolar zero errors are measured using internal voltage reference and include its errors.

[2]Digital crosstalk is defined as the change in any one output's steady state value as a result of any other output being driven from V_{OUTMIN} to V_{OUTMAX} into a 2 kΩ || 500 pF load by means of varying the digital input code.

[3]The internal voltage reference is intended to drive on-chip only; buffer it if using it externally.

[4]All minimum and maximum specifications are guaranteed, and specifications shown in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels.

Specifications subject to change without notice.

0	0	1	0	A1*	A0*	Update one DAC latch
0	0	1	1	X	X	Update all 4 DAC latches

NOTE
*The A1 and A0 inputs specify the relevant channel.

A1	A0	Channel
0	0	0
0	1	1
1	0	2
1	1	3

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are Zener protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

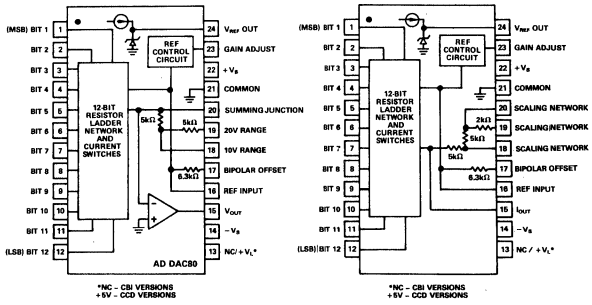
Complete Low Cost 12-Bit D/A Converters

AD DAC80/AD DAC85/AD DAC87

FEATURES

- Single Chip Construction
- On-Board Output Amplifier
- Low Power Dissipation: 300mW
- Monotonicity Guaranteed over Temperature
- Guaranteed for Operation with ±12V Supplies
- Improved Replacement for Standard DAC80, DAC800 HI-5680
- High Stability, High Current Output Buried Zener Reference
- Laser Trimmed to High Accuracy: ±1/2LSB max Nonlinearity
- Low Cost Plastic Packaging

FUNCTIONAL BLOCK DIAGRAMS



PRODUCT DESCRIPTION

The AD DAC80 Series is a family of low cost 12-bit digital-to-analog converters with both a high stability voltage reference and output amplifier combined on a single monolithic chip. The AD DAC80 Series is recommended for all low cost 12-bit D/A converter applications where reliability and cost are of paramount importance.

Advanced circuit design and precision processing techniques result in significant performance advantages over conventional DAC80 devices. Innovative circuit design reduces the total power consumption to 300mW which not only improves reliability but also improves long term stability.

The AD DAC80 incorporates a fully differential, non-saturating precision current switching cell structure which provides greatly increased immunity to supply voltage variation. This same structure also reduces nonlinearities due to thermal transients as the various bits are switched; nearly all critical components operate at constant power dissipation. High stability, SiCr thin film resistors are trimmed with a fine resolution laser, resulting in lower differential nonlinearity errors. A low noise, high stability, subsurface Zener diode is used to produce a reference voltage with excellent long term stability, high external current capability and temperature drift characteristics which challenge the best discrete Zener references.

The AD DAC80 Series is available in three performance grades and two package types. The AD DAC80 is specified for use over the 0 to +70°C temperature range and is available in both plastic and ceramic DIP packages. The AD DAC85 and AD DAC87 are available in hermetically sealed ceramic packages and are specified for the −25°C to +85°C and −55°C to +125°C temperature ranges.

PRODUCT HIGHLIGHTS

1. The AD DAC80 series of D/A converters directly replaces all other devices of this type with significant increases in performance.
2. Single chip construction and low power consumption provides the optimum choice for applications where low cost and high reliability are major considerations.
3. The high speed output amplifier has been designed to settle within 1/2LSB for a 10V full scale transition in 2.0μs, when properly compensated.
4. The precision buried Zener reference can supply up to 2.5mA for use elsewhere in the application.
5. The low TC binary ladder guarantees that all units are monotonic over the specified temperature range.
6. System performance upgrading is possible without redesign.

PRODUCT OFFERING

Analog Devices has developed a number of technologies to support products within the data acquisition market. In serving the market new products are implemented with the technology best suited to the application. The DAC80 series of products was first implemented in hybrid form and now it is available in a single monolithic chip. We will provide both the hybrid and monolithic versions of the family so that in existing designs changes to documentation or product qualification will not have to be done. Specifications and ordering information for both versions are delineated in this data sheet.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Least Significant Bit.

[2]Adjustable to zero with external trim potentiometer.

[3]FSR means "Full Scale Range" and is 20V for the ±10V range and 10V for the ±5V Range.

[4]Gain and offset errors adjusted to zero at +25°C.

[5]C_V = 0, see Figure 1a.

[6]Maximum with no degradation of specification, must be a constant load.

[7]A minimum of ±12.3V is required for a ±10V full scale output and ±11.4V is required for all other voltage ranges.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

**Z-Suffix devices guarantee performance of 0 to +5V and ±5V spans with minimum supply voltages of ±11.4V.

8-Bit, High Speed, Multiplying D/A Converter (Universal Digital Logic Interface)

DAC08

FEATURES

- Fast Settling Output Current 85ns
- Full-Scale Current Prematched to ±1 LSB
- Direct Interface to TTL, CMOS, ECL, HTL, PMOS
- Nonlinearity to 0.1% Maximum Over Temperature Range
- High Output Impedance and Compliance ..... −10V to +18V
- Complementary Current Outputs
- Wide Range Multiplying Capability ... 1MHz Bandwidth
- Low FS Current Drift ..... ±10ppm/°C
- Wide Power Supply Range ..... ±4.5V to ±18V
- Low Power Consumption ..... 33mW @ ±5V
- Low Cost
- Available in Die Form

GENERAL DESCRIPTION

The DAC-08 series of 8-bit monolithic digital-to-analog converters provide very high-speed performance coupled with low cost and outstanding applications flexibility.

Advanced circuit design achieves 85ns settling times with very low "glitch" energy and at low power consumption. Monotonic multiplying performance is attained over a wide 20 to 1 reference current range. Matching to within 1 LSB between reference and full-scale currents eliminates the need for full-scale trimming in most applications. Direct interface to all popular logic families with full noise immunity is provided by the high swing, adjustable threshold logic input.

High voltage compliance complementary current outputs are provided, increasing versatility and enabling differential operation to effectively double the peak-to-peak output swing. In many applications, the outputs can be directly converted to voltage without the need for an external op amp.

All DAC-08 series models guarantee full 8-bit monotonicity, and nonlinearities as tight as ±0.1% over the entire operating temperature range are available. Device performance is essentially unchanged over the ±4.5 to ±18V power supply range, with 33mW power consumption attainable at ±5V supplies.

The compact size and low power consumption make the DAC-08 attractive for portable and military/aerospace applications; devices processed to MIL-STD-883, Level B are available.

DAC-08 applications include 8-bit, 1μs A/D converters, servo motor and pen drivers, waveform generators, audio encoders and attenuators, analog meter drivers, programmable power supplies, CRT display drivers, high-speed modems and other applications where low cost, high speed and complete input/output versatility are required.

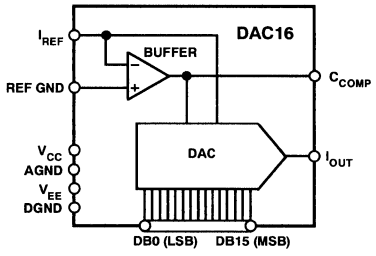
FUNCTIONAL BLOCK DIAGRAM



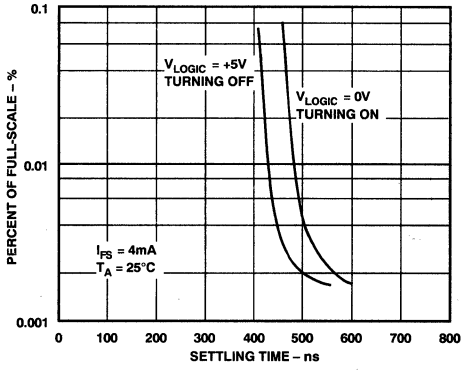


Figure 1. DAC16 Settling Time Accuracy vs. Percent of Full Scale

GENERAL DESCRIPTION

The DAC16 is a 16-bit high speed current-output digital-to-analog converter with a settling time of 500 ns. A unique combination of low distortion, high signal-to-noise ratio, and high speed make the DAC16 ideally suited to performing waveform synthesis and modulation in communications, instrumentation, and ATE systems. Input reference current is buffered, with full-scale output current of 5 mA. The 16-bit parallel digital input bus is TTL/CMOS compatible. Operating from +5 V and −15 V supplies, the DAC16 consumes 190 mW (typ) and is available in a 24-pin epoxy DIP, epoxy surface-mount small outline (SOL), ceramic side brazed DIP, 28-pin leadless ceramic chip carrier (LCC) packages, and in die form.

NOTE
[1]θ_{JA} is specified for worst case mounting conditions, i.e., θ_{JA} is specified for device in socket.

CAUTION

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected; however, permanent damage may occur on unprotected units from high energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper antistatic handling procedures.
3. Remove power before inserting or removing units from their sockets.

OPERATION

Novel DAC Architecture

The DAC16 was designed with a compound DAC architecture to achieve high accuracy, excellent linearity, and low transition errors. As shown in Figure 3, the DAC's five most-significant bits utilize 31 identical segmented current sources to obtain optimal high speed settling at major code transitions. The lower nine bits utilize an inverted R–2R ladder network which is laser-trimmed to ensure excellent differential nonlinearity. The middle two bits (DB9 and DB10) are binary-weighted and scaled from the MSB segments. Note that the flow of output current is into the DAC16—there is no signal inversion. As shown, the switches for each current source are essentially diodes. It is for this reason that the output voltage compliance of the DAC16 is limited to a few millivolts. The DAC16 was designed to operate with an operational amplifier configured as an I–V converter; therefore, the DAC16's output must be connected to the sum node of an operational amplifier for proper operation. Exceeding the output voltage compliance of the DAC16 will introduce linearity errors. The reference current buffer assures full accuracy and fast settling by controlling the MSB reference node. The 16-bit parallel digital input is TTL/CMOS compatible and unbuffered, minimizing the deleterious effects of digital feedthrough while allowing the used to tailor the digital interface to the speed requirements and bus configuration of the application.

Equivalent Circuit Analysis

An equivalent circuit for static operation of the DAC16 is illustrated in Figure 4. I_{REF} is the current applied to the DAC16 and is set externally to the device by V_{REF} and R_{REF}. The output capacitance of the DAC16 is approximately 10 pF and is code independent. Its output resistance R_O is code dependent and is given by:

$$\frac{1}{R_O} = \frac{1}{8\ k\Omega} + \frac{DB9}{288\ k\Omega} + \frac{DB10}{144\ k\Omega} + \frac{X}{72\ k\Omega}$$

where

DB9 = State of Data Bit 9 = 0 or 1;

DB10 = State of Data Bit 10 = 0 or 1; and

X = Decimal representation of the 5 MSBs (DB11– DB15) = 0 to 31.

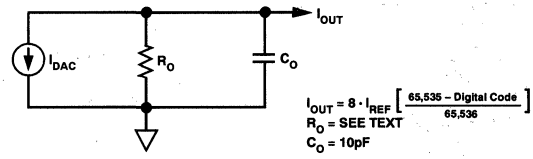

Figure 4. Equivalent Circuit for the DAC16

Table I provides the relationship between the input digital code and the output resistance of the DAC16.

Table I. DAC16 Output Resistance vs. Digital Code

Hex Digital Code	Scale	Output Resistance
FFFF	Zero	8 kΩ
BFFF	1/4	4.2 kΩ
7FFF	1/2	2.9 kΩ
3FFF	3/4	2.2 kΩ
0	Full – 1 LSB	1.8 kΩ

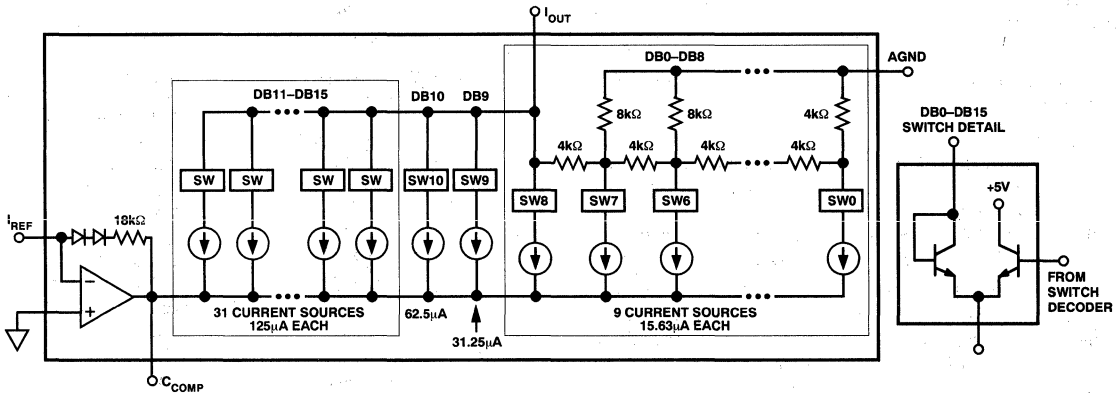

Figure 3. DAC16 Architecture

Digital Input Considerations

The threshold of the DAC16's digital input circuitry is set at 1.4 V, independent of supply voltage. Hence, the digital inputs can interface with any type of 5 V logic. Illustrated in Figure 5 is the equivalent circuit of the digital inputs. Note that the individual input capacitance is approximately 7 pF.

This input capacitance can be used in conjunction with an external R–C circuit for digital signal deskewing, if required. In applications where some of the DAC16's digital inputs are not used, the recommended procedure to turn off one or more inputs is to connect each input line to +5 V as shown in Figure 6.

APPLICATIONS

Power Supplies, Bypassing, and Grounding

All precision converter products require careful application of good grounding practices to maintain full-rated performance. As is always the case with analog circuits operating in digital environments, digital noise is prevalent; therefore, special care must be taken to ensure that the DAC16's inherent precision is maintained. This means that particularly good engineering judgment should be exercised when addressing the power supply, grounding, and bypassing issues using the DAC16.

The DAC16 was designed to operate from +5 V and −15 V supplies. The +5 V supply primarily powers the digital portion of the DAC16 and can consume 20 mA, maximum. Although very little +5 V supply current is used by the reference amplifier, large amounts of digital noise present on the +5 V supply can introduce analog errors. It is therefore very important that the +5 V supply be well filtered and regulated. The −15 V supply provides most of the current for the reference amplifier and all of the current for the internal DAC. Although the maximum current in this supply is 10 mA, it must provide a low impedance path for the DAC switch currents. Therefore, it too must be well filtered and regulated.

The DAC16 includes two ground connections in order to minimize system accuracy degradation arising from grounding errors. The two ground pins are designated DGND (Pin 2) and AGND (Pin 22). The DGND pin is the return for the digital circuit sections of the DAC and serves as their input threshold reference point. Thus, DGND should be connected to the same ground as the circuitry that drives the digital inputs.

Pin 22, AGND, serves as the reference point for the 9-bit lower-order DAC as well as the common for the reference amplifier, REFGND (Pin 21). This pin should also serve as the reference point for all analog circuitry associated with the DAC16. Therefore, to minimize any errors, it is recommended that AGND connection on the DAC16 be connected to a high quality analog ground. If the system contains any analog signal path carrying a significant amount of current, then that path should have its own return connection to Pin 22.

It is often advisable to maintain separate analog and digital grounds throughout a complete system, tying them common to one place only. If the common tie point is remote and an accidental disconnection of that one common tie point were to occur due to card removal with power on, a large differential voltage between the two commons could develop. To protect devices that interface to both digital and analog parts of the system, such as the DAC16, it is recommended that common ground tie points be provided at each such device. If only one system ground can be connected directly to the DAC16, it is recommended that the analog common be used. If the system's AGND has suitable low impedance, then the digital signal currents flowing in it should

not seriously affect the ground noise. The amount of digital noise introduced by connecting the two grounds together at the device will not adversely affect system performance due to loss of digital noise immunity.

Generous bypassing of the DAC's supplies goes a long way in reducing supply-line induced errors. Even with well-filtered, well-regulated supplies, local bypassing consisting of 10 μF tantalum electrolytic shunted by a 0.1 μF ceramic is recommended. The decoupling capacitors should be connected between the DAC's supply pins (Pin 3 for +5 V, Pin 20 for −15 V) and the analog ground (Pin 22). Figure 19 shows how the DGND, AGND, and bypass connections should be made to the DAC16.

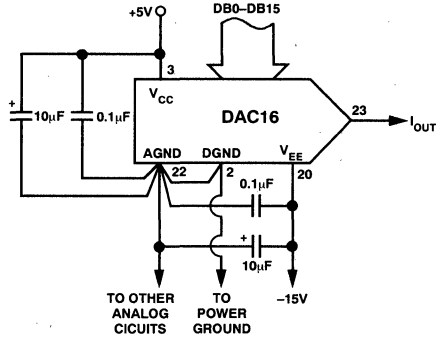

Figure 19. Recommended Grounding and Bypassing Scheme for the DAC16

Using the Right Capacitors

Probably the most important external components associated with high speed design are the capacitors used to bypass the power supplies and to provide compensation. Both selection and placement of these capacitors can be critical and, to a large extent, dependent upon the specifics of the system configuration. The dominant consideration in selection of bypass and compensation capacitors for the DAC16 is minimization of series resistance and inductance. Many capacitors begin to look inductive at 20 MHz and above—the very frequencies where rejection of interference is needed. Ceramic and film-type capacitors generally feature lower series inductance than tantalum or electrolytic types. A few general rules are of universal use when approaching the issue of compensation or bypassing.

Bypass capacitors should be installed on the printed circuit board with the shortest possible leads consistent with reliable construction. This helps to minimize series inductance in the leads. Chip capacitors are optimal in this respect. Where illustrated in the applications section, large tantalum electrolytic capacitors are shunted by low self-inductance ceramic capacitors. This technique reduces the self-resonance of the electrolytics while shifting the resonant frequency of the ceramics out-of-band.

Some series inductance between the DAC supply pins and the power supply plane often helps to filter out high frequency power supply noise. This inductance can be generated using a small ferrite bead as shown in Figure 20.

Reference Amplifier Considerations

The reference input current buffer is a high performance amplifier optimized for high accuracy and linearity. The design of the reference amplifier ensures fast settling times by tightly controlling the node common to all the current sources internal to the DAC with an external compensation capacitor (C_{COMP}). Since the primary design goal of the DAC16 is to achieve 16-bit performance, proper operation of the reference amplifier requires a

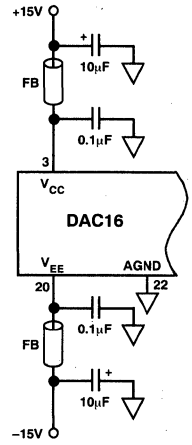

Figure 20. Using a Ferrite Bead as a High Frequency Filter

47 μF tantalum electrolytic capacitor shunted by a 0.1 μF ceramic capacitor, as shown in Figure 21. Increasing the capacitance at this node above the recommended values does not further reduce the analog transition current noise spikes at the output of the reference amplifier. Reducing the value of compensation, however, is not recommended as DAC linearity will degrade as a result. In most systems, the V_{EE} supply offers sufficiently low impedance to maintain a quiet return point for the reference amplifier. If this is not the case, the AGND point can also be used for the compensation capacitor return, as shown in Figure 21.

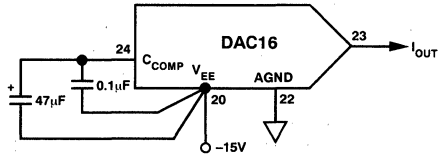

Figure 21a. Recommended Compensation Scheme to V_{EE}

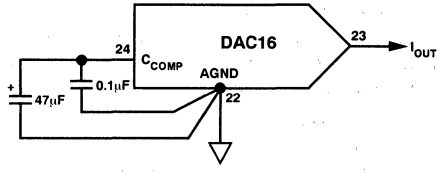

Figure 21b. Recommended Compensation Scheme to AGND

In applications where 16-bit multiplying performance is required, the DAC16 might appear to be a viable solution. However, the compensation capacitor network would have to be removed in these applications. The DAC16's reference amplifier was specifically designed for low frequency operation, with a compensation capacitor network. In fact, this network serves not only as a charge reservoir for the DAC's internal current sources

but also as a wideband noise filter for the reference amplifier. Completely removing the compensation network would introduce large linearity errors, reference amplifier instability, wideband reference amplifier noise, and poor settling time.

Because the DAC exhibits an internal current scaling factor of eight times (8×), the reference amplifier requires only 500 μA input current from the user-supplied precision reference for a 4 mA full-scale output current. In applications that do not require such high output currents, good accuracy can be achieved with input reference currents in the range of 350 μA $\leq I_{REF} \leq$ 625 μA. The best signal-to-noise ratios, of course, will be achieved with a 625 μA reference current which yields a maximum 5 mA output current. Figure 22 illustrates how to form the reference input current with a REF02 and a 10 kΩ precision resistor.

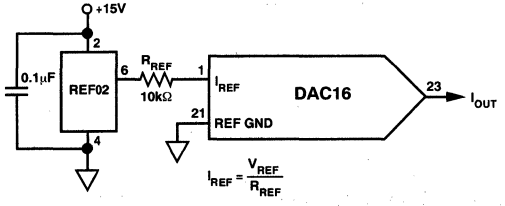

Figure 22. Generating the DAC16's Reference Input Current

Reducing Voltage Reference Noise

In data converters of 16-bit and greater resolution, noise is of critical importance. Surprisingly, the integrated voltage reference circuit used may contribute the dominant share of a system's noise floor, thereby degrading system dynamic range and signal-to-noise ratio. To maximize system dynamic range and SNR, all external noise contributions should be effectively much less than 1/2 LSB. For example, in a 5 V DAC16 application, one LSB is equivalent to 76 μV. This means that the total wideband noise contribution due to a voltage reference and all other sources should be less than 38 μV rms. These noise levels are not easy targets to hit with standard off-the-shelf reference devices. For example, commercially available references might exhibit 5 μV rms noise from 0.1 Hz to 10 Hz; but, over a 100 kHz bandwidth, its 300 μV rms of noise can easily swamp out a 16-bit system. Such noisy behavior can degrade a DAC's effective resolution by increasing its differential nonlinearity which, in turn, can lead to nonmonotonic behavior or analog errors.

The easiest way to reduce noise in the reference circuit is to band-limit its noise before feeding it to the converter. In the case of the DAC16, the reference is not a voltage, but a current. Illustrated in Figure 23 is a simple way of band-limiting

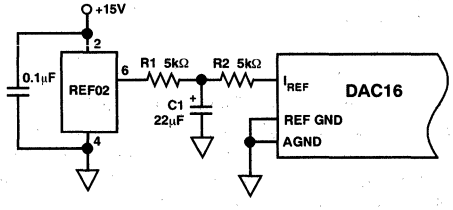

Figure 23. Filtering a Reference's Wideband Noise

voltage reference noise by splitting R_{REF} into two equal resistors and bypassing the common node with a capacitor. To minimize thermally induced errors, R1 and R2 must be electrically and thermally well-matched. Thin-film resistor networks work well here. In this circuit, the parallel combination of R1 and R2 forms a 3 Hz low pass filter with C1. The only noise source that remains is the thermal noise of R2 which can be a significantly lower noise generator than the voltage reference.

Input Coding

The unipolar digital input coding of the DAC16 employs negative logic to control the output current; that is, an all zero input code (0000_H) yields an output current 1 LSB below full scale. Conversely, an all 1s input code ($FFFF_H$) yields a zero analog current output. An expression for the DAC16's transfer equation can be expressed by:

$$I_{OUT} = 8 \times I_{REF} \times \left[\frac{65{,}535 - Digital\ Code}{65{,}536}\right]$$

Table II provides the relationship between the digital input codes and the output current of the DAC16.

Table II. Unipolar Code Table

Digital Input Word (Hex)	DAC16 Output Current I_{OUT}	Comment
0000	$8 \times (2^{16} - 1)/2^{16} \times I_{REF}$	Full Scale
7FFE	$8 \times (2^{15} + 1)/2^{16} \times I_{REF}$	Midscale + 1 LSB
7FFF	$8 \times (2^{15}/2^{16}) \times I_{REF}$	Midscale
8000	$8 \times (2^{15} - 1)/2^{16} \times I_{REF}$	Midscale − 1 LSB
FFFF	0	Zero Scale

Since the DAC16 exhibits a small output voltage compliance on the order of a few millivolts, a high accuracy operational amplifier must be used to convert the DAC's output current to a voltage. Refer to the section on selecting operation amplifiers for the DAC16. The circuit shown in Figure 24 illustrates a unipolar output configuration. In symbolic form, the transfer equation for this circuit can be expressed by:

$$V_O = R3 \times 8 \times I_{REF} \left[\frac{65{,}535 - Digital\ Code}{65{,}536}\right]$$

In this example, the reference input current was set to 500 μA which produces a full-scale output current of 4 mA − 1 LSB. The DAC's output current was scaled by R3, a 1.25 kΩ resistor, to produce a 5 V full-scale output voltage. Bear in mind that to ensure the highest possible accuracy, matched thin-film resistor networks are almost a necessity, not an option. The resistors used in the circuit must have close tolerance and tight thermal tracking. Table III illustrates the relationship between the input digital code and the circuit's output voltage for the component values shown.

Table III. Unipolar Output Voltage vs. Digital Input Code

Digital Input Word (Hex)	Decimal Number in in DAC Decoder	Analog Output Voltage (V)
0000	65,535	4.999924
7FFE	32,769	2.500076
7FFF	32,768	2.500000
8000	32,767	2.499924
FFFF	0	0

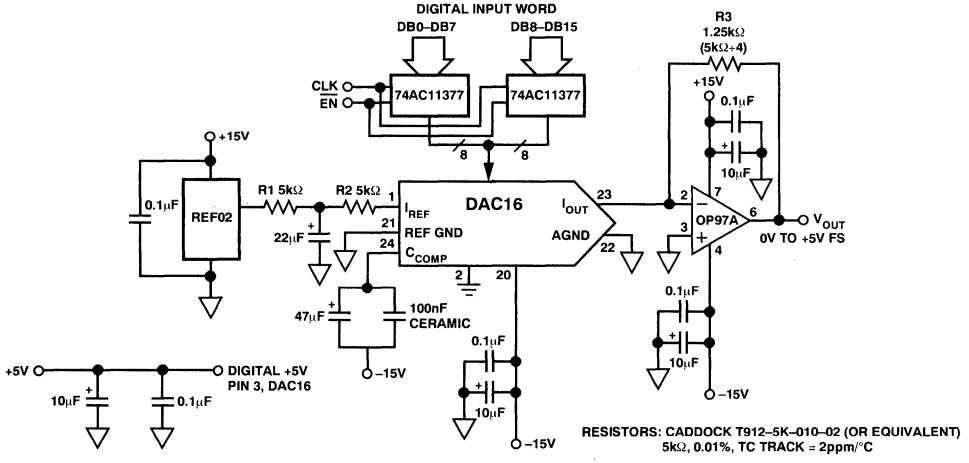

Figure 24. Unipolar Circuit Configuration

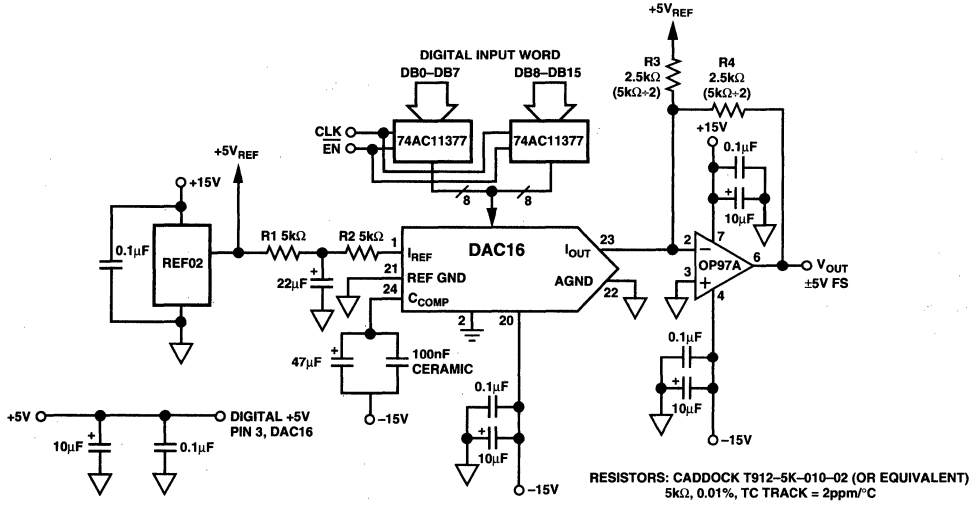

Figure 25. Bipolar Circuit Configuration

Bipolar Configuration

For applications that require a bipolar output voltage, the circuit in Figure 24 can be modified slightly by adding a resistor from the reference to the inverting sum node of the output amplifier to level shift the output signal. The transfer equation for the circuit now becomes:

$$V_O = R4 \times 8 \times I_{REF}\left[\frac{65{,}535 - Digital\ Code}{65{,}536}\right] - V_{REF} \times \left(\frac{R4}{R3}\right)$$

The circuit has the form shown in Figure 25, and Table IV provides the relationship between the digital input code and the circuit's output voltage for the component values shown.

Table IV. Bipolar Output Operation vs. Digital Input Code

Digital Input Word (Hex)	Decimal Number in DAC Decoder	Analog Output Voltage (V)
0000	65,535	4.999848
7FFE	32,769	152E-6
7FFF	32,768	0
8000	32,767	−152E-6
FFFF	0	−5.00000

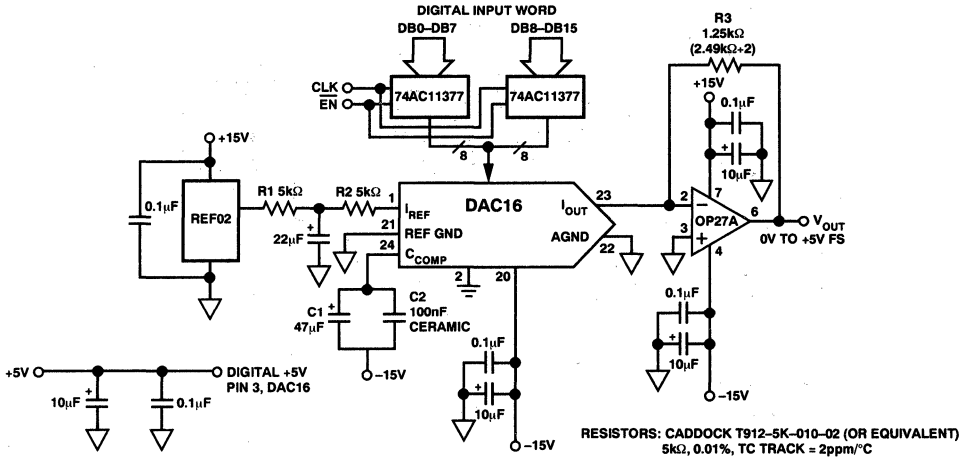

Figure 26. DAC16 Noise Measurement Test Circuit

DAC16 Noise Performance

The novel architecture employed in the DAC16 yields very low wideband noise. Figure 26 illustrates the circuit configuration for evaluating the DAC16's noise performance. An OP27 is used as the DAC16's output I–V converter which is configured to produce a 5 V full-scale output voltage. The output of the OP27 was then capacitively coupled to an OP37 stage configured in a gain of 101. Note that the techniques for reducing wideband noise of the voltage reference and the DAC's internal reference amplifier were used. As a result of these techniques, the DAC16 exhibited a full-scale output noise spectral density of 31 $pA/\sqrt{Hz}$ at 1 kHz.

Digital Feedthrough and Data Skew

The DAC16 features a compound DAC architecture where the 5 most significant bits utilize 31 identical, segmented current sources to obtain optimal high speed settling at major code transitions. Although every effort has been made to equalize the speeds at which the DAC switches operate, there exists finite skew in the MSB DAC switches.

As with any converter product, a high speed digital-to-analog converter is forced to exist on the frontier between the noisy environment of high speed digital logic and the sensitive analog domain. The problems of this interface are particularly acute when demands of high speed (greater than 10 MHz switching times) and high precision are combined. No amount of design effort can perfectly isolate the analog portions of a DAC from the spectral components of a digital input signal with a 2 ns rise time. Inevitably, once this digital signal is brought onto the chip, some of its higher frequency components will find their way to the sensitive analog nodes, producing a digital feedthrough glitch. To minimize the exposure to this effect, the DAC16 was designed to omit intentionally the on-board latches that are usually included in many slower DACs. This not only reduces the overall level of digital activity on chip, it also avoids bringing a latch clock pulse onto the IC, whose opposite edge inevitably produces a substantial glitch, even when the DAC is not supposed to be changing codes.

The DAC16 uses each digital input line to switch each current segment in the DAC between the output diode-connected transistor and the logic control transistor. If the input bits are not changed simultaneously, or if the different DAC bits switch at different speeds, then the DAC output current will momentarily take on some incorrect value. This effect is particularly troublesome at the "carry points," where the DAC output is to change by only one LSB, but several of the larger current sources must be switched to realize this change. Data skew can allow the DAC output to move a substantial amount towards full scale or zero (depending upon the direction of the skew) when only a small transition is desired. The glitch-sensitive user should be equally diligent about minimizing the data skew at the DAC16's inputs, particularly the five most significant bits. This can be achieved by using the proper logic family and gate to drive the DAC inputs, and keeping the interconnect lines between the latches and the DAC inputs as short and as well matched as possible. Logic families that were empirically determined to operate well with the DAC16 are devices from the 74AC11XXX and 74ACT11XXX advanced CMOS logic families. These devices have been purposely designed with improved layout and tailored rise times for minimizing ground bounce and digital feedthrough.

Deglitching

The output glitch of the DAC16 at the major carry ($7FFE_H$ to $7FFF_H$) is a not-insignificant 360 pA-sec, manifested as a momentary output transition to the negative rail for approximately 200 ns. Due to the inherent low-pass or time-sampled nature of many systems, this behavior in the DAC16 is not noticeable and does not detract from overall performance. Some applications however may prove so sensitive to glitch impulse that reduction by an order of magnitude or more is required. In order to realize low glitch impulses, some sort of sample-and-hold amplifier-based deglitching scheme must be used.

There are high speed SHAs available with specifications sufficient to deglitch the DAC16; however, most are hybrid in topology at costs which can be prohibitive. A high performance, low cost alternative shown in Figure 27 is a discrete SHA utilizing a high speed monolithic op amp and high speed DMOS FET switches.

This SHA circuit uses the inverting integrator structure. A 300 MHz gain-bandwidth product op amp, the AD841, is the heart of this fast SHA. The time constant formed by the 200 Ω resistor and the 100 pF capacitor determines the acquisition time and also band limits the output signal to eliminate slew-induced distortion.

A discrete drive circuit is used to achieve the best performance from the SD5000 quad DMOS switch. This switch-driving cell is composed of MPS571 RF NPN transistors and an MC10124 TTL-to-ECL translator. Using this technique provides both high speed and highly symmetrical drive signals for the SD5000 switches. The switches are arranged in a single-pole, double-throw (SPDT) configuration. The 500 pF "flyback" capacitor is switched to the op amp summing junction during the hold mode to keep switching transients from feeding to the output. This capacitor is grounded during sample mode to minimize its effect on acquisition time.

Careful circuit layout of the high speed SHA section is almost as important as the design itself. Double-sided printed circuit board, a compact layout, and short critical signal paths all ensure best performance.

Op Amp Selection

When selecting the amplifier to be used for the DAC16's I–V converter, there are two main application areas; those requiring high accuracy, and those seeking high speed. In high accuracy applications, three parameters are of prime importance: (1) input offset voltage, V_{OS}; (2) input bias current, $-I_B$; and (3) offset voltage drift, TCV_{OS}. In these applications where 16-bit performance must be maintained with an external reference at +5 V, an op amp's input offset voltage must be less than 15 μV (≈0.1 LSB) with a bias current less than 6 nA. The op amp must also exhibit high open-loop gain to keep the offset voltage below this limit over the specified full-scale output range. Thus, for an maximum output of 5 V, the op amp's open loop gain must be greater than 1300 V/mV.

For low frequency, high accuracy applications, Table IV lists selected compatible operational amplifiers available from Analog Devices. These operational amplifiers satisfy all the above requirements and in most all cases will not require offset voltage nulling.

Table V. Precision Operational Amplifiers for the DAC16

Model	V_{OS}	TCV_{OS}	I_B	A_{VOL}
OP177	10 μV	0.3 μV/°C	2 nA	12000 V/mV
OP77	25 μV	0.6 μV/°C	2.8 nA	2000 V/mV
OP27	25 μV	0.2 μV/°C	80 nA	1500 V/mV
OP97	25 μV	2 μV/°C	0.15 nA	2000 V/mV

In high speed applications where resolution is more important than absolute accuracy, operational amplifiers such as the AD843 offer the requisite settling time. Although these amplifiers are not specified for 16-bit performance, their settling times are two to three times faster than the DAC16 and will introduce negligible error to the overall circuit's settling time. It is possible to estimate the 16-bit settling time of an operational amplifier if its 12-bit settling time is known. Assuming that the op amp can be modeled by a single-pole response, then the ratio of the op amp's 16-bit settling time to its 12-bit settling can be expressed as:

$$\frac{t_S\ (16\text{-}bit)}{t_S\ (12\text{-}bit)} = 1.33$$

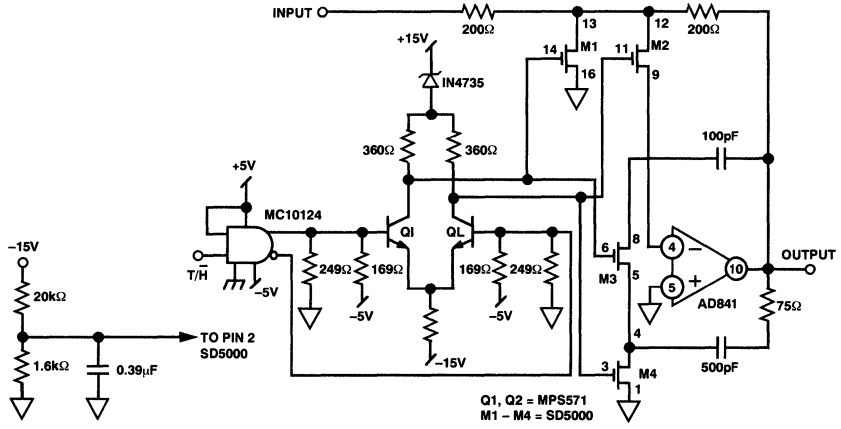

Figure 27. A High Performance Deglitching Circuit

Since many operational amplifier data sheets provide charts illustrating 0.01% settling time versus output voltage step size, all that is required to estimate an op amp's 16-bit settling time is to multiply the 12-bit settling time for the required full-scale voltage by 1.33. The circuit's overall settling time can then be approximated by the root-sum-square method:

$$t_S = \sqrt{(t_{DAC})^2 + (t_{OA})^2}$$

where

t_{DAC} = DAC16's specified full-scale settling time

t_{OA} = Op amp full-scale settling time

As a design aid, Table VI illustrates a high speed operational amplifier selector guide for devices compatible with the DAC16 for high speed applications. All these devices exhibit the requisite settling time, input offset voltage, and input bias current consistent with maximum performance.

Table VI. High Speed Operational Amplifiers for the DAC16

Model	t_S to %	V_{OS}	TCV_{OS}	I_B	A_{VOL}
OP467	200 ns −0.01	0.5 mV	3.5 μV/°C	0.5 μA	20 V/mV
AD817	70 ns −0.01	2 mV	10 μV/°C	6.6 μA	6 V/mV
AD829	90 ns −0.1	0.5 mV	0.3 μV/°C	7 μA	100 V/mV
AD841	110 ns −0.01	1 mV	35 μV/°C	5 μA	45 V/mV
AD843	135 ns −0.01	1 mV	12 μV/°C	0.001 μA	25 V/mV
AD845	350 ns −0.01	0.25 mV	5 μV/°C	0.001 μA	500 V/mV
AD847	120 ns −0.01	1 mV	15 μV/°C	5 μA	5.5 V/mV

In using high speed op amps, the output capacitance of the DAC16 appears across the inputs of the op amp where it and the op amp's input capacitance will set an additional pole in the op amp's loop gain response. The pole is formed with the feedback resistance and the output resistance of the DAC. This additional pole may adversely affect the transient response of the circuit due to the added phase shift. Placing a small capacitor across the feedback resistance, as shown in Figure 28, compensates for the additional pole. The value of the capacitor can be determined by setting $R_{FB}C_{FB} = R_O (C_O + C_{IN})$ and should be adjusted for optimum transient response.

The choice of amplifier depends entirely on the required system accuracy, the required temperature range, and the operating frequency.

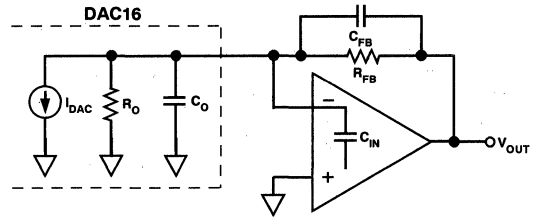

Figure 28. Compensating for the Feedback Pole

GENERAL DESCRIPTION

The DAC-312 series of 12-bit multiplying digital-to-analog converters provide high speed with guaranteed performance to 0.012% differential nonlinearity over the full commercial operating temperature range.

Based on the segmented design approach pioneered by PMI with the COMDAC® line of data converters, the DAC-312 combines a 9-bit master D/A converter with a 3-bit (MSB's) segment generator to form an accurate 12-bit D/A converter at low cost. This technique guarantees a very uniform step size (up to ±1/2 LSB from the ideal), monotonicity to 12 bits and integral nonlinearity to 0.05% at its differential current outputs. In order to provide the same performance with a 12-bit R-2R ladder design, an integral nonlinearity over temperature of 1/2 LSB (0.012%) would be required.

The 250ns settling time with low glitch energy and low power consumption are achieved by careful attention to the circuit design and stringent process controls. Direct interface with all popular logic families is achieved through the logic threshold terminal.

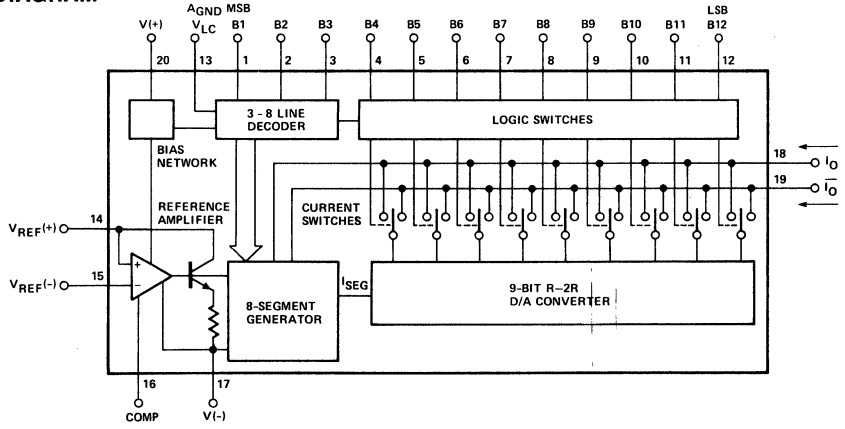
FUNCTIONAL DIAGRAM



This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

High compliance and low drift characteristics (as low as 10ppm/°C) are also features of the DAC-312 along with an excellent power supply rejection ratio of ±.001% FS/%ΔV. Operating over a power supply range of +5/−11V to ±18V the device consumes 225mW at the lower supply voltages with an absolute maximum dissipation of 375mW at the higher supply levels.

With their guaranteed specifications, single chip reliability and low cost, the DAC-312 device makes excellent building blocks for A/D converters, data acquisition systems, video display drivers, programmable test equipment and other applications where low power consumption and complete input/output versatility are required.

GENERAL DESCRIPTION

The DAC-8043 is a high accuracy 12-bit CMOS multiplying DAC in a space-saving 8-pin mini-DIP package. Featuring serial data input, double buffering, and excellent analog performance, the DAC-8043 is ideal for applications where PC board space is at a premium. Also, improved linearity and gain error performance permit reduced parts count through the elimination of trimming components. Separate input clock and load-DAC control lines allow full user control of data loading and analog output.

The circuit consists of a 12-bit serial-in, parallel-out shift register, a 12-bit DAC register, a 12-bit CMOS DAC, and control logic. Serial data is clocked into the input register on the rising edge of the CLOCK pulse. When the new data word has been clocked in, it is loaded into the DAC register with the $\overline{LD}$ input pin. Data in the DAC register is converted to an output current by the D/A converter.

The DAC-8043's fast interface timing may reduce timing design considerations while minimizing microprocessor wait states. For applications requiring an asynchronous CLEAR function or more versatile microprocessor interface logic, refer to the PM-7543.

Operating from a single +5V power supply, the DAC-8043 is the ideal low power, small size, high performance solution to many application problems. It is available in plastic and cerdip packages that are compatible with auto-insertion equipment.

GENERAL DESCRIPTION

The DAC-8221 combines two identical 12-bit, multiplying, digital-to-analog converters into a single CMOS chip. This device is electrically similar to DAC-8212 with improved microprocessor interface timing and is packaged in a narrow 0.300" DIP. Monolithic construction offers excellent DAC-to-DAC matching and tracking over the full operating temperature range. The DAC-8221 consists of two thin-film R-2R resistor-ladder networks, two 12-bit data latches, one 12-bit input buffer, and control logic. The DAC-8221 operates on a single supply from +5V to +15V. Maximum power dissipation with 0V and +5V logic levels and a +5V supply is less than 0.5mW. The DAC-8221 is manufactured using PMI's highly-stable, thin-film resistors on an advanced oxide-isolated, silicon-gate, CMOS process. PMI's improved latch-up resistant design eliminates the need for external protective Schottky diodes.

A common 12-bit (TTL/CMOS compatible) input port is used to load a 12-bit-wide word into either of the two DACs. This port, whose data loading is similar to that of a RAM's write cycle, interfaces directly with most 12-bit or wider bus systems. With $\overline{WR}$ and $\overline{CS}$ lines at logic LOW, the input data registers are transparent. This allows direct unbuffered data to flow directly to the DAC output selected by $\overline{DAC\ A}$/DAC B control input. For applications requiring double-buffering, see the DAC-8222.

PACKAGE TYPE	Θ_{JA} (NOTE 1)	Θ_{JC}	UNITS
24-Pin Hermetic DIP (W)	69	10	°C/W
24-Pin Plastic DIP (P)	62	32	°C/W
24-Pin SOL (S)	72	24	°C/W

NOTE:
1. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP, and P-DIP packages; Θ_{JA} is specified for device soldered to printed circuit board for SOL package.

CAUTION:
1. Do no apply voltages higher than V_{DD} or less than GND potential on any terminal except V_{REF} and R_{FB}.
2. The digital control inputs are zener-protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam at all times until ready to use.
3. Do not insert this device into powered sockets; remove power before insertion or removal.
4. Use proper anti-static handling procedures.
5. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied.

Dual 12-Bit Double-Buffered Multiplying CMOS D/A Converter

DAC8222

3

FEATURES

- Two Matched 12-Bit DACs on One Chip
- Direct Parallel Load of All 12 Bits for High Data Throughput
- Double-Buffered Digital Inputs
- 12-Bit Endpont Linearity (±1/2 LSB) Over Temperature
- +5V to +15V Single Supply Operation
- DACs Matched to 1% Max
- Four-Quadrant Multiplication
- Improved ESD Resistance
- Packaged in a Narrow 0.3" 24-Pin DIP and 0.3" 24-Pin SOL package
- Available in Die Form

APPLICATIONS

- Automatic Test Equipment
- Robotics/Process Control/Automation
- Digital Gain/Attenuation Control
- Ideal for Battery-Operated Equipment

GENERAL DESCRIPTION

The DAC-8222 is a dual 12-bit, double-buffered, CMOS digital-to-analog converter. It has a 12-bit wide data port that allows a 12-bit word to be loaded directly. This achieves faster throughput time in stand-alone systems or when interfacing to a 16-bit processor. A common 12-bit input TTL/CMOS compatible data port is used to load the 12-bit word into either of the two DACs. This port, whose data loading is similar to that of a RAM's write cycle, interfaces directly with most 12-bit and 16-bit bus systems. (See PMI's DAC-8248 for a complete 8-bit data bus interface product.) A common bus allows the DAC-8222 to be packaged in a narrow 24-pin 0.3" DIP and save PCB space.

PIN CONNECTIONS

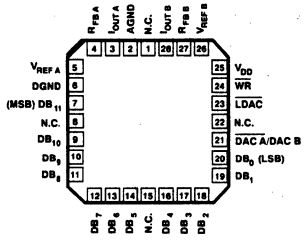
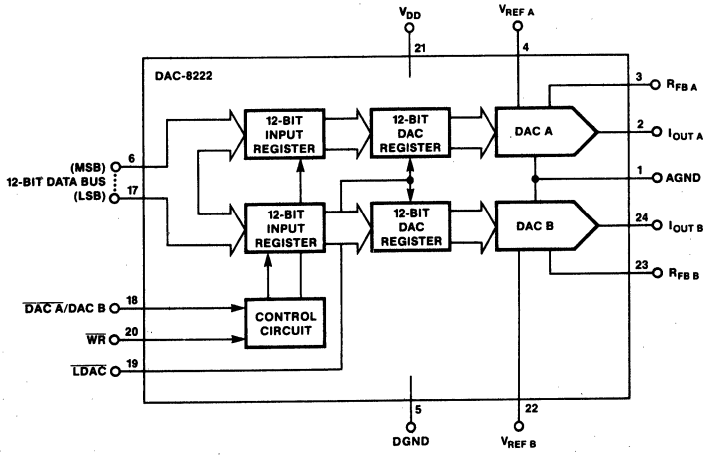
24-PIN EPOXY DIP (P-Suffix)

24-PIN SOL (S-Suffix)



28-CONTACT LCC (TC-Suffix)

FUNCTIONAL DIAGRAM



This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

The DAC is controlled with two signals, $\overline{WR}$ and $\overline{LDAC}$. With logic low at these inputs, the DAC registers become transparent. This allows direct unbuffered data to flow directly to either DAC output selected by $\overline{DAC\ A/DAC\ B}$. Also, the DAC's double-buffered digital inputs will allow both DACs to be updated simultaneously.

DAC-8222's monolithic construction offers excellent DAC-to-DAC matching and tracking over the full operating temperature range. The chip consists of two thin-film R-2R resistor ladder networks, four 12-bit registers, and DAC control logic circuitry. The device has separate reference-input and feedback resistors for each DAC and operates on a single supply from +5V to +15V. Maximum power dissipation at +5V using zero or V_{DD} logic levels is less than 0.5mW.

The DAC-8222 is manufactured with PMI's highly stable thin-film resistors on an advanced oxide-isolated, silicon-gate, CMOS technology. PMI's improved latch-up resistant design eliminates the need for external protective Schottky diodes.

Dual 8-Bit CMOS D/A Converter with Voltage Output

DAC8228

FEATURES

- Two 8-Bit Voltage Out DACs in a Single Chip
- Fits 7528/7628 Sockets
- Adjustment Free Internal CMOS Op Amps
- Single +12V to +15V Operation
- TTL Compatible Over Full V_{DD} Range
- Fast Interface Timing ..... T_{WR} = 50ns
- Improved Resistance to ESD
- Available in Small Outline Package
- CerDIP and Epoxy Packages Come in the Extended Industrial Temperature Range of –40°C to +85°C
- Available in Die Form

APPLICATIONS

- Disk Drive Systems
- Automatic Test Equipment
- Process/Industrial Controls
- Energy Controls
- Programmable Instrumentation
- Multi-Channel Microprocessor-Controlled Systems
- Servo Control Systems

GENERAL DESCRIPTION

The DAC-8228 is a dual 8-bit, voltage output, CMOS, D/A converter in a single chip. It was designed to drop into AD7528/7628 sockets eliminating two external op amps in applications such as hard disk drives. These applications generally operate the AD7528/7628 with zero volts applied to V_{REF} and offset AGND to +2.5 or +5 volts. The DAC-8228 is tested under both these conditions.

The DAC-8228 can also be used in those applications requiring a unipolar output voltage. It can deliver an output voltage between 0V and +10V with V_{DD} = +14V (maximum output voltage is V_{DD} –4V). The DAC-8228's reference input can accept a negative voltage from 0V to –10V (the DAC's internal unity-gain inverting amplifier inverts the input signal). Choose the DAC-8229 for bipolar operation.

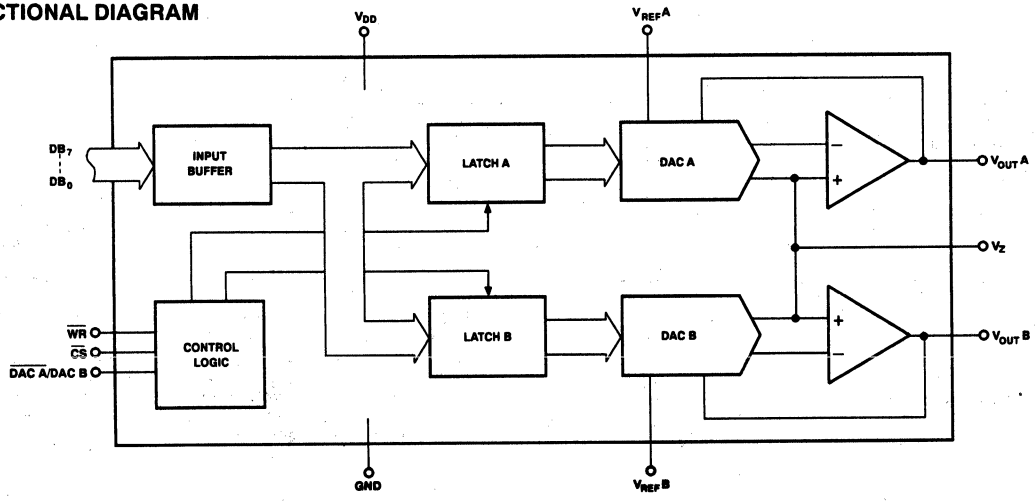
FUNCTIONAL DIAGRAM



This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

GENERAL DESCRIPTION *Continued*

The DAC-8228 offers CerDIP and plastic packaged devices in the extended industrial temperature range of –40°C to +85°C. Applications requiring the military temperature range should use the DAC-8229. To make the DAC-8229 pin and functionally compatible with the DAC-8228, AGND A and AGND B should be tied together to function as V_Z, and V_{SS} connected to GND.

The DAC-8228 consists of two CMOS voltage output amplifiers, two high-accuracy R-2R resistor ladder networks, interface control logic, and two 8-bit registers. An internal regulator maintains TTL logic compatibility and fast microprocessor interface timing over the full V_{DD} range.

The DAC-8228 dissipates only 90mW in the space saving 20-pin 0.3" DIP or the 20-lead SO surface mount package. Its compact size, low power, and economical cost per channel, makes it attractive for applications requiring multiple D/A converters without sacrificing circuit-board space. Reduced parts count also improves system reliability.

Using PMI's advanced oxide-isolated, silicon-gate CMOS process, coupled with its highly-stable thin-film resistor ladder, allows the DAC-8228 to offer superior matching and temperature tracking between DACs.

ABSOLUTE MAXIMUM RATINGS

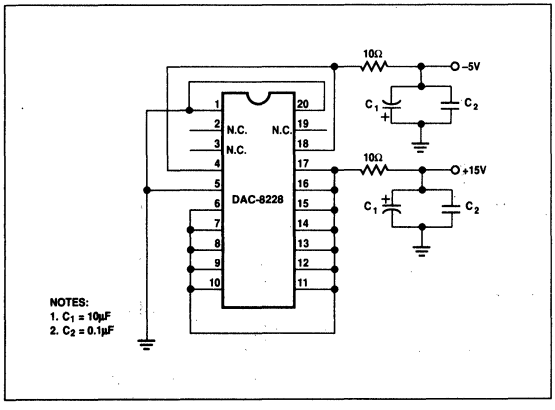
BURN-IN CIRCUIT



Dual 8-Bit CMOS D/A Converter with Voltage Output

DAC8229

FEATURES

- Two 8-Bit DACs In A Single Chip
- Adjustment-Free Internal CMOS Amplifiers
- Single or Dual Supply Operation
- TTL Compatible Over Full V_{DD} Range
- 5 Microsecond Settling Time
- Fast Interface Timing ..... t_{WR} = 50ns
- Improved Resistance to ESD
- Fits AD/PM-7528 And AD/PM-7628 Sockets
- Available In Small Outline Package
- –40°C to +85°C for the Extended Industrial Temperature Range
- Available In Die Form

APPLICATIONS

- Automatic Test Equipment
- Process/Industrial Controls
- Energy Controls
- Programmable Instrumentation
- Disk Drive Systems
- Multi-Channel Microprocessor-Controlled Systems

GENERAL DESCRIPTION

The DAC-8229 is a dual 8-bit, voltage output, multiplying CMOS D/A converter. Its reference input accepts a ±2.5V signal, inverts and delivers it to the output with an internal amplifier. It can also accept –10V at V_{REF} with a corresponding +10V output (the maximum positive input signal that it can accept is +2.5V).

The DAC-8229 was designed to operate with dual supplies; however, it can be operated with a single supply by connecting

GENERAL DESCRIPTION *Continued*

V_{SS}, AGND A, and AGND B to ground. Its operating characteristics will then be similar to that of the DAC-8228 (whose pin-out allows it to drop into the AD/PM-7528 and AD/PM-7628 sockets).

An internal regulator provides TTL logic compatibility and fast microprocessor interface timing over the full V_{DD} range. Also, each DAC input latch is addressable for easy microprocessor interfacing.

The DAC-8229 dissipates less than 109mW in the space-saving 20-pin 0.3" DIP or the 20-lead SO surface-mount package. Its compact size, low power, and economical cost per channel, make it attractive for applications requiring multiple D/A converters without sacrificing circuit-board space. Reduced parts count also improves system reliability.

PMI's advanced oxide-isolated, silicon-gate CMOS process, coupled with PMI's highly-stable thin-film R-2R resistor ladder, offers superior matching and temperature tracking between DACs.

The DAC-8229 offers cerdip or epoxy packaged devices in the extended industrial temperature range of –40°C to +85°C.

Dual 12-Bit (8-Bit Byte) Double-Buffered CMOS D/A Converter

DAC8248

FEATURES

- Two Matched 12-Bit DACs on One Chip
- 12-Bit Resolution with an 8-Bit Data Bus
- Direct Interface with 8-Bit Microprocessors
- Double-Buffered Digital Inputs
- $\overline{\text{RESET}}$ to Zero Pin
- 12-Bit Endpont Linearity (±1/2 LSB) Over Temperature
- +5V to +15V Single Supply Operation
- Latch-Up Resistant
- Improved ESD Resistance
- Packaged in a Narrow 0.3" 24-Pin DIP and 0.3" 24-Pin SOL package
- Available in Die Form

APPLICATIONS

- Multi-Channel Microprocessor-Controlled Systems
- Robotics/Process Control/Automation
- Automatic Test Equipment
- Programmable Attenuator, Power Supplies, Window Comparators
- Instrumentation Equipment
- Battery Operated Equipment

GENERAL DESCRIPTION

The DAC-8248 is a dual 12-bit, double-buffered, CMOS digital-to-analog converter. It has an 8-bit wide input data port that interfaces directly with 8-bit microprocessors. It loads a 12-bit word in two bytes using a single control; it can accept either a least significant byte or most significant byte first. For designs with a 12-bit or 16-bit wide data path, choose the DAC-8222 or DAC-8221.

The DAC-8248's double-buffered digital inputs allow both DAC's analog output to be updated simultaneously. This is particularly useful in multiple DAC systems where a common $\overline{\text{LDAC}}$ signal updates all DACs at the same time. A single $\overline{\text{RESET}}$ pin resets both outputs to zero.

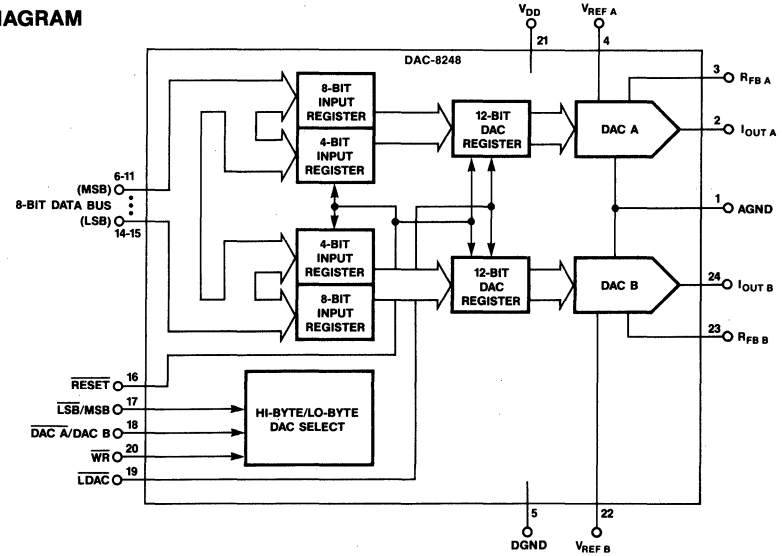
FUNCTIONAL DIAGRAM



This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

The DAC-8248's monolithic construction offers excellent DAC-to-DAC matching and tracking over the full operating temperature range. The DAC consists of two thin-film R-2R resistor ladder networks, two 12-bit, two 8-bit, and two 4-bit data registers, and control logic circuitry. Separate reference input and feedback resistors are provided for each DAC. The DAC-8248 operates on a single supply from +5V to +15V, and it dissipates less than 0.5mW at +5V (using zero or V_{DD} logic levels). The device is packaged in a space-saving 0.3", 24-pin DIP.

The DAC-8248 is manufactured with PMI's highly-stable thin-film resistors on an advanced oxide-isolated, silicon-gate, CMOS technology. PMI's improved latch-up resistant design eliminates the need for external protective Schottky diodes.

PIN CONNECTIONS

24-Pin Hermetic DIP (W)	69	10	°C/W
24-Pin Plastic DIP (P)	62	32	°C/W
24-Pin SOL (S)	72	24	°C/W

NOTE:
1. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP and P-DIP packages; Θ_{JA} is specified for device soldered to printed circuit board for SOL package.

CAUTION:
1. Do no apply voltages higher than V_{DD} or less than GND potential on any terminal except V_{REF} and R_{FB}.
2. The digital control inputs are zener-protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam at all times until ready to use.
3. Do not insert this device into powered sockets; remove power before insertion or removal.
4. Use proper anti-static handling procedures.
5. Devices can suffer permanent damage and/or reliability degradation if stressed above the limits listed under Absolute Maximum Ratings for extended periods. This is a stress rating only and functional operation at or above this specification is not implied.

ELECTRICAL CHARACTERISTICS at V_{DD} = +5V or +15V; $V_{REF\ A} = V_{REF\ B}$ = +10V; $V_{OUT\ A} = V_{OUT\ B}$ = 0V; AGND = DGND = 0V; T_A = Full Temp Range specified in Absolute Maximum Ratings; unless otherwise noted. Specifications apply for DAC A and DAC B.

DAC8408

FEATURES

- **Four DACs in a 28 Pin, 0.6 Inch Wide DIP or 28 Pin JEDEC Plastic Chip Carrier**
- **±1/4 LSB End-Point Linearity**
- **Guaranteed Monotonic**
- **DACs Matched to Within 1%**
- **Microprocessor Compatible**
- **Read/Write Capability (with Memory)**
- **TTL/CMOS Compatible**
- **Four-Quadrant Multiplication**
- **Single-Supply Operation (+5V)**
- **Low Power Consumption**
- **Latch-Up Resistant**
- **Available in Die Form**

APPLICATIONS

- **Voltage Set Points in Automatic Test Equipment**
- **Systems Requiring Data Access for Self-Diagnostics**
- **Industrial Automation**
- **Multi-Channel Microprocessor-Controlled Systems**
- **Digitally Controlled Op Amp Offset Adjustment**
- **Process Control**
- **Digital Attenuators**

GENERAL DESCRIPTION

The DAC-8408 is a monolithic quad 8-bit multiplying digital-to-analog CMOS converter. Each DAC has its own reference input, feedback resistor, and on-board data latches that feature read/write capability. The readback function serves as memory for those systems requiring self-diagnostics.

A common 8-bit TTL/CMOS compatible input port is used to load data into any of the four DAC data-latches. Control lines $\overline{DS1}$, $\overline{DS2}$, and A/$\overline{B}$ determine which DAC will accept data. Data loading is similar to that of a RAM's write cycle. Data can be read back onto the same data bus with control line R/$\overline{W}$. The DAC-8408 is bus compatible with most 8-bit microprocessors, including the 6800, 8080, 8085, and Z80. The DAC-8408 operates on a single +5 volt supply and dissipates less than 20mW. The DAC-8408 is manufactured using PMI's highly stable, thin-film resistors on an advanced oxide-isolated, silicon-gate, CMOS process. PMI's improved latch-up resistant design eliminates the need for external protective Schottky diodes.

PACKAGE TYPE	Θ_{JA} (Note 1)	Θ_{JC}	UNITS
28-Pin Hermetic DIP (T)	55	10	°C/W
28-Pin Plastic DIP (P)	53	27	°C/W
28-Pin SOL (S)	68	23	°C/W
28-Contact PLCC (PC)	66	29	°C/W

NOTE:
1. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP and P-DIP packages; Θ_{JA} is specified for device soldered to printed circuit board for SOL and PLCC packages.

CAUTION:
1. Do not apply voltages higher than V_{DD} + 0.3V or less than –0.3V potential on any terminal except V_{REF} and R_{FB}.
2. The digital control inputs are diode-protected; however, permanent damage may occur on unconnected inputs from high-energy electrostatic fields. Keep in conductive foam at all times until ready to use.
3. Use proper anti-static handling procedures.
4. Absolute Maximum Ratings apply to both packaged devices and DICE. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device.

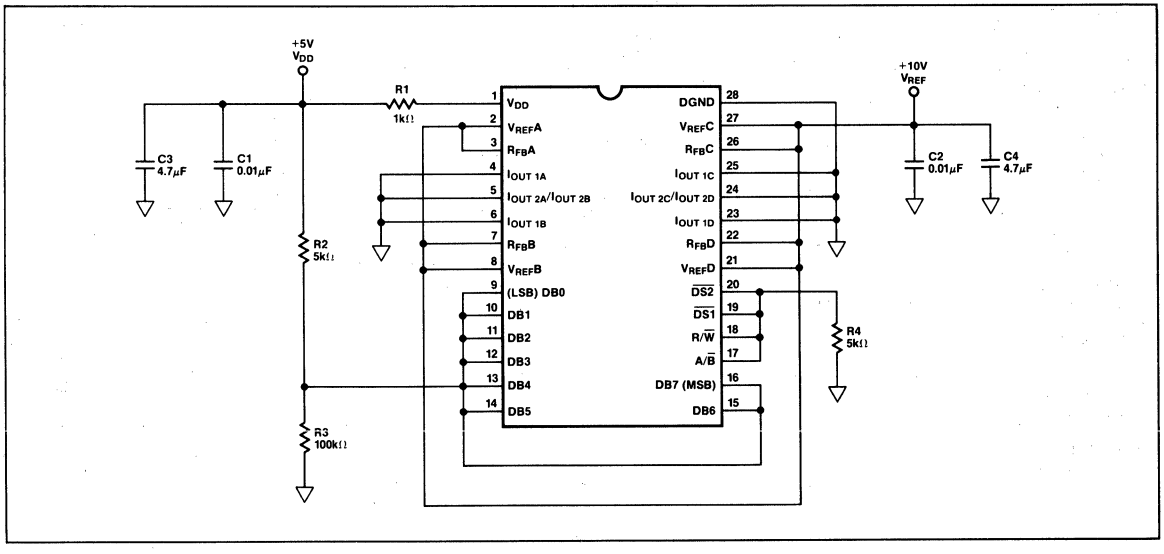
NOTES:
1. This is an end-point linearity specification.
2. Guaranteed to be monotonic over the full operating temperature range.
3. ppm/°C of FSR (FSR = Full Scale Range = V_{REF} – 1 LSB.)
4. Input Resistance Temperature Coefficient = +300ppm/°C.
5. Logic Inputs are MOS gates. Typical input current at +25°C is less than 10nA.
6. Guaranteed by design.
7. From Digital Input to 90% of final analog output current.
8. All Digital Inputs "0" or V_{DD}.
9. All Digital Inputs V_{IH} or V_{IL}.
10. See Timing Diagram.
11. Digital Inputs = 0V to V_{DD} or V_{DD} to 0V.
12. Extrapolated: t_s (1/2 LSB) = t_{pD} + 6.2τ where τ = the measured first time constant of the final RC decay.
13. All Digital Inputs = 0V; V_{REF} = +10V.

BURN-IN CIRCUIT



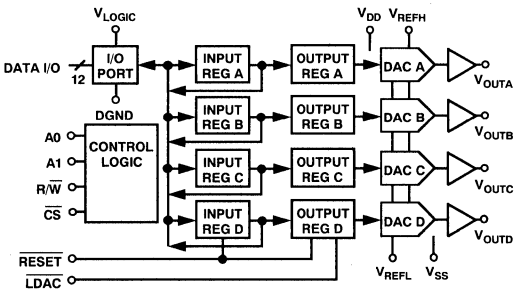
Quad, 12-Bit DAC Voltage Output with Readback

DAC8412/DAC8413

FEATURES
+5 to ±15 Volt Operation
Unipolar or Bipolar Operation
True Voltage Output
Double-Buffered Inputs
Reset to Min or Center Scale
Fast Bus Access Time
Readback

APPLICATIONS
Automatic Test Equipment
Digitally Controlled Calibration
Servo Controls
Process Control Equipment

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The DAC-8412 and DAC-8413 are quad, 12-bit, voltage output DACs with readback capability. Built using a complementary BiCMOS process, these monolithic DACs offer the user very high package density.

Output voltage swing is set by the two reference inputs V_{REFH} and V_{REFL}. By setting the V_{REFL} input to 0 volts and V_{REFH} to a positive voltage, the DAC will provide a unipolar positive output range. A similar configuration with V_{REFH} at 0 volts and V_{REFL} at a negative voltage will provide a unipolar negative output range. Bipolar outputs are configured by connecting both V_{REFH} and V_{REFL} to nonzero voltages. This method of setting output voltage range has advantages over other bipolar offsetting methods because it is not dependent on internal and external resistors with different temperature coefficients.

Digital controls allow the user to load or read back data from any DAC, load any DAC and transfer data to all DACs at one time.

An active low $\overline{RESET}$ loads all DAC output registers to mid-scale for the DAC-8412 and zero scale for the DAC-8413.

The DAC-8412/DAC-8413 are available in 28-pin plastic DIP, cerdip, PLCC and LCC packages. They can be operated from a wide variety of supply and reference voltages with supplies ranging from single +5 volt to ±15 volts, and references from +2.5 to ±10 volts. Power dissipation is less than 330 mW with ±15 volt supplies and only 60 mW with a +5 volt supply.

For MIL-STD-883 applications, contact your local ADI sales office for the DAC-8412/DAC-8413/883 data sheet which specifies operation over the −55°C to +125°C temperature range. All 883 parts are also available as Standard Military Drawings 5962-91-76401MXA through -76404M3A.

NOTES

[1]All supplies can be varied ±5%, and operation is guaranteed. Device is tested with $V_{DD} = +4.75$ V.

[2]For single supply operation only ($V_{REFL} = 0.0$ V, $V_{SS} = 0.0$ V): Due to internal offset errors, INL and DNL are measured beginning at code 2 (002_H).

[3]Operation is guaranteed over this reference range, but linearity is neither tested nor guaranteed.

[4]All input control signals are specified with tr = tf = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.

Specifications subject to change without notice.

CAUTION

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected, however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper antistatic handling procedures.
3. Remove power before inserting or removing units from their sockets.
4. Analog outputs are protected from short circuit to ground or either supply.

Quad 12-Bit Serial Voltage-Output DAC

DAC8420

FEATURES
Guaranteed Monotonic Over Temperature
Excellent Matching Between DACs
Unipolar or Bipolar Operation
Buffered Voltage Outputs
High Speed Serial Digital Interface
Reset to Zero- or Center-Scale
Wide Supply Range, +5 V-Only to ±15 V
Low Power Consumption (35 mW max)
Available in 16-Pin DIP and SOL Packages

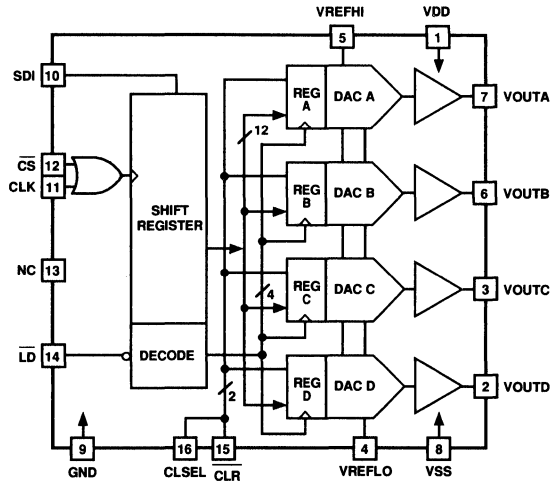
APPLICATIONS
Software Controlled Calibration
Servo Controls
Process Control and Automation
ATE

GENERAL DESCRIPTION

The DAC-8420 is a quad, 12-bit voltage-output DAC with serial digital interface, in a 16-pin package. Utilizing BiCMOS technology, this monolithic device features unusually high circuit density and low power consumption. The simple, easy-to-use serial digital input and fully buffered analog voltage outputs require no external components to achieve specified performance.

The three-wire serial digital input is easily interfaced to microprocessors running at 10 MHz rates, with minimal additional circuitry. Each DAC is addressed individually by a 16-bit serial word consisting of a 12-bit data word and an address header. The user-programmable reset control $\overline{CLR}$ forces all four DAC outputs to either zero- or midscale, asynchronously overriding the current DAC register values. The output voltage range, determined by the inputs VREFHI and VREFLO, is set by the user for positive or negative unipolar or bipolar signal swings within the supplies allowing considerable design flexibility.

FUNCTIONAL BLOCK DIAGRAM



The DAC-8420 is available in 16-pin epoxy DIP, cerdip, and wide-body SOL (small-outline surface mount) packages. Operation is specified with supplies ranging from +5 V-only to ±15 V, with references of +2.5 V to ±10 V respectively. Power dissipation when operating from ±15 V supplies is less than 255 mW (max), and only 35 mW (max) with a +5 V supply.

For applications requiring product meeting MIL-STD-883, contact your local sales office for the DAC-8420/883 data sheet, which specifies operation over the −55°C to +125°C temperature range.

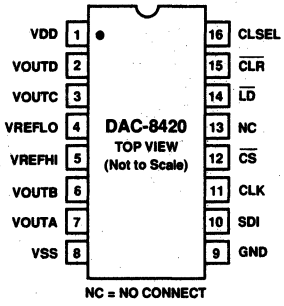
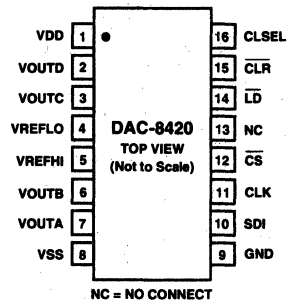
PIN CONFIGURATIONS

DIP



SOL



PIN FUNCTION DESCRIPTION

Power Supplies

VDD: Positive Supply, +5 V to +15 V.
VSS: Negative Supply, 0 V to −15 V.
GND: Digital Ground.

Clock

CLK: System Serial Data Clock Input, TTL/CMOS levels. Data presented to the input SDI is shifted into the internal serial-parallel input register on the rising edge of clock. This input is logically ORed with $\overline{CS}$.

Control Inputs

(All are CMOS/TTL compatible.)

$\overline{CLR}$: Asynchronous Clear, active low. Sets internal data registers A–D to zero or midscale, depending on current state of CLSEL. The data in the serial input shift register is unaffected by this control.

CLSEL: Determines action of $\overline{CLR}$. If HIGH, a Clear command will set the internal DAC registers A–D to midscale (800_H). If LOW, the registers are set to zero (000_H).

$\overline{CS}$: Device Chip Select, active low. This input is logically ORed with the clock and disables the serial data register input when HIGH. When LOW, data input clocking is enabled. See the Control Function Table.

$\overline{LD}$: Asynchronous DAC Register Load Control, active low. The data currently contained in the serial input shift register is shifted out to the DAC data registers on the falling edge of $\overline{LD}$, independent of $\overline{CS}$. Input data must remain stable while $\overline{LD}$ is LOW.

Data Input

(All are CMOS/TTL compatible.)

SDI: Serial Data Input. Data presented to this pin is loaded into the internal serial-parallel shift register, which shifts data in beginning with DAC address Bit A1. This input is ignored when $\overline{CS}$ is HIGH.

The format of the 16-bit serial word is:

(FIRST)															(LAST)
B0	B1	B2	B3	B4	B5	B6	B7	B8	B9	B10	B11	B12	B13	B14	B15
A1	A0	NC	NC	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
—Address Word—				(MSB)			—DAC Data Word—								(LSB)

NC = Don't Care.

Reference Inputs

VREFHI: Upper DAC ladder reference voltage input. Allowable range is (V_{DD} −2.5 V) to (V_{VREFLO} +2.5 V).

VREFLO: Lower DAC ladder reference voltage input, equal to zero scale output. Allowable range is V_{SS} to (V_{VREFHI} −2.5 V).

Analog Outputs

VOUTA through VOUTD: Four buffered DAC voltage outputs.

Table I. Control Function Logic Table

CLK[1]	$\overline{CS}$[1]	$\overline{LD}$	$\overline{CLR}$	CLSEL	Serial Input Shift Register	DAC Registers A–D
NC	H	H	L	H	No Change	Loads Midscale Value (800_H)
NC	H	H	L	L	No Change	Loads Zero-Scale Value (000_H)
NC	H	H	↑	H/L	No Change	Latches Value
↑	L	H	H	NC	Shifts Register One Bit.	No Change
L	↑	H	H	NC	Shifts Register One Bit.	No Change
H	NC (↑)	↓	H	NC	No Change	Loads the Serial Data Word[2]
H	NC	L	H	NC	No Change	Transparent[3]
NC	H	H	H	NC	No Change	No Change

NC = Don't Care.

NOTES
[1]$\overline{CS}$ and CLK are interchangeable.
[2]Returning $\overline{CS}$ HIGH while CLK is HIGH avoids an additional "false clock" of serial input data. See Note 1.
[3]Do not clock in serial data while $\overline{LD}$ is LOW.

OPERATION

Introduction

The DAC-8420 is a quad, voltage-output 12-bit DAC with serial digital input, capable of operating from a single +5 V supply. The straightforward serial interface can be connected directly to most popular microprocessors and microcontrollers, and can accept data at a 10 MHz clock rate when operating from ±15 V supplies. A unique voltage reference structure assures maximum utilization of DAC output resolution by allowing the user to set the zero- and full-scale output levels within the supply rails. The analog voltage outputs are fully buffered, and are capable of driving a 2 kΩ load. Output glitch impulse during major code transitions is a very low 64 nV-s (typ).

Digital Interface Operation

The serial input of the DAC-8420, consisting of $\overline{CS}$, SDI, and $\overline{LD}$, is easily interfaced to a wide variety of microprocessor serial ports. As shown in Table I and the Timing Diagram, while $\overline{CS}$ is LOW the data presented to the input SDI is shifted into the internal serial/parallel shift register on the rising edge of the clock, with the address MSB first, data LSB last. The data format, shown above, is two bits of DAC address and two "don't care" fill bits, followed by the 12-bit DAC data word. Once all 16 bits of the serial data word have been input, the load control $\overline{LD}$ is strobed and the word is parallel-shifted out onto the internal data bus. The two address bits are decoded and used to route the 12-bit data word to the appropriate DAC data register. See the Applications Information.

Correct Operation of $\overline{CS}$ and CLK

As mentioned in Table I, the control pins CLK and $\overline{CS}$ require some attention during a data load cycle. Since these two inputs are fed to the same logical "OR" gate, their operation is in fact identical. The user must take care to operate them accordingly in order to avoid clocking in false data bits. As shown in the Timing Diagram, CLK must be either halted HIGH, or $\overline{CS}$ brought HIGH during the last HIGH portion of the CLK following the rising edge which latched in the last data bit. Otherwise, an additional rising edge is generated by $\overline{CS}$ rising while CLK is LOW, causing $\overline{CS}$ to act as the clock and allowing a false data bit into the serial input register. The same issue must be considered in the beginning of the data load sequence also.

Using $\overline{CLR}$ and CLSEL

The CLEAR ($\overline{CLR}$) control allows the user to perform an asynchronous reset function. Asserting $\overline{CLR}$ loads all four DAC data word registers, forcing the DAC outputs to either zero-scale (000_H) or midscale (800_H), depending on the state of CLSEL as shown in the Digital Function Table. The CLEAR function is asynchronous and is totally independent of $\overline{CS}$. When $\overline{CLR}$ returns HIGH, the DAC outputs remain latched at the reset value until $\overline{LD}$ is strobed, reloading the individual DAC data word registers with either the data held in the serial input register prior to the reset, or new data loaded through the serial interface.

Table II. DAC Address Word Decode Table

A1	A0	DAC Addressed
0	0	DAC A
0	1	DAC B
1	0	DAC C
1	1	DAC D

Programming the Analog Outputs

The unique differential reference structure of the DAC-8420 allows the user to tailor the output voltage range precisely to the needs of the application. Instead of spending DAC resolution on an unused region near the positive or negative rail, the DAC-8420 allows the user to determine both the upper and lower limits of the analog output voltage range. Thus, as shown in Table III and Figure 1, the outputs of DACs A through D range between VREFHI and VREFLO, within the limits specified in the Electrical Characteristics tables. Note also that VREFHI must be greater than VREFLO.

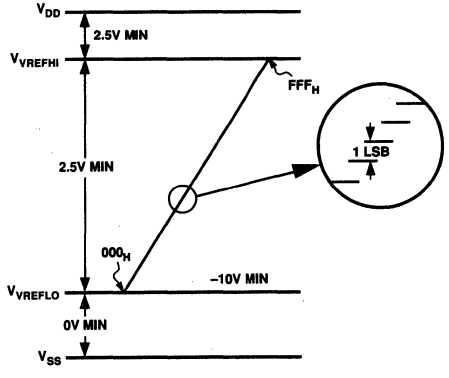


Figure 1. Output Voltage Range Programming

Table III. Analog Output Code

DAC Data Word (HEX)	V_{OUT}	Note
FFF	$VREFLO + \frac{(VREFHI-VREFLO)}{4096} \times 4095$	Full-Scale Output
801	$VREFLO + \frac{(VREFHI-VREFLO)}{4096} \times 2049$	Midscale + 1
800	$VREFLO + \frac{(VREFHI-VREFLO)}{4096} \times 2048$	Midscale
7FF	$VREFLO + \frac{(VREFHI-VREFLO)}{4096} \times 2047$	Midscale − 1
000	$VREFLO + \frac{(VREFHI-VREFLO)}{4096} \times 0$	Zero-Scale

VREFHI Input Requirements

The DAC-8420 utilizes a unique, patented DAC switch driver circuit which compensates for different supply, reference voltage, and digital code inputs. This ensures that all DAC ladder switches are always biased equally, ensuring excellent linearity under all conditions. Thus, as indicated in the specifications, the VREFHI input of the DAC-8420 will require both sourcing and sinking current capability from the reference voltage source. Many positive voltage references are intended as current sources only, and offer little sinking capability. The user should consider references such as the AD584, AD586, AD587, AD588, AD780, and REF-43 in this application.

APPLICATIONS

Power Supply Bypassing and Grounding

In any circuit where accuracy is important, careful consideration of the power supply and ground return layout helps to ensure the rated performance. The DAC-8420 has a single ground pin that is internally connected to the digital section as the logic reference level. The first thought may be to connect this pin to the digital ground; however, in large systems the digital ground is often noisy because of the switching currents of other digital circuitry. Any noise that is introduced at the ground pin could couple into the analog output. Thus, to avoid error causing digital noise in the sensitive analog circuitry, the ground pin should be connected to the system analog ground. The ground path (circuit board trace) should be as wide as possible to reduce any effects of parasitic inductance and ohmic drops. A ground plane is recommended if possible. The noise immunity of the on-board digital circuitry, typically in the hundreds of millivolts, is well able to reject the common-mode noise typically seen between system analog and digital grounds. Finally, the analog and digital ground should be connected together at a single point in the system to provide a common reference. This is preferably done at the power supply.

Good grounding practice is essential to maintaining analog performance in the surrounding analog support circuitry as well. With two reference inputs, and four analog outputs capable of moderate bandwidth and output current, there is a significant potential for ground loops. Again, a ground plane is recommended as the most effective solution to minimizing errors due to noise and ground offsets.

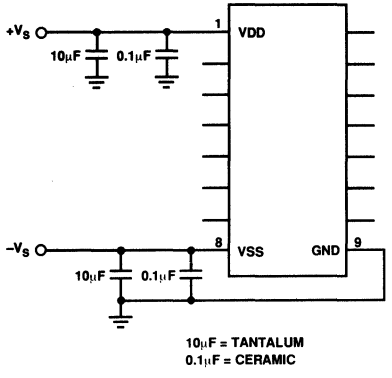

Figure 26. Recommended Supply Bypassing Scheme

The DAC-8420 should have ample supply bypassing, located as close to the package as possible. Figure 26 shows the recommended capacitor values of 10 μF in parallel with 0.1 μF. The 0.1 μF cap should have low "Effective Series Resistance" (ESR) and "Effective Series Inductance" (ESI), such as the common ceramic types, which provide a low impedance path to ground at high frequencies to handle transient currents due to internal logic switching. In order to preserve the specified analog performance of the device, the supply should be as noise free as possible. In the case of 5 V only systems it is desirable to use the same 5 V supply for both the analog circuitry and the digital portion of the circuit. Unfortunately, the typical 5 V supply is extremely noisy due to the fast edge rates of the popular CMOS logic families which induce large inductive voltage spikes, and busy microcontroller or microprocessor busses which commonly have large current spikes during bus activity. However, by properly filtering the supply as shown in Figure 27, the digital 5 V supply can be used. The inductors and capacitors generate a filter that not only rejects noise due to the digital circuitry, but also filters out the lower frequency noise of switch mode power supplies. The analog supply should be connected as close as possible to the origin of the digital supply to minimize noise pick-up from the digital section.

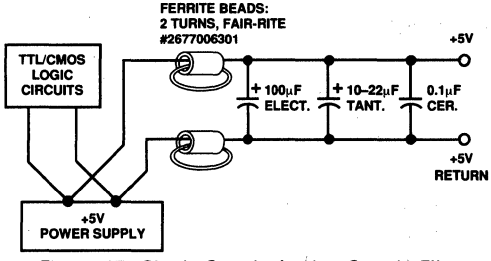

Figure 27. Single-Supply Analog Supply Filter

Analog Outputs

The DAC-8420 features buffered analog voltage outputs capable of sourcing and sinking up to 5 mA when operating from ±15 V supplies, eliminating the need for external buffer amplifiers in most applications while maintaining specified accuracy over the rated operating conditions. The buffered outputs are simply an op amp connected as a voltage follower, and thus have output characteristics very similar to the typical operational amplifier. These amplifiers are short-circuit protected. The designer should verify that the output load meets the capabilities of the device, in terms of both output current and load capacitance. The DAC-8420 is stable with capacitive loads up to 2 nF typical. However, any capacitive load will increase the settling time, and should be minimized if speed is a concern.

The output stage includes a p-channel MOSFET to pull the output voltage down to the negative supply. This is very important in single supply systems, where VREFLO usually has the same potential as the negative supply. With no load, the zero-scale output voltage in these applications will be less than 500 μV typically, or less than 1 LSB when V_{VREFHI} = 2.5 V. However, when sinking current this voltage does increase because of the finite impedance of the output stage. The effective value of the pull-down resistor in the output stage is typically 320 Ω. With a 100 kΩ resistor connected to +5 V, the resulting zero-scale output voltage is 16 mV. Thus, the best single supply operation is obtained with the output load connected to ground, so the output stage does not have to sink current.

Like all amplifiers, the DAC-8420 output buffers do generate voltage noise, 52 nV/$\sqrt{Hz}$ typically. This is easily reduced by adding a simple RC low-pass filter on each output.

Reference Configuration

The two reference inputs of the DAC-8420 allow a great deal of flexibility in circuit design. The user must take care, however, to observe the minimum voltage input levels on VREFHI and VREFLO to maintain the accuracy shown in the data sheet. These input voltages can be set anywhere across a wide range within the supplies, but must be a minimum of 2.5 V apart in any case. See Figure 1. A wide output voltage range can be obtained with ±5 V references, which can be provided by the AD588 as shown in Figure 28. Many applications utilize the DACs to synthesize symmetric bipolar wave forms, which requires an accurate, low drift bipolar reference. The AD588 provides both voltages and needs no external components. Additionally, the part is trimmed in production for 12-bit accuracy over the full temperature range without user calibration. Performing a Clear with the reset select CLSEL HIGH allows the user to easily reset the DAC outputs to midscale, or zero volts in these applications.

When driving the reference inputs VREFHI and VREFLO, it is important to note that VREFHI both sinks and sources current, and that the input currents of both are code dependent. Many voltage reference products have limited current sinking capability and must be buffered with an amplifier to drive VREFHI, in order to maintain overall system accuracy. The input VREFLO, however, has no such requirement.

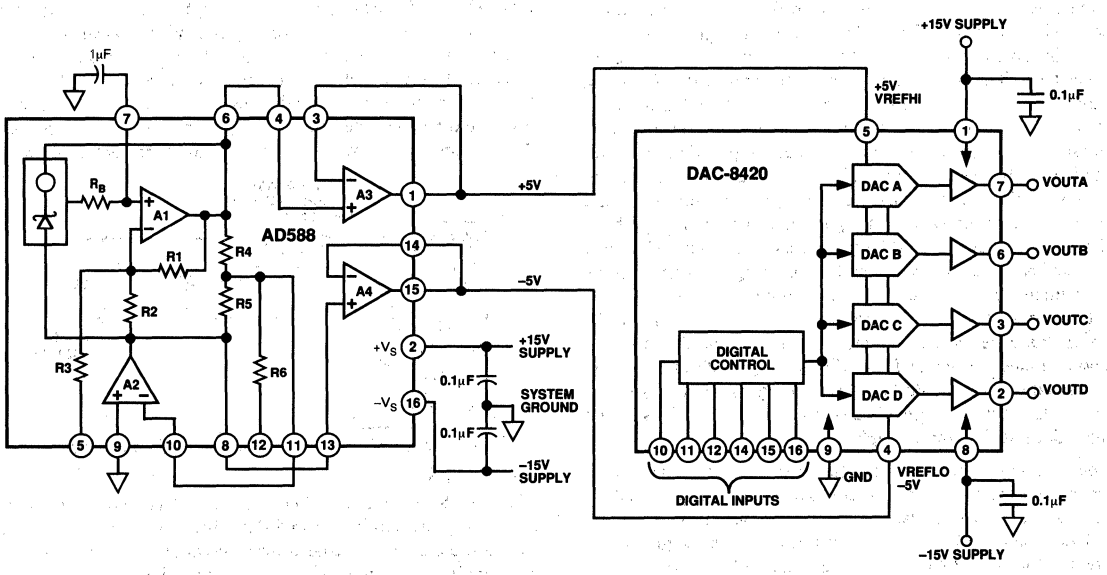

Figure 28. ±10 V Bipolar Reference Configuration Using the AD588

For a single 5 V supply, V_{VREFHI} is limited to at most 2.5 V, and must always be at least 2.5 V less than the positive supply to ensure linearity of the device. For these applications, the REF-43 is an excellent low drift 2.5 V reference that consumes only 450 μA (max). It works well with the DAC-8420 in a single 5 V system as shown in Figure 29.

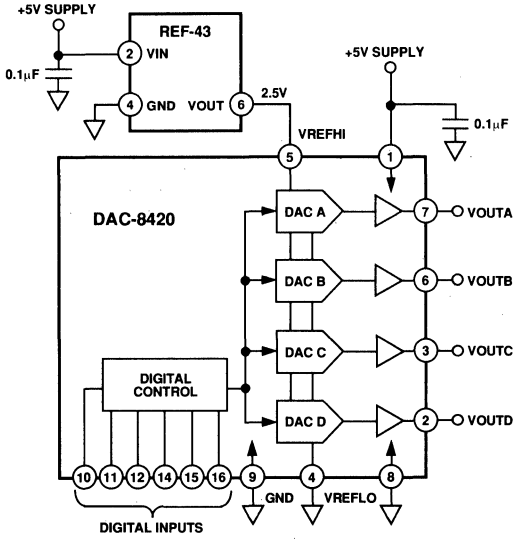

Figure 29. +5 V Single Supply Operation Using REF-43

Isolated Digital Interface

Because the DAC-8420 is ideal for generating accurate voltages in process control and industrial applications, due to noise, safety requirements, or distance, it may be necessary to isolate it from the central controller. This can be easily achieved by using opto-isolators, which are commonly used to provide electrical isolation in excess of 3 kV. Figure 30 shows a simple 3-wire interface scheme to control the clock, data, and load pulse. For normal operation, $\overline{CS}$ is tied permanently LOW so that the DAC-8420 is always selected. The resistor and capacitor on the $\overline{CLR}$ pin provide a power-on reset with 10 ms time constant. The three opto-isolators are used for the SDI, CLK, and $\overline{LD}$ lines.

One opto-isolated line ($\overline{LD}$) can be eliminated from this circuit by adding an inexpensive 4-bit TTL Counter to generate the Load pulse for the DAC-8420 after 16 clock cycles. The counter is used to count of the number of clock cycles loading serial data to the DAC-8420. After all 16 bits have been clocked into the converter, the counter resets, and a load pulse is generated on clock 17. In either circuit, the DAC-8420's serial interface provides a simple, low cost method of isolating the digital control.

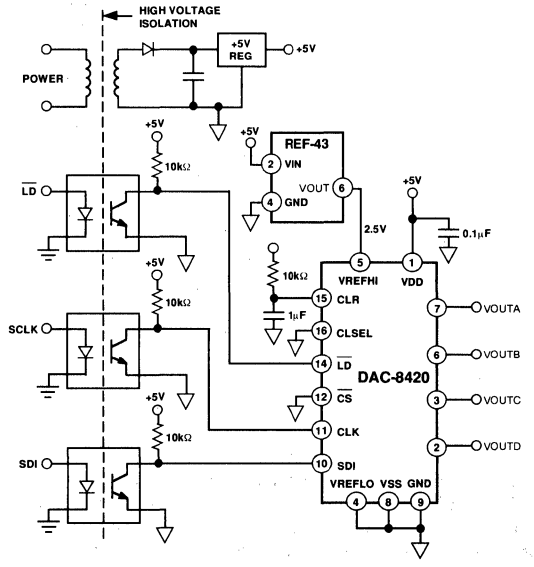

Figure 30. Opto-Isolated 3-Wire Interface

Dual Window Comparator

Often a comparator is needed to signal an out-of-range warning. Combining the DAC-8420 with a quad comparator such as the CMP-04 provides a simple dual window comparator with adjustable trip points as shown in Figure 31. This circuit can be operated with either a dual or a single supply. For the A input channel, DAC B sets the low trip point and DAC A sets the upper trip point. The CMP-04 has open-collector outputs that are connected together in "Wired-OR" configuration to generate an out-of-range signal. For example, when VINA goes below the trip point set by DAC B, comparator C2 pulls the output down, turning the red LED on. The output can also be used as a logic signal for further processing.

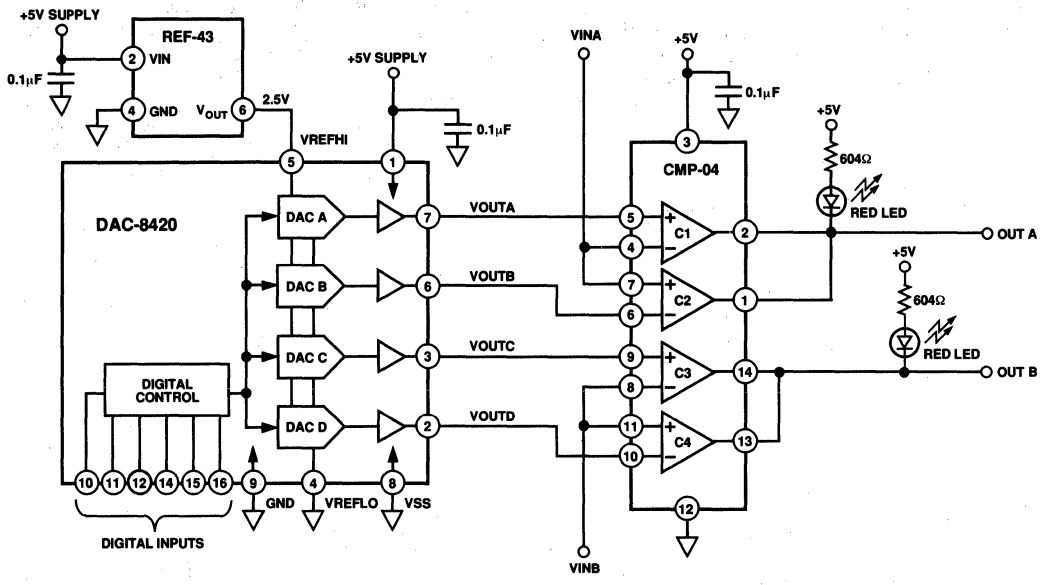

Figure 31. Dual Programmable Window Comparator

MC68HC11 Microcontroller Interfacing

Figure 32 shows a serial interface between the DAC-8420 and the MC68HC11 8-bit microcontroller. The SCK output of the 68HC11 drives the CLK input of the DAC, and the MOSI port outputs the serial data to load into the SDI input of the DAC. The port lines PD5, PC0, PC1, and PC2 provide the controls to the DAC as shown.

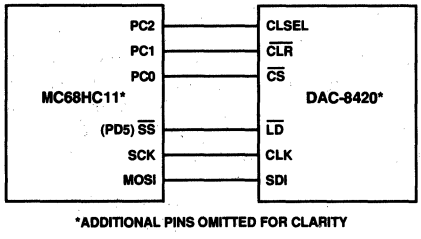

Figure 32. MC68HC11 Microcontroller Interface

For correct operation, the 68HC11 should be configured such that its CPOL bit and CPHA bit are both set to 1. In this configuration, serial data on MOSI of the 68HC11 is valid on the rising edge of the clock, which is the required timing for the DAC-8420. Data is transmitted in 8-bit bytes (MSB first), with only eight rising clock edges occurring in the transmit cycle. To load data to the DAC-8420's input register, PC0 is taken low and held low during the entire loading cycle. The first 8 bits are shifted in address first, immediately followed by another 8 bits in the second least-significant byte to load the complete 16-bit word. At the end of the second byte load, PC0 is then taken high. To prevent an additional advancing of the internal shift register, SCK must already be asserted before PC0 is taken high. To transfer the contents of the input shift register to the DAC register, PD5 is then taken low, asserting the $\overline{LD}$ input of the DAC and completing the loading process. PD5 should return high before the next load cycle begins. The DAC-8420's $\overline{CLR}$ input, controlled by the output PC1, provides an asynchronous clear function.

Quad 8-Bit Voltage Out CMOS DAC Complete with Internal 10V Reference

DAC8426

FEATURES

- **No Adjustments Required, Total Error ± 1LSB Max Over Temperature**
- **Four Voltage-Output DACs on a Single Chip**
- **Internal 10V bandgap Reference**
- **Operates from Single +15V Supply**
- **Fast 50ns Data Load Time, All Temperatures**
- **Pin-for-Pin Replacement for PM-7226 and AD7226, Eliminates External Reference**

APPLICATIONS

- **Process Controls**
- **Multi-Channel Microprocessor Controlled:**
  - **System Calibration**
  - **Op Amp Offset and Gain Adjust**
  - **Level and Threshold Setting**

GENERAL DESCRIPTION

The DAC-8426 is a complete quad voltage output D/A converter with internal reference. This product fits directly into any existing 7226 socket where the user currently has a 10V external reference. The external reference is no longer necessary. The internal reference of the DAC-8426 is laser-trimmed to ±0.4% offering a 25ppm/°C temperature coefficient and 5mA of external load driving capability.

The DAC-8426 contains four 8-bit voltage-output CMOS D/A converters on a single chip. A 10V output bandgap reference sets the output full-scale voltage. The circuit also includes four input latches and interface control logic.

One of the four latches, selected by the address inputs, is loaded from the 8-bit data bus input when the write strobe is active low. All digital inputs are TTL/CMOS (5V) compatible. The on-board amplifiers can drive up to 10mA from either a single or dual supply. The on-board reference that is always connected to the internal DACs has 5mA available to drive external devices.

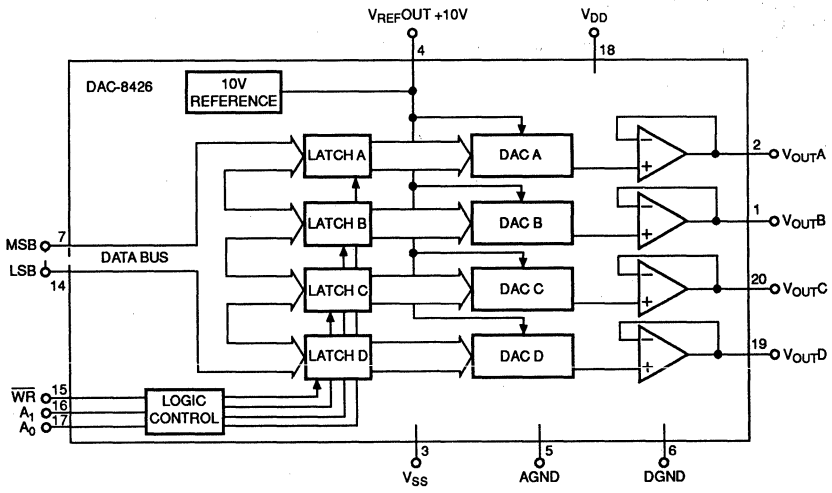
* For devices processed in total compliance to MIL-STD-883, add /883 after part number. Consult factory for 883 data sheet.

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

†† For availability and burn-in information on SO and PLCC packages, contact your local sales office.

SIMPLIFIED SCHEMATIC



This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

GENERAL DESCRIPTION *Continued*

Its compact size, low power, and economical cost-per-channel, make the DAC-8426 attractive for applications requiring multiple D/A converters without sacrificing circuit-board space. System reliability is also increased due to reduced parts count.

PMI's advanced oxide-based, silicon-gate, CMOS process allows the DAC-8426's analog and digital circuitry to be manufactured on the same chip. This, coupled with PMI's highly stable thin-film R-2R resistor ladder, aids in matching and temperature tracking between DACs.

PIN CONNECTIONS

THERMAL RESISTANCE

PACKAGE TYPE	Θ_{JA} (Note 2)	Θ_{JC}	UNITS
20-Pin CerDIP (R)	70	7	°C/W
20-Pin Plastic DIP (P)	61	24	°C/W
20-Pin SOL (S)	80	22	°C/W

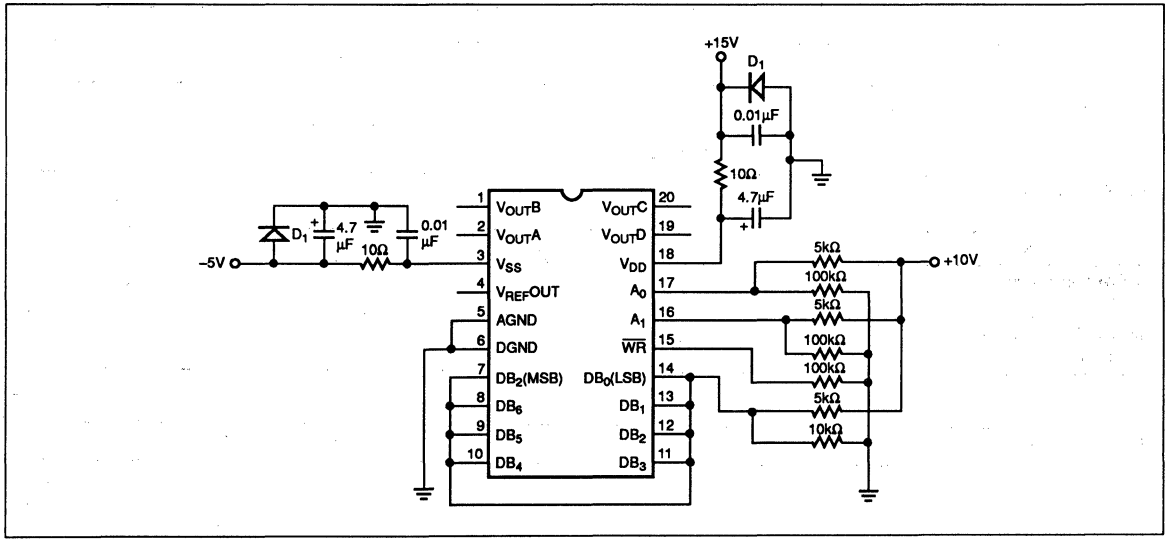
NOTES:

1. Outputs may be shorted to any terminal provided the package power dissipation is not exceeded. Typical output short-circuit current to AGND is 50mA.
2. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP and P-DIP packages; Θ_{JA} is specified for device soldered to printed circuit board for SOL package.

CAUTION:

1. Do not apply voltages higher than V_{DD} or less than V_{SS} potential on any terminal.
2. The digital control inputs are zener-protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam at all times until ready to use.
3. Do not insert this device into powered sockets. Remove power before insertion or removal.
4. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to device.

BURN-IN CIRCUIT



ELECTRICAL CHARACTERISTICS: V_{DD} = +15V ±10%, AGND = DGND = 0V, V_{SS} = 0V, T_A = –55°C to +125°C applies for DAC-8426AR/BR, T_A = –40°C to +85°C applies for DAC-8426ER/EP/FR/FP/FS, unless otherwise noted.

+5 V, Serial Input Complete 12-Bit DAC

DAC8512

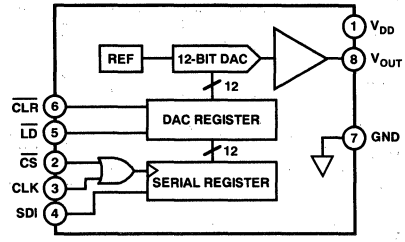
FEATURES

Space Saving SO-8 or Mini-DIP Packages
Complete, Voltage Output with Internal Reference
1 mV/Bit with 4.095 V Full Scale
Single +5 Volt Operation
No External Components
3-Wire Serial Data Interface, 20 MHz Data Loading Rate
Low Power: 2.5 mW

APPLICATIONS

Portable Instrumentation
Digitally Controlled Calibration
Servo Controls
Process Control Equipment
PC Peripherals

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The DAC-8512 is a complete serial input, 12-bit, voltage output digital-to-analog converter designed to operate from a single +5 V supply. It contains the DAC, input shift register and latches, reference and a rail-to-rail output amplifier. Built using a CBCMOS process, these monolithic DACs offer the user low cost, and ease of use in +5 V only systems.

Coding for the DAC-8512 is natural binary with the MSB loaded first. The output op amp can swing to either rail and is set to a range of 0 V to +4.095 V—for a one-millivolt-per-bit resolution. It is capable of sinking and sourcing 5 mA. An on-chip reference is laser trimmed to provide an accurate full-scale output voltage of 4.095 V.

Serial interface is high speed, three-wire, DSP compatible with data in (SDI), clock (CLK) and load strobe (LD). There is also a chip-select pin for connecting multiple DACs.

A CLR input sets the output to zero scale at power on or upon user demand.

The DAC-8512 is specified over the extended industrial (−40°C to +85°C) temperature range. DAC-8512s are available in plastic DIPs and SO-8 surface mount packages.

NOTES
[1]All input control signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.
[2]1 LSB = 1 mV for 0 V to +4.095 V output range.
[3]Includes internal voltage reference error.
[4]These parameters are guaranteed by design and not subject to production testing.
[5]The settling time specification does not apply for negative going transitions within the last 6 LSBs of ground. Some devices exhibit double the typical settling time in this 6 LSB region.

Specifications subject to change without notice.

WAFER TEST LIMITS (@ V_{DD} = +5.0 V ± 5%, T_A = +25°C, applies to part number DAC8512GBC only, unless otherwise noted)

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model	INL (LSB)	Temperature Range	Package Description	Package Option*
DAC8512EP	±1	−40°C to +85°C	8-Pin P-DIP	N-8

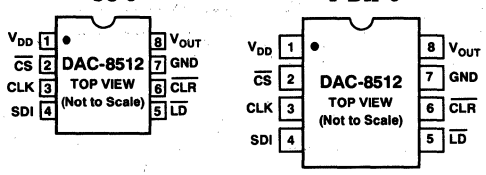
NOTES
[1] ↑+ positive logic transition; ↓− negative logic transition; X = Don't Care.
[2] $\overline{CS}$ and CLK are interchangeable.
[3] Returning $\overline{CS}$ HIGH avoids an additional "false clock" of serial data input.
[4] Do not clock in serial data while $\overline{LD}$ is LOW.

PIN CONFIGURATION

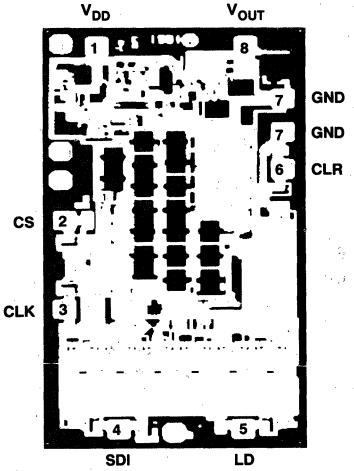
SO-8 / P-DIP-8



PIN DESCRIPTIONS

Pin	Name	Description
1	V_{DD}	Positive Supply. Nominal value +5 V, ± 5%.
2	$\overline{CS}$	Chip Select. Active low input.
3	CLK	Clock input for the internal serial input shift register.
4	SDI	Serial Data Input. Data on this pin is clocked into the internal serial register on positive clock edges of the CLK pin. The Most Significant Bit (MSB) is loaded first.
5	$\overline{LD}$	Active low input which writes the serial register data into the DAC register. Asynchronous input.
6	$\overline{CLR}$	Active low digital input that clears the DAC register to zero, setting the DAC to minimum scale. Asynchronous input.
7	GND	Analog ground for the DAC. This also serves as the digital logic ground reference voltage.
8	V_{OUT}	Voltage output from the DAC. Fixed output voltage range of 0 V to 4.095 V with 1 mV/LSB. An internal temperature stabilized reference maintains a fixed full-scale voltage independent of time, temperature and power supply variations.

DICE CHARACTERISTICS



SUBSTRATE IS COMMON WITH V_{DD}.

NUMBER OF TRANSISTORS: 642
DIE SIZE: 0.055 inch × 0.106 inch; 5830 sq mils

OPERATION

The DAC-8512 is a complete ready to use 12-bit digital-to-analog converter. It contains a voltage-switched, 12-bit, laser-trimmed DAC, a curvature-corrected bandgap reference, a rail-to-rail output op amp, a DAC register, and a serial data input register. The serial data interface consists of a CLK, serial data in (SDI), and a load strobe ($\overline{LD}$). This basic 3-wire interface offers maximum flexibility for interface to the widest variety of serial data input loading requirements. In addition a $\overline{CS}$ select is provided for multiple packaging loading and a power on reset $\overline{CLR}$ pin to simplify start or periodic resets.

D/A CONVERTER SECTION

The DAC is a 12-bit voltage mode device with an output that swings from GND potential to the 2.5 volt internal bandgap voltage. It uses a laser trimmed R-2R ladder which is switched by N channel MOSFETs. The output voltage of the DAC has a constant resistance independent of digital input code. The DAC output is internally connected to the rail-to-rail output op amp.

AMPLIFIER SECTION

The DAC's output is buffered by a low power consumption precision amplifier. This amplifier contains a differential PNP pair input stage which provides low offset voltage and low noise, as well as the ability to amplify the zero-scale DAC output voltages. The rail-to-rail amplifier is configured in a gain of 1.6384 (= 4.095 V/2.5 V) in order to set the 4.095 volt full-scale output (1 mV/LSB). See Figure 3 for an equivalent circuit schematic of the analog section.

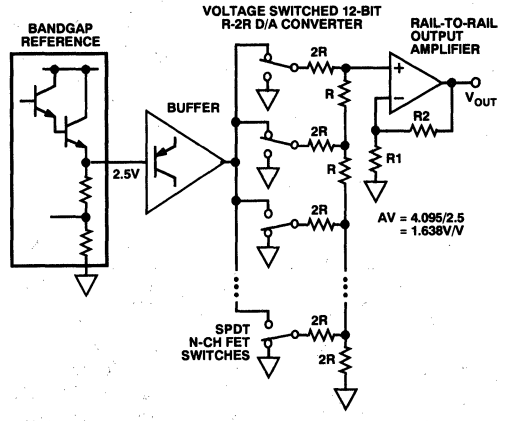


Figure 3. Equivalent DAC-8512 Schematic of Analog Portion

The op amp has a 16 µs typical settling time to 0.01%. There are slight differences in settling time for negative slewing signals vs. positive. See the oscilloscope photos in the typical performances section of this data sheet.

OUTPUT SECTION

The rail-to-rail output stage of this amplifier has been designed to provide precision performance while operating near either power supply.

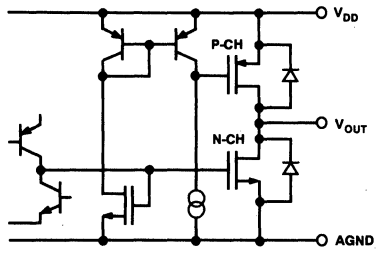

Figure 4. Equivalent Analog Output Circuit

Figure 4 shows an equivalent output schematic of the rail-to-rail amplifier with its N channel pull down FETs that will pull an output load directly to GND. The output sourcing current is provided by a P channel pull up device that can supply GND terminated loads, especially at the low supply tolerance values of 4.75 volts. Figures 5 and 6 provide information on output swing performance near ground and full-scale as a function of load. In addition to resistive load driving capability the amplifier has also been carefully designed and characterized for up to 500 pF capacitive load driving capability.

POWER SUPPLY

The very low power consumption of the DAC-8512 is a direct result of a circuit design optimizing use of the CBCMOS process. By using the low power characteristics of the CMOS for the logic, and the low noise, tight matching of the complementary bipolar transistors good analog accuracy is achieved.

For power consumption sensitive applications it is important to note that the internal power consumption of the DAC-8512 is strongly dependent on the actual logic input voltage levels present on the SDI, $\overline{CS}$, $\overline{LD}$, and $\overline{CLR}$ pins. Since these inputs are standard CMOS logic structures they contribute static power dissipation dependent on the actual driving logic V_{OH} and V_{OL} voltage levels. The graph in Figure 9 shows the effect on total DAC-8512 supply current as a function of the actual value of input logic voltage. Consequently use of CMOS logic vs. TTL minimizes power dissipation in the static state. A V_{IL} = 0 V on the SDI, $\overline{CS}$ and CLR pins provides the lowest standby power dissipation of 2.5 mW (500 μA × 5 V).

As with any analog system, it is recommended that the DAC-8512 power supply be bypassed on the same PC card that contains the chip. Figure 10 shows the power supply rejection versus frequency performance. This should be taken into account when using higher frequency switched mode power supplies with ripple frequencies of 100 kHz and higher.

One advantage of the rail-to-rail output amplifier used in the DAC-8512 is the wide range of usable supply voltage. The part is fully specified and tested over temperature for operation from +4.75 V to +5.25 V. If reduced linearity and source current capability near full scale can be tolerated, operation of the DAC-8512 is possible down to +4.3 volts. The minimum operating supply voltage versus load current plot, in Figure 11, provides information for operation below V_{DD} = +4.75 V.

TIMING AND CONTROL

The DAC-8512 has a separate serial input register from the 12-bit DAC register that allows preloading of a new data value into the serial register without disturbing the present DAC output voltage. After the new value is fully loaded in the serial input register it can be asynchronously transferred to the DAC register by strobing the $\overline{LD}$ pin. The DAC register uses a level sensitive $\overline{LD}$ strobe that should be returned high before any new data is loaded into the serial input register. At any time the contents of the DAC register can be reset to zero by strobing the $\overline{CLR}$ pin which causes the DAC output voltage to go to zero volts. All of the timing requirements are detailed in Figure 1 along with the Table I Control-Logic Truth Table.

APPLICATIONS SECTION

Power Supplies, Bypassing, and Grounding

All precision converter products require careful application of good grounding practices to maintain full rated performance. Because the DAC-8512 has been designed for +5 V applications, it is ideal for those applications under microprocessor or microcomputer control. In these applications, digital noise is prevalent; therefore, special care must be taken to assure that its inherent precision is maintained. This means that particularly good engineering judgment should be exercised when addressing the power supply, grounding, and bypassing issues using the DAC-8512.

The power supply used for the DAC-8512 should be well filtered and regulated. The device has been completely characterized for a +5 V supply with a tolerance of ±5%. Since a +5 V logic supply is almost universally available, it is not recommended to connect the DAC directly to an unfiltered logic supply without careful filtering. Because it is convenient, a designer might be inclined to tap a logic circuit's supply for the DAC's supply. Unfortunately, this is not wise because fast logic with nanosecond transition edges induce high current pulses. The high transient current pulses can generate glitches hundreds of millivolts in amplitude due to wiring resistances and inductances. This high frequency noise will corrupt the analog circuits internal to the DAC and cause errors. Even though their spike noise is lower in amplitude, directly tapping the output of a +5 V system supply can cause errors because these supplies are of the switching regulator type that can and do generate a great deal of high frequency noise. Therefore, the DAC and any associated analog circuitry should be powered directly from the system power supply outputs using appropriate filtering. Figure 23 illustrates how a clean, analog-grade supply can be generated from a +5 V logic supply using a differential LC filter with separate power supply and return lines. With the values shown, this filter can easily handle 100 mA of load current without saturating the ferrite cores. Higher current capacity can be achieved with larger ferrite cores. For lowest noise, all electrolytic capacitors should be low ESR (Equivalent Series Resistance) type.

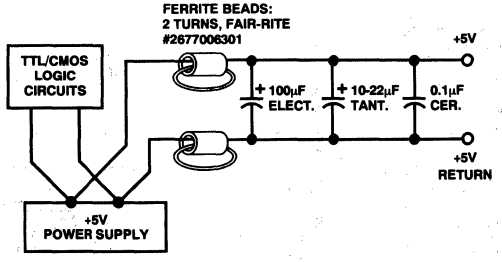

Figure 23. Properly Filtering a +5 V Logic Supply Can Yield A High Quality Analog Supply

In order to fit the DAC-8512 in an 8-pin package, it was necessary to use only one ground connection to the device. The ground connection of the DAC serves as the return path for supply currents as well as the reference point for the digital input thresholds. The ground connection also serves as the supply rail for the internal voltage reference and the output amplifier. Therefore, to minimize any errors, it is recommended that the ground connection of the DAC-8512 be connected to a high quality analog ground, such as the one described above. Generous bypassing of the DAC's supply goes a long way in reducing supply line-induced errors. Local supply bypassing consisting of a 10 µF tantalum electrolytic in parallel with a 0.1 µF ceramic is recommended. The decoupling capacitors should be connected between the DAC's supply pin (Pin 1) and the analog ground (Pin 7). Figure 24 shows how the ground and bypass connections should be made to the DAC-8512.

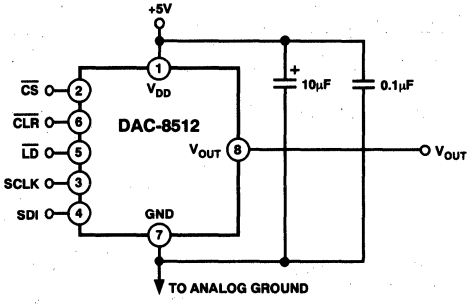

Figure 24. Recommended Grounding and Bypassing Scheme for the DAC-8512

Unipolar Output Operation

This is the basic mode of operation for the DAC-8512. As shown in Figure 24, the DAC-8512 has been designed to drive loads as low as 2 kΩ in parallel with 500 pF. The code table for this operation is shown in Table II.

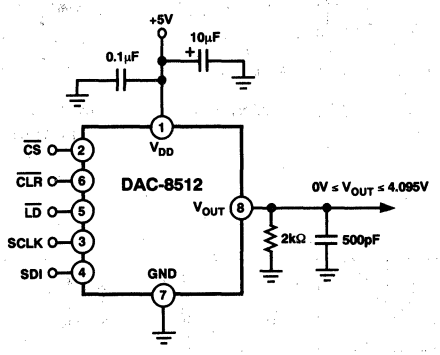

Figure 25. Unipolar Output Operation

Table II. Unipolar Code Table

Hexadecimal Number in DAC Register	Decimal Number in DAC Register	Analog Output Voltage (V)
FFF	4095	+4.095
801	2049	+2.049
800	2048	+2.048
7FF	2047	+2.047
000	0	0

Operating the DAC-8512 on +12 V or +15 V Supplies Only
Although the DAC-8512 has been specified to operate on a single, +5 V supply, a single +5 V supply may not be available in many applications. Since the DAC-8512 consumes no more than 2.5 mA, maximum, then an integrated voltage reference, such as the REF-02, can be used as the DAC-8512 +5 V supply. The configuration of the circuit is shown in Figure 26. Notice that the reference's output voltage requires no trimming because of the REF-02's excellent load regulation and tight initial output voltage tolerance. Although the maximum supply current of the DAC-8512 is 2.5 mA, local bypassing of the REF-02's output with at least 0.1 μF at the DAC's voltage supply pin is recommended to prevent the DAC's internal digital circuits from affecting the DAC's internal voltage reference.

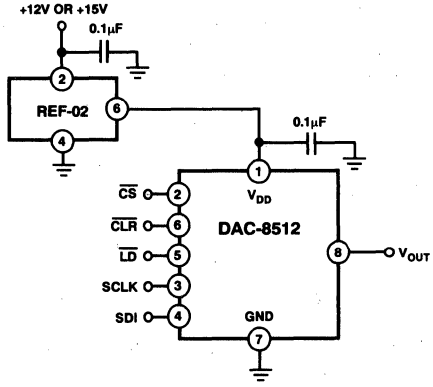

Figure 26. Operating the DAC-8512 on +12 V or +15 V Supplies Using a REF-02 Voltage Reference

Measuring Offset Error
One of the most commonly specified end-point errors associated with real world nonideal DACs is offset error.

In most DAC testing, the offset error is measured by applying the zero-scale code and measuring the output deviation from 0 volt. There are some DACs where offset errors may be present but not observable at the zero scale because of other circuit limitations (for example, zero coinciding with single-supply ground). In these DACs, nonzero output at zero code cannot be read as the offset error. In the DAC-8512, for example, the zero-scale error is specified to be ±3 LSBs. Since zero scale coincides with zero volt, it is not possible to measure negative offset error.

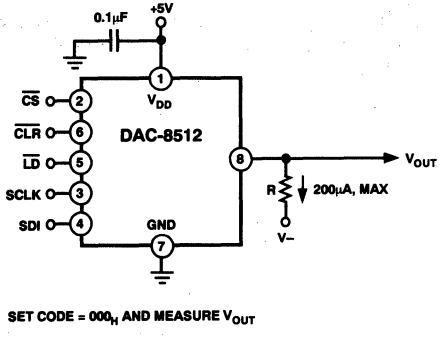

Figure 27. Measuring Zero-Scale or Offset Error

By adding a pull-down resistor from the output of the DAC-8512 to a negative supply as shown in Figure 27, offset errors can now be read at zero code. This configuration forces the output p-channel MOSFET to source current to the negative supply thereby allowing the designer to determine in which direction the offset error appears. The value of the resistor should be such that, at zero code, current through the resistor is 200 μA, maximum.

Bipolar Output Operation
Although the DAC-8512 has been designed for single-supply operation, bipolar operation is achievable using the circuit illustrated in Figure 28. The circuit uses a single-supply, rail-to-rail OP-295 op amp and the REF-03 to generate the −2.5 V reference required to level-shift the DAC output voltage. Note that the −2.5 V reference was generated without the use of precision resistors. The circuit has been configured to provide an output voltage in the range $-5\ V \le V_{OUT} \le +5\ V$ and is coded in complementary offset binary. Although each DAC LSB corresponds to 1 mV, each output LSB has been scaled to 2.44 mV. Table III provides the relationship between the digital codes and output voltage.

The transfer function of the circuit is given by:

$$V_O = -1\ mV \times Digital\ Code \times \frac{R4}{R1} + 2.5 \times \frac{R4}{R2}$$

and, for the circuit values shown, becomes:

$$V_O = -2.44\ mV \times Digital\ Code + 5\ V$$

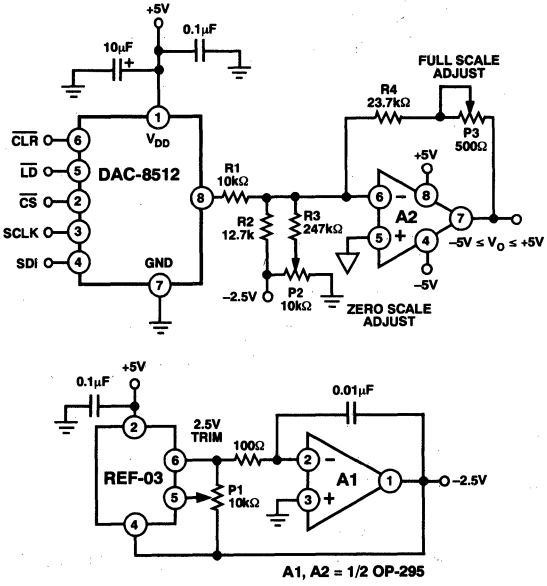

Figure 28. Bipolar Output Operation

Table III. Bipolar Code Table

Hexadecimal Number in DAC Register	Decimal Number in DAC Register	Analog Output Voltage (V)
FFF	4095	−4.9976
801	2049	−2.44E−3
800	2048	0
7FF	2047	+2.44E−3
000	0	+5

To maintain monotonicity and accuracy, R1, R2, and R4 should be selected to match within 0.01% and must all be of the same (preferably metal foil) type to assure temperature coefficient matching. Mismatching between R1 and R2 causes offset and gain errors while an R4 to R1 and R2 mismatch yields gain errors.

For applications that do not require high accuracy, the circuit illustrated in Figure 29 can also be used to generate a bipolar output voltage. In this circuit, only one op amp is used and no potentiometers are used for offset and gain trim. The output voltage is coded in offset binary and is given by:

$$V_O = 1\,mV \times Digital\ Code \times \left(\frac{R4}{R3 + R4}\right) \times \left(1 + \frac{R2}{R1}\right) - 2.5 \times \frac{R2}{R1}$$

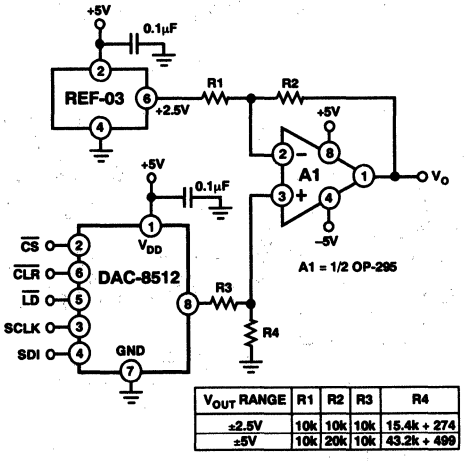

Figure 29. Bipolar Output Operation without Trim

For the ±2.5 V output range and the circuit values shown in the table, the transfer equation becomes:

$$V_O = 1.22\,mV \times Digital\ Code - 2.5\,V$$

Similarly, for the ±5 V output range, the transfer equation becomes:

$$V_o = 2.44\,mV \times Digital\ Code - 5\,V$$

Generating a Negative Supply Voltage

Some applications may require bipolar output configuration but only have a single power supply rail available. This is very common in data acquisition systems using microprocessor-based systems. In these systems, +12 V, +15 V, and/or +5 V are only available. Shown in Figure 30 is a method of generating a negative supply voltage using one CD4049, a CMOS hex inverter, operating on +12 V or +15 V. The circuit is essentially a charge pump where two of the six are used as an oscillator. For the values shown, the frequency of oscillation is approximately 3.5 kHz and is fairly insensitive to supply voltage because R1 > 2 × R2. The remaining four inverters are wired in parallel for higher output current. The square wave output is level translated by C2 to a negative-going signal, rectified using a pair of 1N4001s, and then filtered by C3. With the values shown, the charge pump will provide an output voltage of −5 V for current loadings in the range 0.5 mA ≤ I_{OUT} ≤ 10 mA with a +15 V supply and 0.5 mA ≤ I_{OUT} ≤ 7 mA with a +12 V supply.

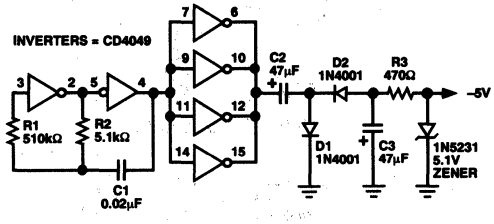

Figure 30. Generating a −5 V Supply When Only +12 V or +15 V Is Available

A High-Compliance, Digitally Controlled Precision Current Source

The circuit in Figure 31 shows the DAC-8512 controlling a high-compliance precision current source using an AMP-05 instrumentation amplifier. The AMP-05's reference pin becomes the input, and the "old" inputs now monitor the voltage across a precision current sense resistor, R_{CS}. Voltage gain is set to unity, so the transfer function is given by the following equation:

$$I_{OUT} = \frac{V_{IN}}{R_{CS}}$$

If R_{CS} equals 100 Ω, the output current is limited to +10 mA with a 1 V input. Therefore, each DAC LSB corresponds to 2.4 μA. If a bipolar output current is required, then the circuit in Figure 28 can be modified to drive the AMP-05's reference pin with a ±1 V input signal.

Potentiometer P1 trims the output current to zero with the input at 0 V. Fine gain adjustment can be accomplished by adjusting R1 or R2.

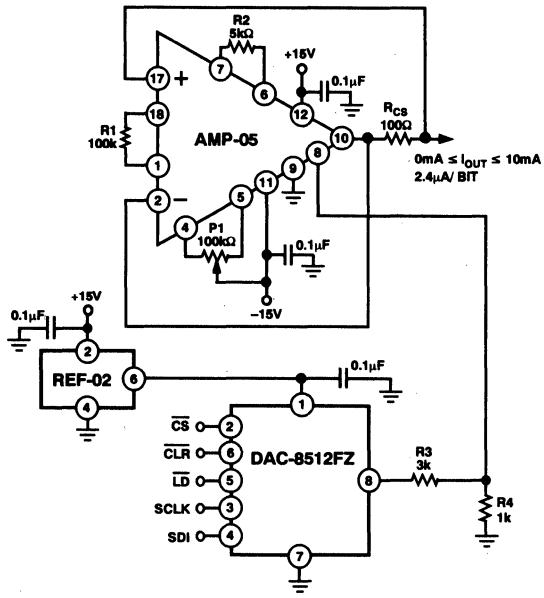

Figure 31. A High-Compliance, Digitally Controlled Precision Current Source

A Single-Supply, Programmable Current Source

The circuit in Figure 32 shows how the DAC-8512 can be used with an OP-295 single-supply, rail-to-rail output op amp to provide a digitally programmable current sink from V_{SOURCE} that consumes less than 3.8 mA, maximum. The DAC's output voltage is applied across R1 by placing the 2N2222 transistor in the OP-295's feedback loop. For the circuit values shown, the full-scale output current is 1 mA which is given by the following equation:

$$I_{OUT} = \frac{DW \times 4.095\ V}{R1}$$

where DW = DAC-8512's binary digital input code.

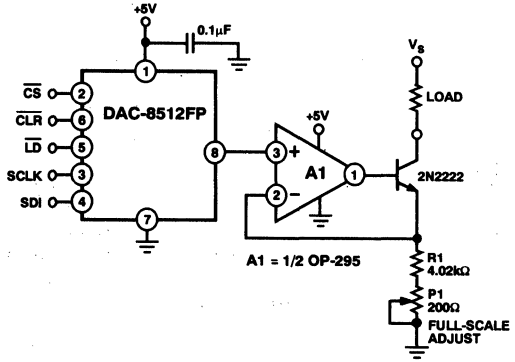

Figure 32. A Single-Supply, Programmable Current Source

The usable output voltage range of the current sink is +5 V to +60 V. The low limit of the range is controlled by transistor saturation, and the high limit is controlled by the collector-base breakdown voltage of the 2N2222.

A Digitally Programmable Window Detector

A digitally programmable, upper/lower limit detector using two DAC-8512s is shown in Figure 33. The required upper and lower limits for the test are loaded into each DAC individually by controlling HDAC/$\overline{LDAC}$. If a signal at the test input is not within the programmed limits, the output will indicate a logic zero which will turn the red LED on.

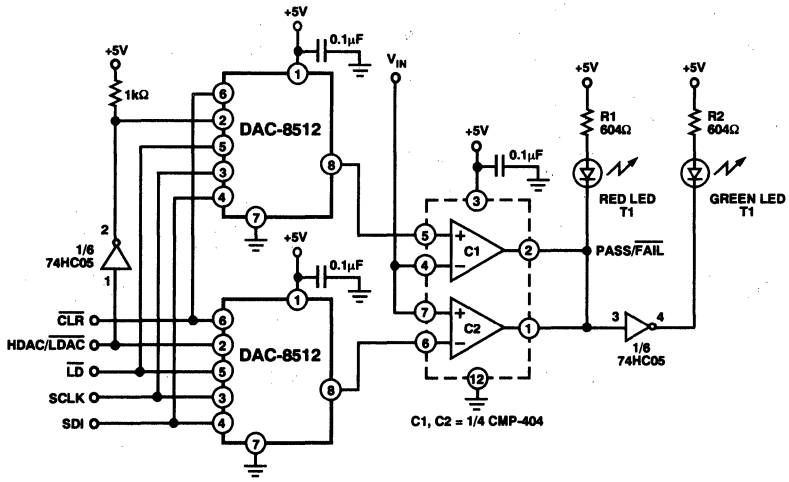

Figure 33. A Digitally Programmable Window Detector

Opto-Isolated Interfaces for Process Control Environments

In many process control type applications, it is necessary to provide an isolation barrier between the controller and the unit being controlled. Opto-isolators can provide isolation in excess of 3 kV. The serial loading structure of the DAC-8512 makes it ideal for optoisolated interfaces as the number of interface lines is kept to a minimum.

Illustrated in Figure 34 is an opto-isolated interface using the DAC-8512. In this circuit, the $\overline{CS}$ line is always LOW to enable the DAC, and the 10 kΩ/1 μF combination connected to the DAC's $\overline{CLR}$ pin sets a turn-on time constant of 10 ms to reset the DAC upon application of power. Three opto-couplers are then used for the SDI, SCLK, and $\overline{LD}$ lines.

Oftentimes reducing the number of interface lines to two lines is required in many control environments. The circuit illustrated in Figure 35 shows how to convert a two-line interface into the three control lines required to control the DAC-8512 without using one shots. This technique uses a counter to keep track of the clock cycles and, when all the data has been input to the DAC, the external logic generates the $\overline{LD}$ pulse.

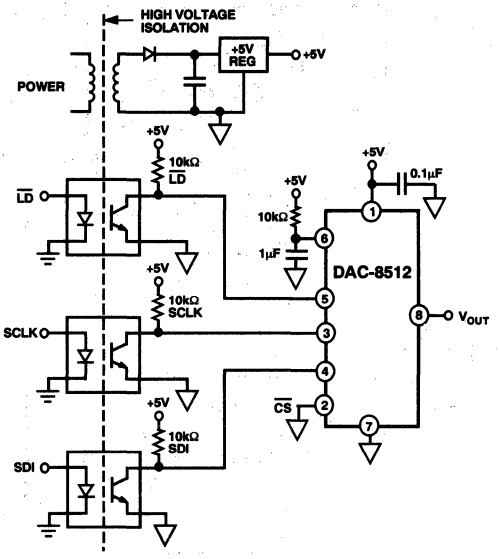

Figure 34. An Opto-Isolated DAC Interface

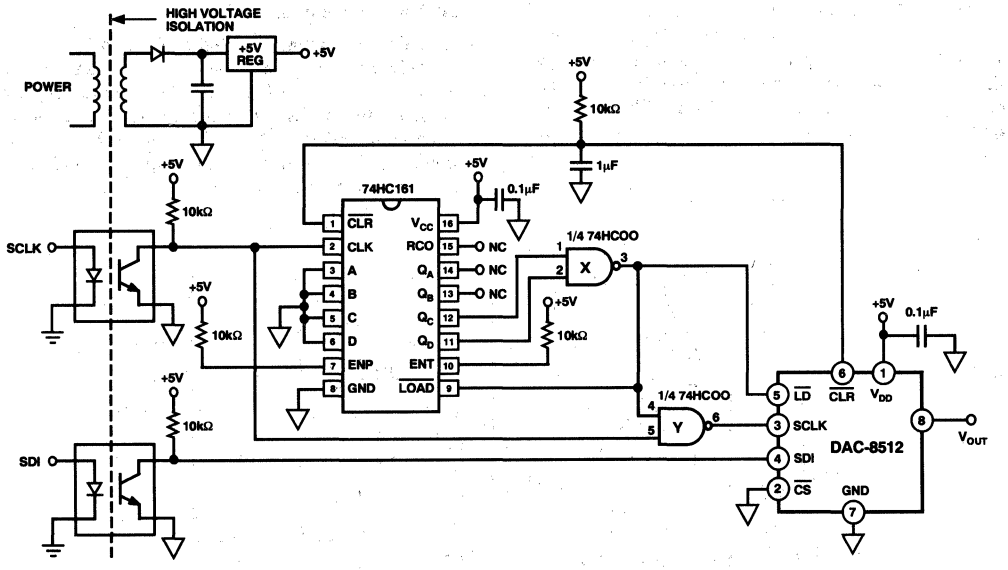

Figure 35. A Two-Wire, Opto-Isolated DAC Interface

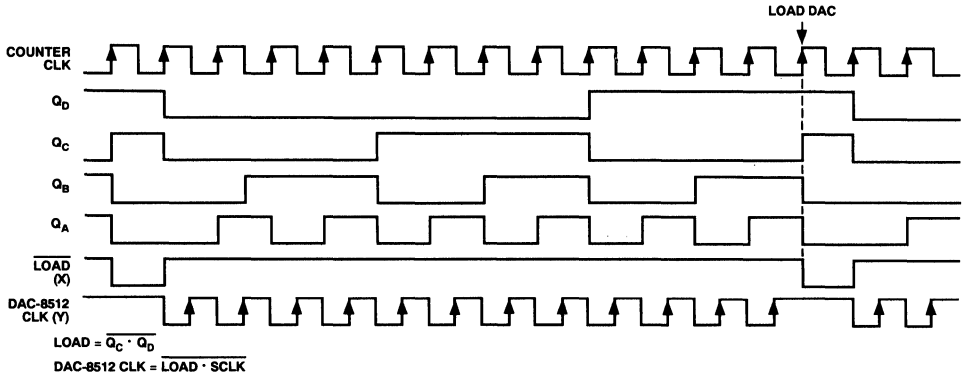

Figure 36. Opto-Isolated Two-Wire Serial Interface Timing Diagram

The timing diagram of Figure 36 can be used to understand the operation of the circuit. Only two opto-couplers are used in the circuit; one for SCLK and one for SDI. The 74HC161 counter in incremented on every rising edge of the clock. Additionally, the data is loaded into the DAC-8512 on the falling edge of the clock by inverting the serial clock using gate "Y." The timing diagram shows that after the twelfth bit has been clocked the output of the counter is binary 1011. On the very next rising clock edge, the output of the counter changes to binary 1100 upon which the output of gate "X" goes LOW to generate the $\overline{LD}$ pulse. The $\overline{LD}$ signal is connected to both the DAC's $\overline{LD}$ and the counter's LOAD pins to prevent the thirteenth rising clock edge from advancing the DAC's internal shift register. This prevents false loading of data into the DAC-8512. Inverting the DAC's serial clock allows sufficient time from the CLK edge to the $\overline{LD}$ edge, and from the $\overline{LD}$ edge to the next clock pulse all of which satisfies the timing requirements for loading the DAC-8512.

After loading one address of the DAC, the entire process can repeated to load another address. If the loading is complete, then the clock must stop after the thirteenth pulse of the final load. The DAC's clock input will be pulled high and the counter reset to zero. As was shown in Figure 35, both the 74HC161's and the DAC-8512's $\overline{CLR}$ pins are connected to a simple R-C timing circuit that resets both ICs when the power in turned on. The circuit's time constant should be set longer than the power supply turn-on time and, in this circuit, is set to 10 ms, which should be adequate for most systems. This same two-wire interface can be used for other three-wire serial input DACs.

Decoding Multiple DAC-8512s

The $\overline{CS}$ function of the DAC-8512 can be used in applications to decode a number of DACs. In this application, all DACs receive the same input data; however, only one of the DAC's $\overline{CS}$ input is asserted to transfer its serial input register contents into the destination DAC register. In this circuit, shown in Figure 37, the $\overline{CS}$ timing is generated by a 74HC139 decoder and should follow the DAC-8512's standard timing requirements. To prevent timing errors, the 74HC139 should not be activated by its ENABLE input while the coded address inputs are changing. A simple timing circuit, R1 and C1, connected to the DACs' $\overline{CLR}$ pins resets all DAC outputs to zero during power-up.

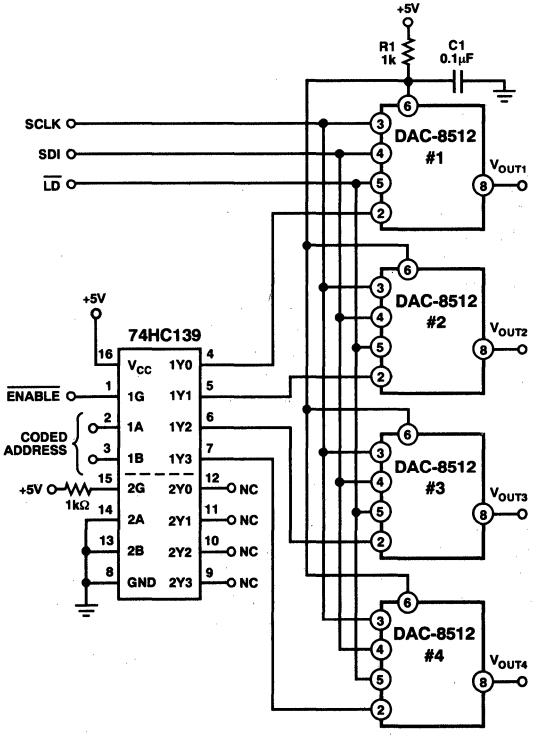

Figure 37. Decoding Multiple DAC-8512s Using the $\overline{CS}$ Pin

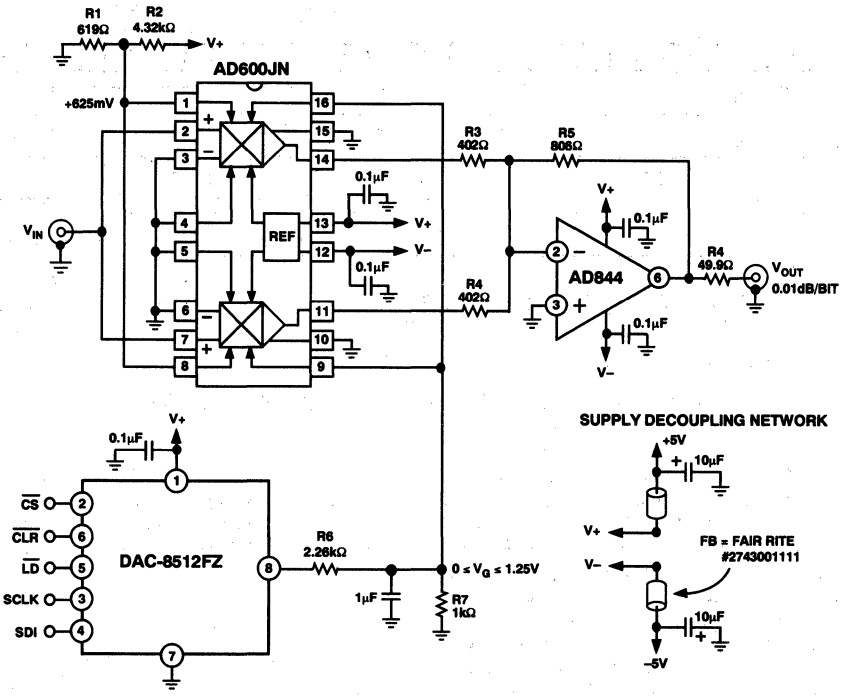

Figure 38. A Digitally Controlled, Ultralow Noise VCA

A Digitally Controlled, Ultralow Noise VCA

The circuit in Figure 38 illustrates how the DAC-8512 can be used to control an ultralow noise VCA, using the AD600/AD602. The AD600/AD602 is a dual, low noise, wideband, variable gain amplifier based on the X-AMP topology.* Both channels of the AD600 are wired in parallel to achieve a wideband VCA which exhibits an RTI (Referred To Input) noise voltage spectral density of approximately 1 nV/$\sqrt{\text{Hz}}$. The output of the VCA requires an AD844 configured in a gain of 4 to account for signal loss due to input and output 50-Ω terminations. As configured, the total gain in the circuit is 40 dB.

Since the output of the DAC-8512 is single quadrant, it was necessary to offset the AD600's gain control voltage so that the gain of the circuit is 0 dB for zero scale and 40 dB at full scale. This was achieved by setting C1LO and C2LO to + 625 mV using R1 and R2. Next, the output of the DAC-8512 was scaled so that the gain of the AD600 equalled 20 dB when the digital input code equaled 800_H. The frequency response of the VCA as a function of digital code is shown in Figure 39.

*For more details regarding the AD600 or AD602, please consult the AD600/AD602 data sheet.

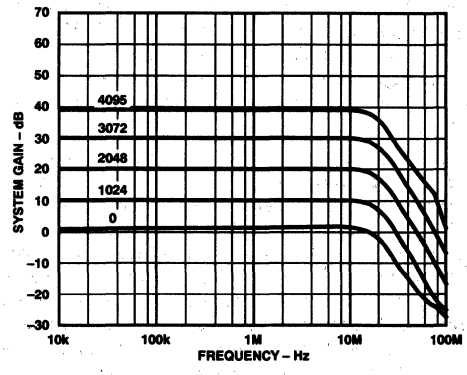

Figure 39. VCA Frequency Response vs. Digital Code

A Serial DAC, Audio Volume Control

The DAC-8512 is well suited to control digitally the gain or attenuation of a voltage controlled amplifier. In professional audio mixing consoles, music synthesizers, and other audio processors, VCAs, such as the SSM-2018, adjust audio channel gain and attenuation from front panel potentiometers. The VCA provides a clean gain transition control of the audio level when the slew rate of the analog input control voltage, V_C, is properly chosen. The circuit in Figure 40 illustrates a volume control application using the DAC-8512 to control the attenuation of the SSM-2018.

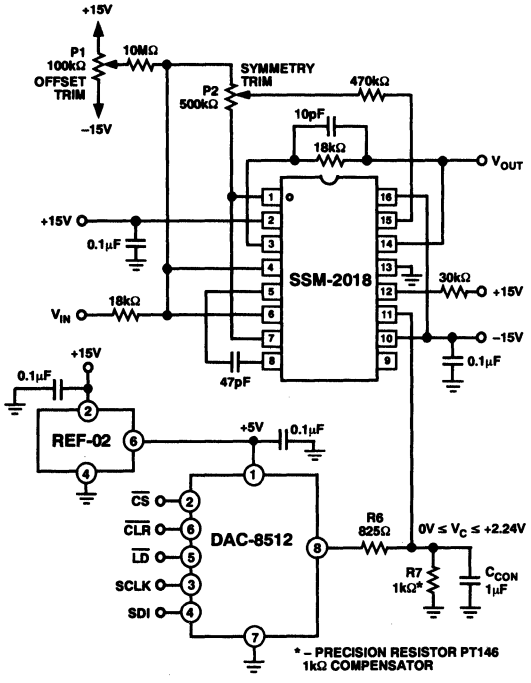

Figure 40. A Serial DAC, Audio Volume Control

Since the supply voltage available in these systems is typically ±15 V or ±18 V, a REF-02 is used to supply the +5 V required to power the DAC. No trimming of the reference is required because of the reference's tight initial tolerance and low supply current consumption of the DAC-8512. The SSM-2018 is configured as a unity-gain buffer when its control voltage equals 0 volt. This corresponds to a 000_H code from the DAC-8512. Since the SSM-2018 exhibits a gain constant of −28 mV/dB (typical), the DAC's full-scale output voltage has to be scaled down by R6 and R7 to provide 80 dB of attenuation when the digital code equals FFF_H. Therefore, every DAC LSB corresponds to 0.02 dB of attenuation. Table IV illustrates the attenuation vs. digital code of the volume control circuit.

Table IV. SSM-2018 VCA Attenuation vs. DAC-8512 Input Code

Hexadecimal Number in DAC Register	Control Voltage (V)	VCA Attenuation (dB)
000	0	0
400	+0.56	20
800	+1.12	40
C00	+1.68	60
FFF	+2.24	80

To compensate for the SSM-2018's gain constant temperature coefficient of −3300 ppm/°C, a 1 kΩ, temperature-sensitive resistor (R7) manufactured by the Precision Resistor Company with a temperature coefficient of +3500 ppm/°C is used. A C_{CON} of 1 μF provides a control transition time of 1 ms which yields a click-free change in the audio channel attenuation. Symmetry and offset trimming details of the VCA can be found in the SSM-2018 data sheet.

Information regarding the PT146 1 kΩ "Compensator" can be obtained by contacting:

An Isolated, Programmable, 4–20 mA Process Controller

In many process control system, applications, two-wire current transmitters are used to transmit analog signals through noisy environments. These current transmitters use a "zero-scale" signal current of 4 mA that can be used to power the transmitter's signal conditioning circuitry. The "full-scale" output signal in these transmitters is 20 mA. The converse approach to process control can also be used; a low-power, programmable current source can be used to control remotely located sensors or devices in the loop.

A circuit that performs this function is illustrated in Figure 41. Using the DAC-8512 as the controller, the circuit provides a programmable output current of 4 mA to 20 mA, proportional to the DAC's digital code. Biasing for the controller is provided by the REF-02 and requires no external trim for two reasons:

(1) the REF-02's tight initial output voltage tolerance and (2) the low supply current consumption of both the OP-90 and the DAC-8512. The entire circuit, including opto-couplers, consumes less than 3 mA from the total budget of 4 mA. The OP-90 regulates the output current to satisfy the current summation at the noninverting node of the OP-90. The KCL equation at Pin 3 is given by:

$$I_{OUT} = \frac{1}{R7} \times \left(\frac{1\,mV \times Digital\ Code \times R3}{R1} + \frac{V_{REF} \times R3}{R2} \right)$$

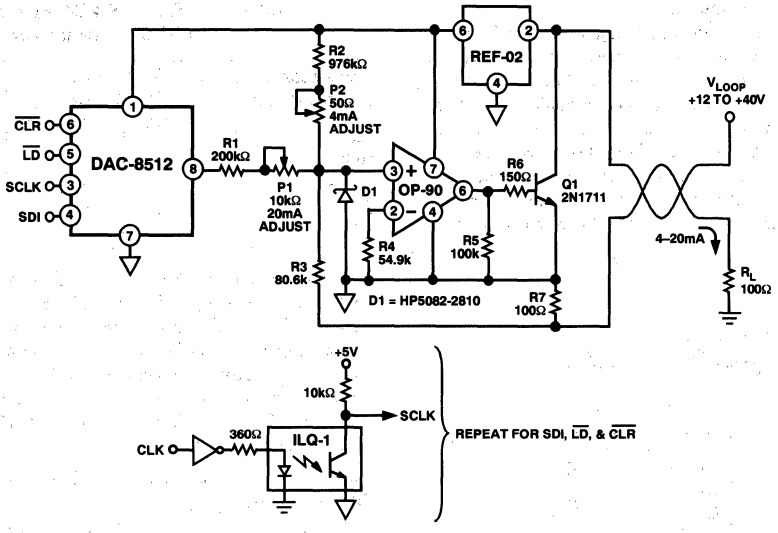

Figure 41. An Isolated, Programmable, 4–20 mA Process Controller

For the values shown in Figure 41,

$$I_{OUT} = 3.9\ \mu A \times Digital\ Code + 4\ mA$$

giving a full-scale output current of 20 mA when the DAC-8512's digital code equals FFF_H. Offset trim at 4 mA is provided by P2, and P1 provides the circuit's gain trim at 20 mA. These two trims do not interact because the noninverting input of the OP-90 is at virtual ground. The Schottky diode, D1, is required in this circuit to prevent loop supply power-on transients from pulling the noninverting input of the OP-90 more than 300 mV below its inverting input. Without this diode, such transients could cause phase reversal of the OP-90 and possible latchup of the controller. The loop supply voltage compliance of the circuit is limited by the maximum applied input voltage to the REF-02 and is from +12 V to +40 V.

MICROPROCESSOR INTERFACING

DAC-8512–MC68HC11 Interface

The circuit illustrated in Figure 42 shows a serial interface between the DAC-8512 and the MC68HC11 8-bit microcontroller. SCK of the 68HC11 drives SCLK of the DAC-8512, while the MOSI output drives the serial data line, SDI, of the DAC-8512. The DAC's $\overline{CLR}$, $\overline{LD}$, and $\overline{CS}$ signals are derived from port lines PC1, PD5, and PC0, respectively, as shown.

For correct operation of the serial interface, the 68HC11 should be configured such that its CPOL bit is set to 1 and its CPHA bit is also set to 1. When the serial data is to be transmitted to the DAC, PC0 is taken low, asserting the DAC's $\overline{CS}$ input. When the 68HC11 is configured in this manner, serial data on

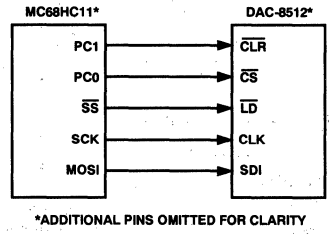

Figure 42. DAC-8512–MC68HC11 Interface

MOSI is valid on the rising edge of SCLK. The 68HC11 transmits its serial data in 8-bit bytes (MSB first), with only eight rising clock edges occurring in the transmit cycle. To load data to the DAC-8512's input serial register, PC0 is left low after the first eight bits are transferred, and a second byte of data is then transferred serially to the DAC-8512. During the second byte load, the first four most significant bits of the first byte are pushed out of the DAC's input shift register. At the end of the second byte load, PC0 is then taken high. To prevent an accidental advancing of the internal shift register, SCLK must already be asserted before PC0 is taken high. To transfer the contents of the input shift register to the DAC register, PD5 is taken low, asserting the DAC's $\overline{LD}$ input. The DAC's $\overline{CLR}$ input, controlled by the 68HC11's PC1 port, provides an asynchronous clear function, setting the DAC output to zero. Included in this section is the source code for operating the DAC-8512—M68HC11 interface.

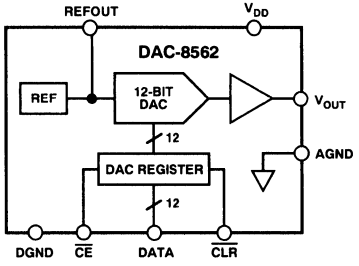
+5 Volt, Parallel Input Complete 12-Bit DAC

DAC8562

FEATURES
Complete 12-Bit DAC
No External Components
Single +5 Volt Operation
1 mV/Bit with 4.095 V Full Scale
True Voltage Output, ±5 mA Drive
Very Low Power −3 mW

APPLICATIONS
Digitally Controlled Calibration
Servo Controls
Process Control Equipment
PC Peripherals

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The DAC-8562 is a complete, parallel input, 12-bit, voltage output DAC designed to operate from a single +5 volt supply. Built using a CBCMOS process, these monolithic DACs offer the user low cost, and ease-of-use in +5 volt only systems.

Included on the chip, in addition to the DAC, is a rail-to-rail amplifier, latch and reference. The reference (REFOUT) is trimmed to 2.5 volts, and the on-chip amplifier gains up the DAC output to 4.095 volts full scale. The user needs only supply a +5 volt supply.

The DAC-8562 is coded straight binary. The op amp output swings from 0 to +4.095 volts for a one millivolt per bit resolution, and is capable of driving ±5 mA. Built using low temperature-coefficient silicon-chrome thin-film resistors, excellent linearity error over temperature has been achieved as shown below in the linearity error versus digital input code plot.

Digital interface is parallel and high speed to interface to the fastest processors without wait states. The interface is very simple requiring only a single $\overline{CE}$ signal. An asynchronous $\overline{CLR}$ input sets the output to zero scale.

The DAC-8562 is available in two different 20-pin packages, plastic DIP and SOL-20. Each part is fully specified for operation over −40°C to +85°C, and the full +5 V ± 5% power supply range.

For MIL-STD-883 applications, contact your local ADI sales office for the DAC-8562/883 data sheet which specifies operation over the −55°C to +125°C temperature range.

NOTES

[1]All input control signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.

[2]1 LSB=1 mV for 0 to +4.095 V output range.

[3]Includes internal voltage reference error.

[4]These parameters are guaranteed by design and not subject to production testing.

[5]Very little sink current is available at the REFOUT pin. Use external buffer if setting up a virtual ground.

[6]The settling time specification does not apply for negative going transitions within the last 6 LSBs of ground. Some devices exhibit double the typical settling time in this 6 LSB region.

Specifications subject to change without notice.

WAFER TEST LIMITS (@ V_{DD} = +5.0 V ± 5%, R_L = No Load, T_A = +25°C, applies to part number DAC8562GBC only, unless otherwise noted.)

Parameter	Symbol	Condition	Min	Typ	Max	Units

PIN DESCRIPTIONS

Pin	Name	Description
20	V_{DD}	Positive supply. Nominal value +5 volts, ±5%.
1–9 17–19	DB0–DB11	Twelve Binary Data Bit inputs. DB11 is the MSB and DB0 is the LSB.
16	$\overline{CE}$	Chip Enable. Active low input.
15	$\overline{CLR}$	Active low digital input that clears the DAC register to zero, setting the DAC to minimum scale.
8	DGND	Digital ground for input logic.
12	AGND	Analog Ground. Ground reference for the internal bandgap reference voltage, the DAC, and the output buffer.
13	V_{OUT}	Voltage output from the DAC. Fixed output voltage range of 0 V to 4.095 V with 1 mV/LSB. An internal temperature stabilized reference maintains a fixed full-scale voltage independent of time, temperature and power supply variations.
14	REFOUT	Nominal 2.5 V reference output voltage. This node must be buffered if required to drive external loads.
11	NC	No Connection. Leave pin floating.

OPERATION

The DAC-8562 is a complete ready to use 12-bit digital-to-analog converter. Only one +5 V power supply is necessary for operation. It contains a voltage-switched, 12-bit, laser-trimmed digital-to-analog converter, a curvature-corrected bandgap reference, a rail-to-rail output op amp, and a DAC register. The parallel data interface consists of 12 data bits, DB0–DB11, and a active low $\overline{CE}$ strobe. In addition, an asynchronous $\overline{CLR}$ pin will set all DAC register bits to zero causing the V_{OUT} to become zero volts. This function is useful for power on reset or system failure recovery to a known state.

D/A CONVERTER SECTION

The internal DAC is a 12-bit voltage-mode device with an output that swings from AGND potential to the 2.5 volt internal bandgap voltage. It uses a laser trimmed R-2R ladder which is switched by N channel MOSFETs. The output voltage of the DAC has a constant resistance independent of digital input code. The DAC output (not available to the user) is internally connected to the rail-to-rail output op amp.

AMPLIFIER SECTION

The internal DAC's output is buffered by a low power consumption precision amplifier. This low power amplifier contains a differential PNP pair input stage which provides low offset voltage and low noise, as well as the ability to amplify the zero-scale DAC output voltages. The rail-to-rail amplifier is configured in a gain of 1.6384 (= 4.095 V/2.5 V) in order to set the 4.095 volt full-scale output (1 mV/LSB). See Figure 3 for an equivalent circuit schematic of the analog section.

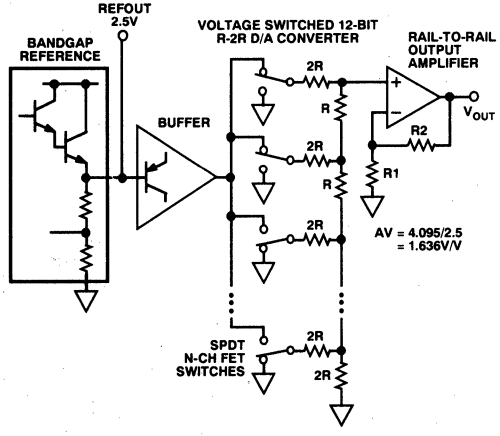

Figure 3. Equivalent DAC-8562 Schematic of Analog Portion

The op amp has a 16 μs typical settling time to 0.01%. There are slight differences in settling time for negative slewing signals versus positive. See the oscilloscope photos in the Typical Performances section of this data sheet.

OUTPUT SECTION

The rail-to-rail output stage of this amplifier has been designed to provide precision performance while operating near either power supply. Figure 4 shows an equivalent output schematic of the rail-to-rail amplifier with its N channel pull down FETs that will pull an output load directly to GND. The output sourcing current is provided by a P channel pull-up device that can supply GND terminated loads, especially important at the −5% supply tolerance value of 4.75 volts.

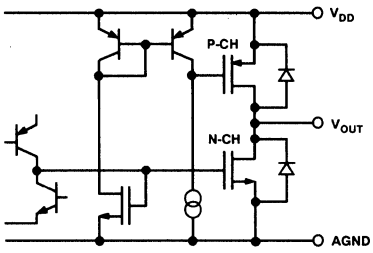

Figure 4. Equivalent Analog Output Circuit

Figures 5 and 6 in the typical performance characteristics section provide information on output swing performance near ground and full scale as a function of load. In addition to resistive load driving capability, the amplifier has also been carefully designed and characterized for up to 500 pF capacitive load driving capability.

REFERENCE SECTION

The internal 2.5 V curvature-corrected bandgap voltage reference is laser trimmed for both initial accuracy and low temperature coefficient. The voltage generated by the reference is available at the REFOUT pin. Since REFOUT is *not* intended to drive external loads, it must be buffered—refer to the applications section for more information. The equivalent emitter follower output circuit of the REFOUT pin is shown in Figure 3.

Bypassing the REFOUT pin is not required for proper operation. Figure 7 shows broadband noise performance.

POWER SUPPLY

The very low power consumption of the DAC-8562 is a direct result of a circuit design optimizing use of the CBCMOS process. By using the low power characteristics of the CMOS for the logic, and the low noise, tight matching of the complementary bipolar transistors, good analog accuracy is achieved.

For power-consumption sensitive applications it is important to note that the internal power consumption of the DAC-8562 is strongly dependent on the actual logic-input voltage-levels present on the DB0–DB11, $\overline{CE}$ and $\overline{CLR}$ pins. Since these inputs are standard CMOS logic structures, they contribute static power dissipation dependent on the actual driving logic V_{OH} and V_{OL} voltage levels. The graph in Figure 9 shows the effect on total DAC-8562 supply current as a function of the actual value of input logic voltage. Consequently for optimum dissipation use of CMOS logic versus TTL provides minimal dissipation in the static state. A V_{INL} = 0 V on the DB0–DB11 pins provides the lowest standby dissipation of 600 μA with a +5 V power supply.

As with any analog system, it is recommended that the DAC-8562 power supply be bypassed on the same PC card that contains the chip. Figure 10 shows the power supply rejection versus frequency performance. This should be taken into account when using higher frequency switched-mode power supplies with ripple frequencies of 100 kHz and higher.

One advantage of the rail-to-rail output amplifier used in the DAC-8562 is the wide range of usable supply voltage. The part is fully specified and tested over temperature for operation from +4.75 V to +5.25 V. If reduced linearity and source current capability near full scale can be tolerated, operation of the DAC-8562 is possible down to +4.3 volts. The minimum operating supply voltage versus load current plot, in Figure 11, provides information for operation below V_{DD} = +4.75 V.

TIMING AND CONTROL

The DAC-8562 has a 12-bit DAC register that simplifies interface to a 12-bit (or wider) data bus. The latch is controlled by the Chip Enable ($\overline{CE}$) input. If the application does not involve a data bus, wiring $\overline{CE}$ low allows direct operation of the DAC.

The data latch is level triggered and acquires data from the data bus during the time period when $\overline{CE}$ is low. When $\overline{CE}$ goes high, the data is latched into the register and held until $\overline{CE}$ returns low. The minimum time required for the data to be present on the bus before $\overline{CE}$ returns high is called the data setup time (t_{DS}) as seen in Figure 2. The data hold time (t_{DH}) is the amount of time that the data has to remain on the bus after $\overline{CE}$ goes high. The high speed timing offered by the DAC-8562 provides for direct interface with no wait states in all but the fastest microprocessors.

APPLICATIONS SECTION

Power Supplies, Bypassing, and Grounding

All precision converter products require careful application of good grounding practices to maintain full-rated performance. Because the DAC-8562 has been designed for +5 V applications, it is ideal for those applications under microprocessor or microcomputer control. In these applications, digital noise is prevalent; therefore, special care must be taken to assure that its inherent precision is maintained. This means that particularly good engineering judgment should be exercised when addressing the power supply, grounding, and bypassing issues using the DAC-8562.

The power supply used for the DAC-8562 should be well filtered and regulated. The device has been completely characterized for a +5 V supply with a tolerance of ±5 %. Since a +5 V logic supply is almost universally available, it is not recommended to connect the DAC directly to an unfiltered logic supply without careful filtering. Because it is convenient, a designer might be inclined to tap a logic circuit's supply for the DAC's supply. Unfortunately, this is not wise because fast logic with nanosecond transition edges induces high current pulses. The high transient current pulses can generate glitches hundreds of millivolts in amplitude due to wiring resistances and inductances. This high frequency noise will corrupt the analog circuits internal to the DAC and cause errors. Even though their spike noise is lower in amplitude, directly tapping the output of a +5 V system supplies can cause errors because these supplies are of the switching regulator type that can and do generate a great deal of high frequency noise. Therefore, the DAC and any associated analog circuitry should be powered directly from the system power supply outputs using appropriate filtering. Figure 28 illustrates how a clean, analog-grade supply can be generated from a +5 V logic supply using a differential LC filter with separate power supply and return lines. With the values shown, this filter can easily handle 100 mA of load current without saturating the ferrite cores. Higher current capacity can be achieved with larger ferrite cores. For lowest noise, all electrolytic capacitors should be low ESR (Equivalent Series Resistance) type.

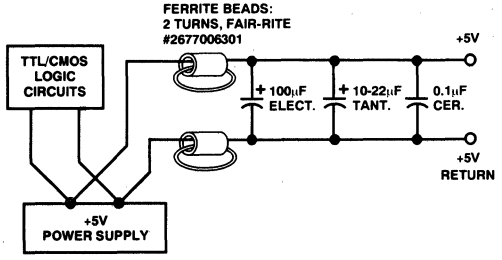

Figure 28. Properly Filtering a +5 V Logic Supply Can Yield a High Quality Analog Supply

The DAC-8562 includes two ground connections in order to minimize system accuracy degradation arising from grounding errors. The two ground pins are designated DGND (Pin 10) and AGND (Pin 12). The DGND pin is the return for the digital circuit sections of the DAC and serves as their input threshold reference point. Thus DGND should be connected to the same ground as the circuitry that drives the digital inputs.

Pin 12, AGND, serves as the supply rail for the internal voltage reference and the output amplifier. This pin should also serve as the reference point for all analog circuitry associated with the DAC-8562. Therefore, to minimize any errors, it is recommended that the AGND connection of the DAC-8562 be connected to a high quality analog ground. If the system contains any analog signal path carrying a significant amount of current, then that path should have its own return connection to Pin 12.

It is often advisable to maintain separate analog and digital grounds throughout a complete system, tying them common to one place only. If the common tie point is remote and an accidental disconnection of that one common tie point were to occur due to card removal with power on, a large differential voltage between the two commons could develop. To protect devices that interface to both digital and analog parts of the system, such as the DAC-8562, it is recommended that the common ground tie points be provided at each such device. If only one system ground can be connected directly to the DAC-8562, it recommended that the analog common be used. If the system's AGND has suitably low impedance, then the digital signal currents flowing in it should not seriously affect the ground noise. The amount of digital noise introduced by connecting the two grounds together at the device will not adversely affect system performance due to loss of digital noise immunity.

Generous bypassing of the DAC's supply goes a long way in reducing supply line-induced errors. Local supply bypassing consisting of a 10 µF tantalum electrolytic in parallel with a 0.1 µF ceramic is recommended. The decoupling capacitors should be connected between the DAC's supply pin (Pin 20) and the analog ground (Pin 12). Figure 29 shows how the DGND, AGND, and bypass connections should be made to the DAC-8562.

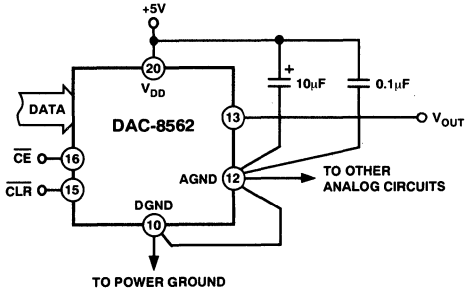

Figure 29. Recommended Grounding and Bypassing Scheme for the DAC-8562

Unipolar Output Operation

This is the basic mode of operation for the DAC-8562. As shown in Figure 30, the DAC-8562 has been designed to drive loads as low as 820 Ω in parallel with 500 pF. The code table for this operation is shown in Table III.

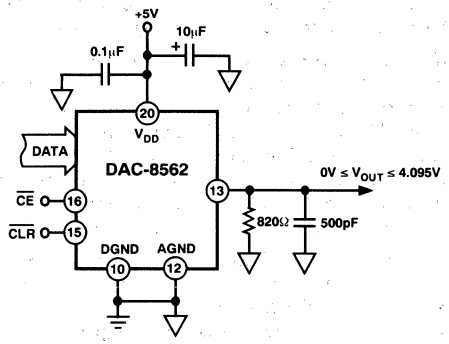

Figure 30. Unipolar Output Operation

Table III. Unipolar Code Table

Hexadecimal Number in DAC Register	Decimal Number in DAC Register	Analog Output Voltage (V)
FFF	4095	+4.095
801	2049	+2.049
800	2048	+2.048
7FF	2047	+2.047
000	0	0

Operating the DAC-8562 on +12 V or +15 V Supplies Only

Although the DAC-8562 has been specified to operate on a single, +5 V supply, a single +5 V supply may not be available in many applications. Since the DAC-8562 consumes no more than 6 mA, maximum, then an integrated voltage reference, such as the REF-02, can be used as the DAC-8562 +5 V supply. The configuration of the circuit is shown in Figure 31. Notice that the reference's output voltage requires no trimming because of the REF-02's excellent load regulation and tight initial output voltage tolerance. Although the maximum supply current of the DAC-8562 is 6 mA, local bypassing of the REF-02's output with at least 0.1 µF at the DAC's voltage supply pin is recommended to prevent the DAC's internal digital circuits from affecting the DAC's internal voltage reference.

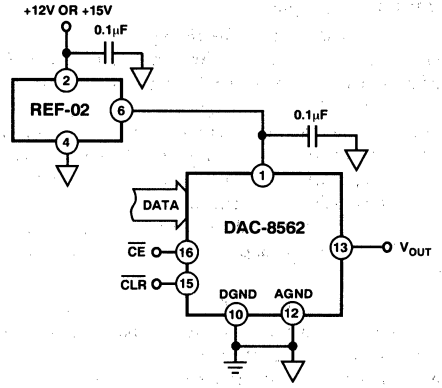

Figure 31. Operating the DAC-8562 on +12 V or +15 V Supplies Using a REF-02 Voltage Reference

Measuring Offset Error

One of the most commonly specified endpoint errors associated with real-world nonideal DACs is offset error.

In most DAC testing, the offset error is measured by applying the zero-scale code and measuring the output deviation from 0 volt. There are some DACs where offset errors may be present but not observable at the zero scale because of other circuit limitations (for example, zero coinciding with single supply ground). In these DACs, nonzero output at zero code cannot be read as the offset error. In the DAC-8562, for example, the zero-scale error is specified to be +3 LSBs. Since zero scale coincides with zero volt, it is not possible to measure negative offset error.

By adding a pull-down resistor from the output of the DAC-8562 to a negative supply as shown in Figure 32, offset errors can now be read at zero code. This configuration forces the output P-channel MOSFET to source current to the negative supply thereby allowing the designer to determine in which direction the offset error appears. The value of the resistor should be such that, at zero code, current through the resistor is 200 µA maximum.

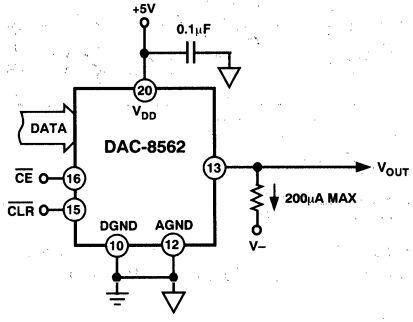

Figure 32. Measuring Zero-Scale or Offset Error

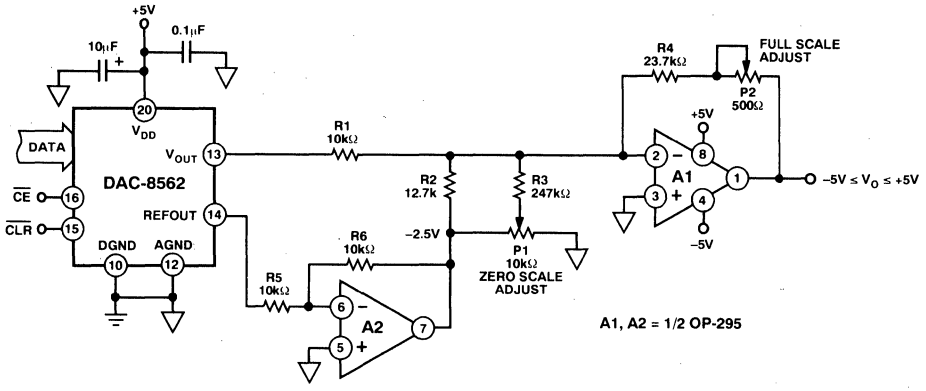

Figure 33. Bipolar Output Operation

Bipolar Output Operation

Although the DAC-8562 has been designed for single supply operation, bipolar operation is achievable using the circuit illustrated in Figure 33. The circuit uses a single supply, rail-to-rail OP-295 op amp and the DAC's internal +2.5 V reference to generate the −2.5 V reference required to level-shift the DAC output voltage. The circuit has been configured to provide an output voltage in the range $-5\ V \le V_{OUT} \le +5\ V$ and is coded in complementary offset binary. Although each DAC LSB corresponds to 1 mV, each output LSB has been scaled to 2.44 mV. Table IV provides the relationship between the digital codes and output voltage.

The transfer function of the circuit is given by:

$$V_O = -1\ mV \times Digital\ Code \times \left(\frac{R4}{R1}\right) + 2.5 \times \left(\frac{R4}{R2}\right)$$

and, for the circuit values shown, becomes:

$$V_O = -2.44\ mV \times Digital\ Code + 5\ V$$

Table IV. Bipolar Code Table

Hexadecimal Number in DAC Register	Decimal Number in DAC Register	Analog Output Voltage (V)
FFF	4095	−4.9976
801	2049	−2.44E−3
800	2048	0
7FF	2047	+2.44E−3
000	0	+5

To maintain monotonicity and accuracy, R1, R2, R4, R5, and R6 should be selected to match within 0.01% and must all be of the same (preferably metal foil) type to assure temperature coefficient matching. Mismatching between R1 and R2 causes offset and gain errors while an R4 to R1 and R2 mismatch yields gain errors.

For applications that do not require high accuracy, the circuit illustrated in Figure 34 can also be used to generate a bipolar output voltage. In this circuit, only one op amp is used and no potentiometers are used for offset and gain trim. The output voltage is coded in offset binary and is given by:

$$V_O = 1\ mV \times Digital\ Code \times \left(\frac{R4}{R3 + R4}\right) \times \left(1 + \frac{R2}{R1}\right) - REFOUT \times \left(\frac{R2}{R1}\right)$$

For the ±2.5 V output range and the circuit values shown in the table, the transfer equation becomes:

$$V_O = 1.22\ mV \times Digital\ Code - 2.5\ V$$

Similarly, for the ±5 V output range, the transfer equation becomes:

$$V_O = 2.44\ mV \times Digital\ Code - 5\ V$$

Note that, for ±5 V output voltage operation, R5 is required as a pull-down for REFOUT. Or, REFOUT can be buffered by an op amp configured as a follower that can source and sink current.

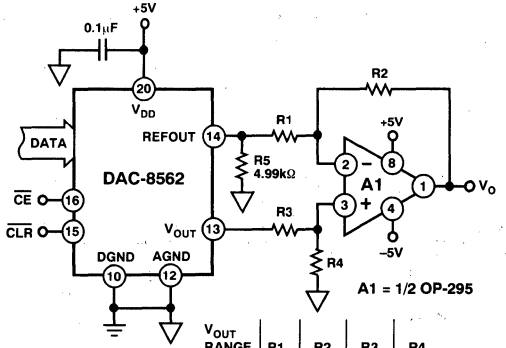

Figure 34. Bipolar Output Operation Without Trim Version 1

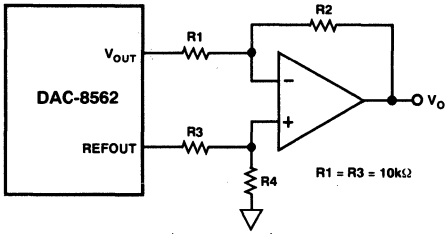
Alternatively, the output voltage can be coded in complementary offset binary using the circuit in Figure 35. This configuration eliminates the need for a pull-down resistor or an op amp for

REFOUT. The transfer equation of the circuit is given by:

$$V_O = -1\ mV \times Digital\ Code \times \left(\frac{R2}{R1}\right) + REFOUT \times \left(\frac{R4}{R3 + R4}\right) \times \left(1 + \frac{R2}{R1}\right)$$

and, for the values shown, becomes:

$$V_O = -2.44\ mV \times Digital\ Code + 5\ V$$



V_O RANGE	R2	R4
±5V	23.7k + 715	13.7k + 169Ω

Figure 35. Bipolar Output Operation Without Trim Version 2

Generating a Negative Supply Voltage

Some applications may require bipolar output configuration, but only have a single power supply rail available. This is very common in data acquisition systems using microprocessor-based systems. In these systems, only +12 V, +15 V, and/or +5 V are available. Shown in Figure 36 is a method of generating a negative supply voltage using one CD4049, a CMOS hex inverter, operating on +12 V or +15 V. The circuit is essentially a charge pump where two of the six are used as an oscillator. For the values shown, the frequency of oscillation is approximately 3.5 kHz and is fairly insensitive to supply voltage because R1 > 2 × R2. The remaining four inverters are wired in parallel for higher output current. The square-wave output is level translated by C2 to a negative-going signal, rectified using a pair of 1N4001s, and then filtered by C3. With the values shown, the charge pump will provide an output voltage of −5 V for current loading in the range 0.5 mA ≤ I_{OUT} ≤ 10 mA with a +15 V supply and 0.5 mA ≤ I_{OUT} ≤ 7 mA with a +12 V supply.

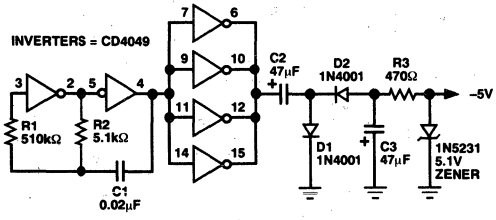


Figure 36. Generating a −5 V Supply When Only +12 V or +15 V Are Available

Audio Volume Control

The DAC-8562 is well suited to control digitally the gain or attenuation of a voltage controlled amplifiers. In professional audio mixing consoles, music synthesizers, and other audio processors, VCAs, such as the SSM-2018, adjust audio channel gain and attenuation from front panel potentiometers. The VCA provides a clean gain transition control of the audio level when the slew rate of the analog input control voltage, V_C, is properly chosen. The circuit in Figure 37 illustrates a volume control application using the DAC-8562 to control the attenuation of the SSM-2018.

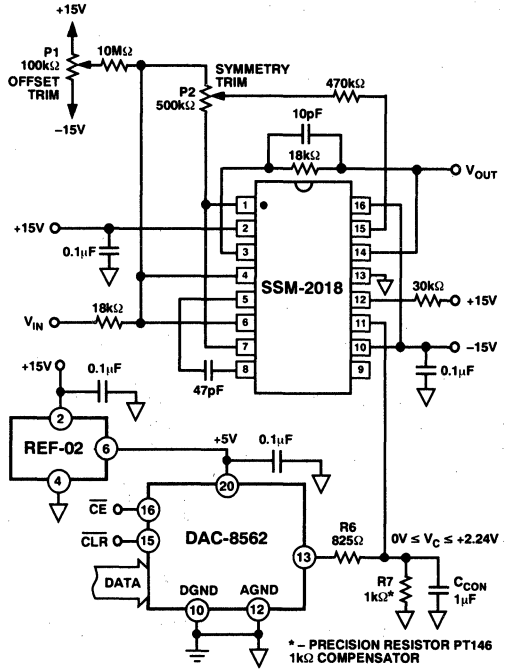

Figure 37. Audio Volume Control

Since the supply voltage available in these systems is typically ±15 V or ±18 V, a REF-02 is used to supply the +5 V required to power the DAC. No trimming of the reference is required because of the reference's tight initial tolerance and low supply current consumption of the DAC-8562. The SSM-2018 is configured as a unity-gain buffer when its control voltage equals 0 volt. This corresponds to a 000_H code from the DAC-8562. Since the SSM-2018 exhibits a gain constant of −28 mV/dB (typical), the DAC's full-scale output voltage has to be scaled down by R6 and R7 to provide 80 dB of attenuation when the digital code equals FFF_H. Therefore, every DAC LSB corresponds to 0.02 dB of attenuation. Table V illustrates the attenuation versus digital code of the volume control circuit.

Table V. SSM-2018 VCA Attenuation vs. DAC-8562 Input Code

Hexadecimal Number in DAC Register	Control Voltage (V)	VCA Attenuation (dB)
000	0	0
400	+0.56	20
800	+1.12	40
C00	+1.68	60
FFF	+2.24	80

To compensate for the SSM-2018's gain constant temperature coefficient of –3300 ppm/°C, a 1 kΩ, temperature-sensitive resistor (R7) manufactured by the Precision Resistor Company with a temperature coefficient of +3500 ppm/°C is used. A C_{CON} of 1 μF provides a control transition time of 1 ms which yields a click-free change in the audio channel attenuation. Symmetry and offset trimming details of the VCA can be found in the SSM-2018 data sheet.

A High-Compliance, Digitally Controlled Precision Current Source

The circuit in Figure 38 shows the DAC-8562 controlling a high-compliance, precision current source using an AMP-05 instrumentation amplifier. The AMP-05's reference pin becomes the input, and the "old" inputs now monitor the voltage across a precision current sense resistor, R_{CS}. Voltage gain is set to unity, so the transfer function is given by the following equation:

$$I_{OUT} = \frac{V_{IN}}{R_{CS}}$$

If R_{CS} equals 100 Ω, the output current is limited to +10 mA with a 1 V input. Therefore, each DAC LSB corresponds to 2.4 μA. If a bipolar output current is required, then the circuit in Figure 33 can be modified to drive the AMP-05's reference pin with a ±1 V input signal.

Potentiometer P1 trims the output current to zero with the input at 0 V. Fine gain adjustment can be accomplished by adjusting R1 or R2.

A Digitally Programmable Window Detector

A digitally programmable, upper/lower limit detector using two DAC-8562s is shown in Figure 39. The required upper and lower limits for the test are loaded into each DAC individually by controlling HDAC/$\overline{\text{LDAC}}$. If a signal at the test input is not within the programmed limits, the output will indicate a logic zero which will turn the red LED on.

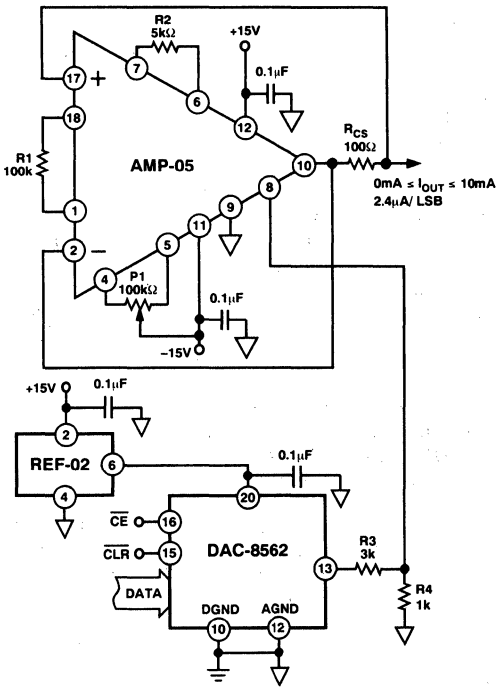

Figure 38. A High-Compliance, Digitally Controlled Precision Current Source

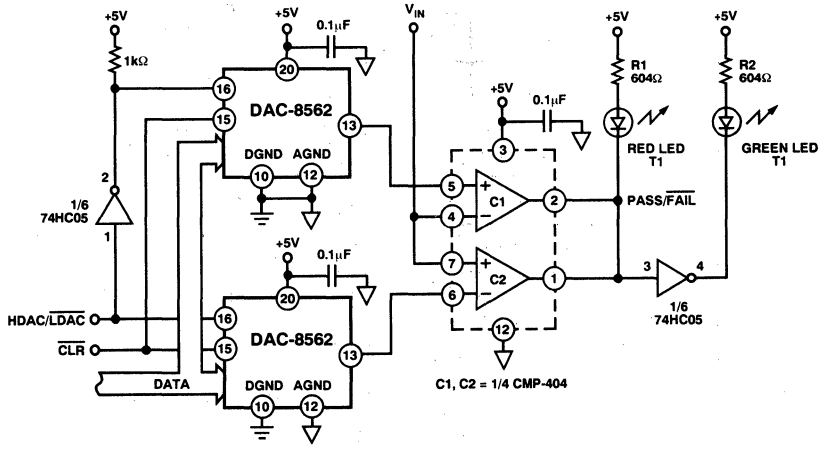

Figure 39. A Digitally Programmable Window Detector

Decoding Multiple DAC-8562s

The $\overline{CE}$ function of the DAC-8562 can be used in applications to decode a number of DACs. In this application, all DACs receive the same input data; however, only one of the DACs' $\overline{CE}$ input is asserted to transfer its parallel input register contents into the DAC. In this circuit, shown in Figure 40, the $\overline{CE}$ timing is generated by a 74HC139 decoder and should follow the DAC-8562's standard timing requirements. To prevent timing errors, the 74HC139 should not be activated by its $\overline{ENABLE}$ input while the coded address inputs are changing. A simple timing circuit, R1 and C1, connected to the DACs' $\overline{CLR}$ pins resets all DAC outputs to zero during power-up.

MICROPROCESSOR INTERFACING

DAC-8562-MC68HC11 Interface

The circuit illustrated in Figure 41 shows a parallel interface between the DAC-8562 and a popular 8-bit microcontroller, the M68HC11, which is configured in a single-chip operating mode. The interface circuit consists of a pair of 74ACT11373 transparent latches and an inverter. The data is loaded into the latches in two 8-bit bytes; the first byte contains the four most significant bits, and the lower 8 bits are in the second byte. Data is taken from the microcontroller's port B output lines, and three interface control lines, $\overline{CLR}$, $\overline{CE}$, and MSB/$\overline{LSB}$, are controlled by the M68HC11's PC2, PC1, and PC0 output lines, respectively. To transfer data into the DAC, PC0 is set, enabling U1's outputs. The first data byte is loaded into U1 where the four least significant bits of the byte are connected to MSB–DB8. PC0 is then cleared; this latches U1's inputs and enables U2's outputs. U2s outputs now become DB7–DB0. The DAC output is updated with the contents of U1 and U2 when PC1 is cleared. The DAC's $\overline{CLR}$ input, controlled by the M68HC11's PC2 output line, provides an asynchronous clear function that sets the DAC's output to zero. Included in this section is the source code for operating the DAC-8562–M68HC11 interface.

Octal 8-Bit CMOS D/A Converter

DAC8800

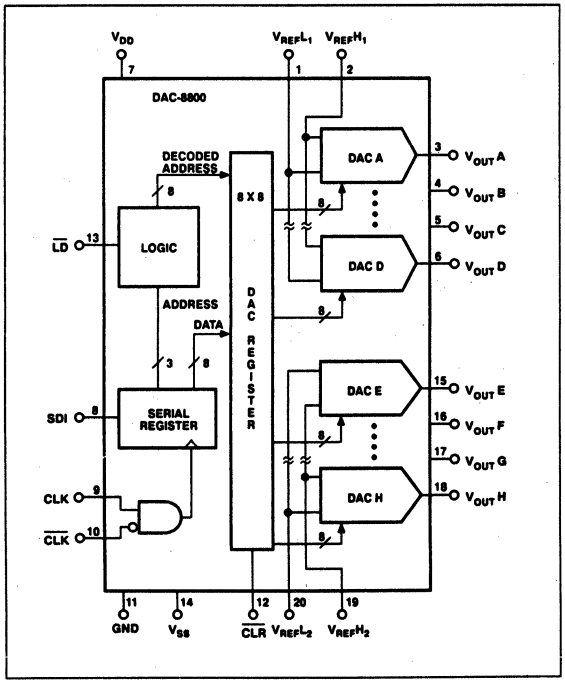
FEATURES

- ±1/2 LSB Total Unadjusted Error
- 2μs Settling Time
- Serial Data Input
- ±Full-Scale Output Set by $V_{REF}H$ and $V_{REF}L$
- Unipolar and Bipolar Operation
- TTL Input Compatible
- 20-Pin DIP or SOL Package
- Low Cost

APPLICATIONS

- Voltage Set Point Control
- Digital Offset & Gain Adjustment
- Microprocessor Controlled Calibration
- General Purpose Trimming Adjustments

FUNCTIONAL DIAGRAM



GENERAL DESCRIPTION

The DAC-8800 TrimDAC™ is designed to be a general purpose digitally controlled voltage adjustment device. The output voltage range can be independently set for each set of four D/A converters. In addition, both unipolar and bipolar output voltage ranges are easy to establish by external reference input high and low terminals. The digitally-programmed output voltages are ideal for op amp trimming, voltage-controlled amplifier gain setting and any general purpose trimming tasks.

A three-wire serial digital interface loads the contents of eight internal DAC registers which establish the output voltage levels. An asynchronous Clear ($\overline{CLR}$) input places all DACs in a zero code output condition, very handy for system power-up. An internal regulator provides TTL input compatibility over a wide range of V_{DD} supply voltages. Single supply operation is available by connecting V_{SS} to GND.

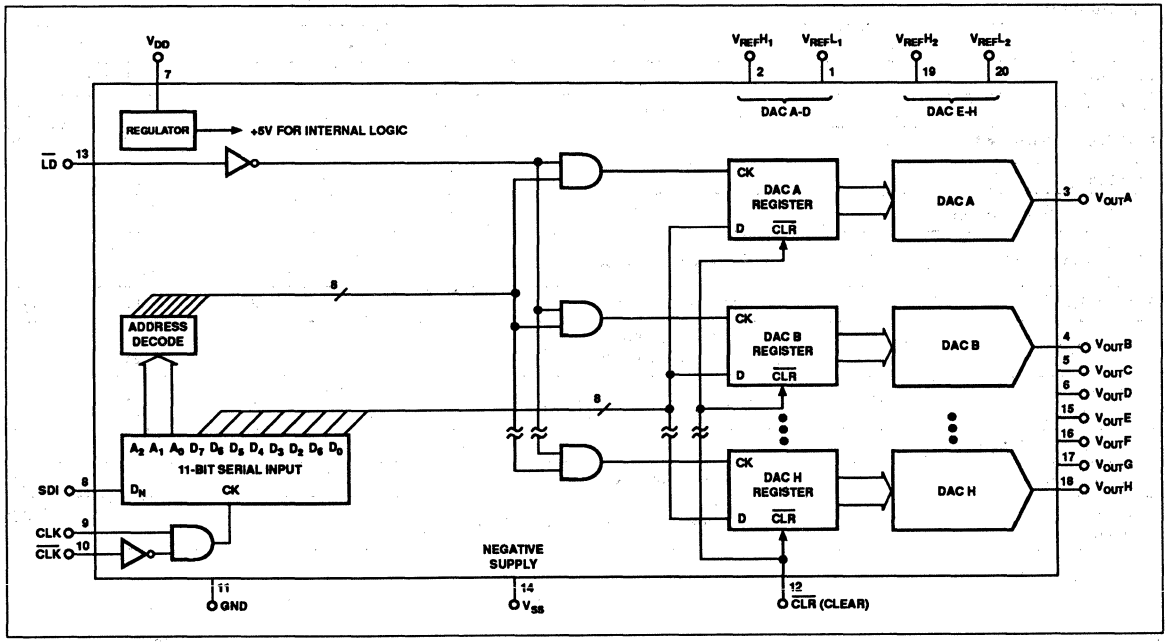
Clock Edge to Load Time	t_{CKLD}		50	–	–	ns
Load Edge to Next Clock Edge Time	t_{LDCK}		50	–	–	ns

NOTES:
1. Testing performed in SINGLE SUPPLY mode, except I_{DD}, I_{SS}, and PSRR which are tested in DUAL SUPPLY mode.
2. Includes Full Scale Error, Relative Accuracy, and Zero Code Error.
3. All devices guaranteed monotonic over the full operating temperature range.
4. Guaranteed by design and not subject to production test.
5. V_{DD} – 4 volts is the maximum reference voltage for the above specifications. Also $V_{REF}H \geq V_{REF}L$.
6. Digital Input voltages $V_{IN} = V_{INL}$ or V_{INH} for TTL condition; V_{IN} = 0V or +5V for CMOS condition. DAC outputs unloaded. P_{DISS} is calculated from $(I_{DD} \times V_{DD}) + (I_{SS} \times V_{SS})$.
7. Measured at V_{OUT} pin where an adjacent V_{OUT} pin is making a full-scale voltage change.
8. See timing diagram for location of measured values.

DETAILED DAC-8800 BLOCK DIAGRAM



8-Bit, Octal, 4-Quadrant Multiplying, CMOS TrimDAC

DAC8840

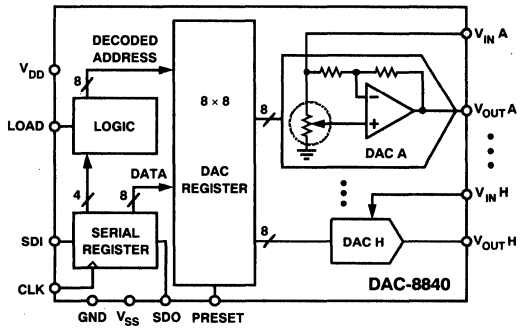
FEATURES

Replaces 8 Potentiometers
1 MHz 4-Quadrant Multiplying Bandwidth
No Signal Inversion
Low Zero Output Error
Eight Individual Channels
3-Wire Serial Input
500 kHz Update Data Loading Rate
±3 Volt Output Swing
Midscale Preset, Zero Volts Out

APPLICATIONS

Automatic Adjustment
Trimmer Replacement
Dynamic Level Adjustment
Special Waveform Generation and Modulation

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The DAC-8840 provides eight general purpose digitally controlled voltage adjustment devices. The TrimDAC® capability allows replacement of the mechanical trimmer function in new designs. The DAC-8840 is ideal for ac or dc gain control of up to 1 MHz bandwidth signals. The 4-quadrant multiplying capability is useful for signal inversion and modulation often found in video convergence circuitry.

Internally the DAC-8840 contains eight voltage output CMOS digital-to-analog converters, each with separate reference inputs. Each DAC has its own DAC register which holds its output state. These DAC registers are updated from an internal serial-to-parallel shift register which is loaded from a standard 3-wire serial input digital interface. Twelve data bits make up the data word clocked into the serial input register. This data word is decoded where the first 4 bits determine the address of the DAC register to be loaded with the last 8 bits of data. A serial data output pin at the opposite end of the serial register allows simple daisy-chaining in multiple DAC applications without additional external decoding logic.

TrimDAC is a registered trademark of Analog Devices, Inc.

The DAC-8840 consumes only 190 mW from ±5 V power supplies. For single 5 V supply applications consult the DAC-8841.

The DAC-8840 is available in 24-pin plastic DIP, cerdip, and SOIC-24 packages.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

DAC8840—SPECIFICATIONS (V_{DD} = +5 V, V_{SS} = −5 V, All $V_{IN}X$ = +3 V, T_A = −40°C to +85°C apply for DAC-8840F, unless otherwise noted)

Parameter	Symbol	Conditions	Min	Typ	Max	Units

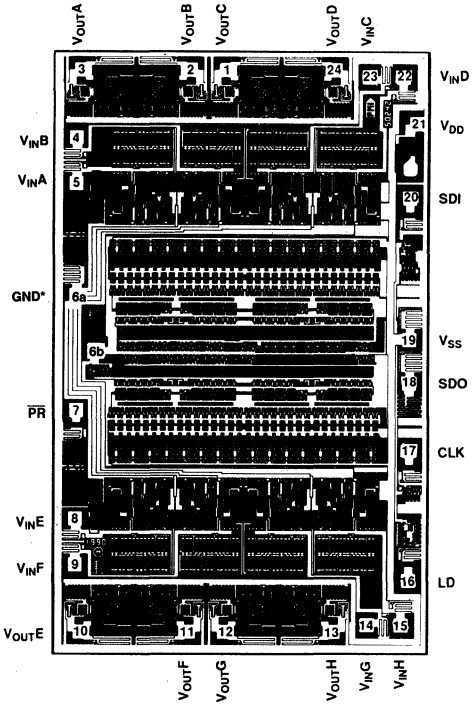
DICE CHARACTERISTICS

DIE SIZE 0.117 × 0.185 inch, 21,645 sq. mils
(2.9718 × 4.699 mm, 13.964 sq. mm)
The die backside is electrically common to V_{DD}.
The DAC8840 contains 3236 transistors.



*BOTH GND PADS (6a, 6b) ARE BONDED TO PIN 6 OF PACKAGE.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

Integrated Circuit Voltage-to-Frequency Converter

AD537*

FEATURES

- Low Cost A-D Conversion
- Versatile Input Amplifier
  - Positive or Negative Voltage Modes
  - Negative Current Mode
  - High Input Impedance, Low Drift
- Single Supply, 5 to 36 Volts
- Linearity: ±0.05% FS
- Low Power: 1.2mA Quiescent Current
- Full Scale Frequency up to 100kHz
- 1.00 Volt Reference
- Thermometer Output (1mV/K)
- F-V Applications
- F-V Applications
- MIL-STD-883 Compliant Versions Available

PRODUCT DESCRIPTION

The AD537 is a monolithic V-F converter consisting of an input amplifier, a precision oscillator system, an accurate internal reference generator and a high current output stage. Only a single external RC network is required to set up any full scale (F.S.) frequency up to 100kHz and any F.S. input voltage up to ±30V. Linearity error is as low as ±0.05% for 10kHz F.S., and operation is guaranteed over an 80dB dynamic range. The overall temperature coefficient (excluding the effects of external components) is typically ±30ppm/°C. The AD537 operates from a single supply of 5 to 36V and consumes only 1.2mA quiescent current.

A temperature-proportional output, scaled to 1.00mV/K, enables the circuit to be used as a reliable temperature-to-frequency converter; in combination with the fixed reference output of 1.00V, offset scales such as 0°C or 0°F can be generated.

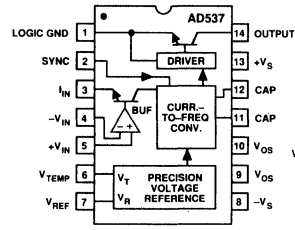
The low drift (1μV/°C typ) input amplifier allows operation directly from small signals (e.g., thermocouples or strain gages) while offering a high (250MΩ) input resistance. Unlike most V-F converters, the AD537 provides a square-wave output, and can drive up to 12 TTL loads, LEDs, very long cables, etc.

The excellent temperature characteristics and long-term stability of the AD537 are guaranteed by the primary band-gap reference generator and the low T.C. silicon chromium thin film resistors used throughout.

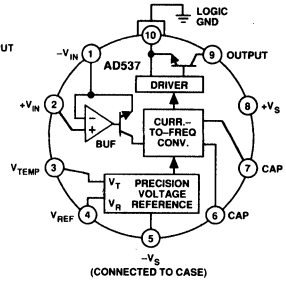
The device is available in either a TO-116 ceramic DIP or a TO-100 metal can; both are hermetically sealed packages.

PIN CONFIGURATIONS

"D" Package – TO-116



"H" Package – TO-100



The AD537 is available in three performance/temperature grades; the J and K grades are specified for operation over the 0 to +70°C range while the AD537S is specified for operation over the extended temperature range, -55°C to +125°C.

PRODUCT HIGHLIGHTS

1. The AD537 is a complete V-F converter requiring only an external RC timing network to set the desired full scale frequency and a selectable pull-up resistor for the open-collector output stage. Any full-scale input voltage range from 100mV to 10 volts (or greater, depending on $+V_S$) can be accommodated by proper selection of timing resistor. The full scale frequency is then set by the timing capacitor from the simple relationship, f = V/10RC.
2. The power supply requirements are minimal, only 1.2mA quiescent current is drawn from a single positive supply from 4.5 to 36 volts. In this mode, positive inputs can vary from 0 volts (ground) to ($+V_S$ - 4) volts. Negative inputs can easily be connected for below ground operation.
3. F-V converters with excellent characteristic are also easy to build by connecting the AD537 in a phase-locked loop. Application particulars are shown in Figure 6.
4. The versatile open-collector NPN output stage can sink up to 20mA with a saturation voltage less than 0.4 volts. The Logic Common terminal can be connected to any level between ground (or $-V_S$) and 4 volts below $+V_S$. This allows easy direct interface to any logic family with either positive or negative logic levels.
5. The AD537 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Product Databook or current AD537/883B data sheet for detailed specifications.

NOTES

*Specifications same as AD537JH.

**Specifications same as AD537K.

Specifications subject to change without notice.

[1] Nonlinearity is specified for a current input level (I_{IN}) to the converter from 0.1 to 1000μA. Converter has 100% overrange capability up to I_{IN} = 2000μA with slightly reduced linearity. Nonlinearity is defined as deviation from a straight line from zero to full scale, expressed as a percentage of full scale.

[2] Guaranteed not tested.

[3] Maximum voltage input level is equal to the supply on either input terminal. However, large negative voltage levels can be applied to the negative terminal if the input is scaled to a nominal 1mA full scale through an appropriate value resistor (see Figure 2).

[4] Loading the 1.0 volt or 1mV/K outputs can cause a significant change in overall circuit performance, as indicated in the applications section. To maintain normal operation, these outputs should be operated into the external buffer or an external amplifier.

[5] Temperature reference output performance is specified from 0 to +70°C for "J" and "K" devices, -55°C to +125°C for "S" model.

[6] D = Ceramic DIP; H = Hermetic Metal Can. For outline information see Package Information section.

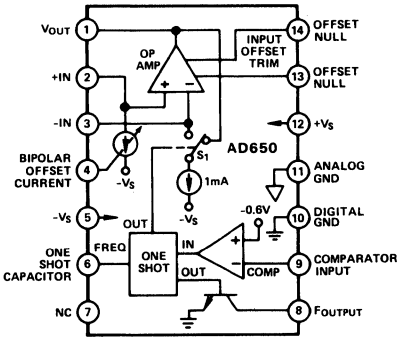
[7] For AD537/883B specifications, refer to Analog Devices Military Products Databook.

Voltage-to-Frequency and Frequency-to-Voltage Converter

AD650

FEATURES
V/F Conversion to 1MHz
Reliable Monolithic Construction
Very Low Nonlinearity
0.002% typ at 10kHz
0.005% typ at 100kHz
0.07% typ at 1MHz
Input Offset Trimmable to Zero
CMOS or TTL Compatible
Unipolar, Bipolar, or Differential V/F
V/F or F/V Conversion
Available in Surface Mount
MIL-STD-883-Compliant Versions Available

PIN CONFIGURATION



PRODUCT DESCRIPTION

The AD650 V/F/V (voltage-to-frequency or frequency-to-voltage converter) provides a combination of high frequency operation and low nonlinearity previously unavailable in monolithic form. The inherent monotonicity of the V/F transfer function makes the AD650 useful as a high-resolution analog-to-digital converter. A flexible input configuration allows a wide variety of input voltage and current formats to be used, and an open-collector output with separate digital ground allows simple interfacing to either standard logic families or opto-couplers.

The linearity error of the AD650 is typically 20ppm (0.002% of full scale) and 50ppm (0.005%) maximum at 10kHz full scale. This corresponds to approximately 14-bit linearity in an analog-to-digital converter circuit. Higher full-scale frequencies or longer count intervals can be used for higher resolution conversions. The AD650 has a useful dynamic range of six decades allowing extremely high resolution measurements. Even at 1MHz full scale, linearity is guaranteed less than 1000ppm (0.1%) on the AD650KN, KP, BD and SD grades.

In addition to analog-to-digital conversion, the AD650 can be used in isolated analog signal transmission applications, phased-locked-loop circuits, and precision stepper motor speed controllers. In the F/V mode, the AD650 can be used in precision tachometer and FM demodulator circuits.

The input signal range and full-scale output frequency are user-programmable with two external capacitors and one resistor. Input offset voltage can be trimmed to zero with an external potentiometer.

The AD650JN and AD650KN are offered in a plastic 14-pin DIP package. The AD650JP and AD650KP are available in a 20-pin plastic leaded chip carrier (PLCC). Both plastic packaged versions of the AD650 are specified for the commerical (0 to +70°C) temperature range. For industrial temperature range (−25°C to +85°C) applications, the AD650AD and AD650BD are offered in a ceramic package. The AD650SD is specified for the full −55°C to +125°C extended temperature range.

PRODUCT HIGHLIGHTS

1. In addition to very high linearity, the AD650 can operate at full scale output frequency up to 1MHz. The combination of these two features makes the AD650 an inexpensive solution for applications requiring high resolution monotonic A/D conversion.
2. The AD650 has a very versatile architecture that can be configured to accommodate bipolar, unipolar, or differential input voltages, or unipolar input currents.
3. TTL or CMOS compatibility is achieved using an open collector frequency output. The pullup resistor can be connected to voltages up to +30V, or +15V or +5V for conventional CMOS or TTL logic levels.
4. The same components used for V/F conversion can also be used for F/V conversion by adding a simple logic biasing network and reconfiguring the AD650.
5. The AD650 provides separate analog and digital grounds. This feature allows prevention of ground loops in real-world applications.
6. The AD650 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD650/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

CIRCUIT OPERATION

UNIPOLAR CONFIGURATION

The AD650 is a *charge balance* voltage-to-frequency converter. In the connection diagram shown in Figure 1, or the block diagram of Figure 2a, the input signal is converted into an equivalent current by the input resistance R_{IN}. This current is *exactly* balanced by an internal feedback current delivered in short, timed bursts from the switched 1mA internal current source. These bursts of current may be thought of as precisely defined packets of charge. The required number of charge packets, each producing one pulse of the output transistor, depends upon the amplitude of the input signal. Since the number of charge packets delivered per unit time is dependent on the input signal amplitude, a linear voltage-to-frequency transformation will be accomplished. The frequency output is furnished via an open collector transistor.

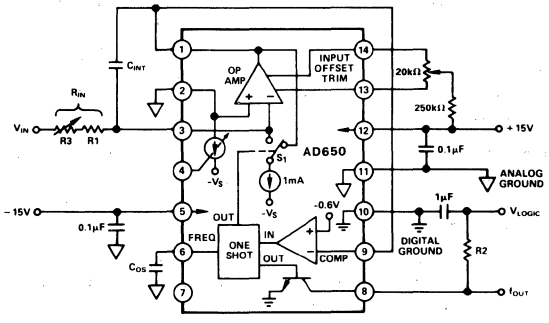

Figure 1. Connection Diagram for V/F Conversion, Positive Input Voltage

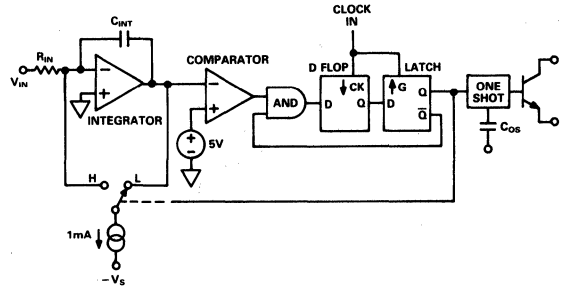
Monolithic Synchronous Voltage-to-Frequency Converter

AD652

FEATURES

- **Full-Scale Frequency (Up to 2MHz) Set by External System Clock**
- **Extremely Low Linearity Error (0.005% max at 1MHz FS, 0.02% max at 2MHz FS)**
- **No Critical External Components Required**
- **Accurate 5V Reference Voltage**
- **Low Drift (25ppm/°C max)**
- **Dual or Single Supply Operation**
- **Voltage or Current Input**
- **MIL-STD-883 Compliant Versions Available**

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD652 Synchronous Voltage-to-Frequency Converter (SVFC) is a powerful building block for precision analog-to-digital conversion, offering typical nonlinearity of 0.002% (0.005% maximum) at a 100kHz output frequency. The inherent monotonicity of the transfer function and wide range of clock frequencies allows the conversion time and resolution to be optimized for specific applications.

The AD652 uses a variation of the popular charge-balancing technique to perform the conversion function. The AD652 uses an external clock to define the full-scale output frequency, rather than relying on the stability of an external capacitor. The result is a more stable, more linear transfer function, with significant application benefits in both single- and multi-channel systems.

Gain drift is minimized using a precision low-drift reference and low-TC on-chip thin-film scaling resistors. Furthermore, the initial gain error is reduced to less than 0.5% by the use of laser-wafer-trimming.

The analog and digital sections of the AD652 have been designed to allow operation from a single-ended power source, simplifying its use with isolated power supplies.

The AD652 is available in five performance grades. The 20-pin PLCC packaged JP and KP grades are specified for operation over the 0 to +70°C commercial temperature range. The 16-pin cerdip-packaged AQ and BQ grades are specified for operation over the −40°C to +85°C industrial temperature range, and the AD652SQ is available for operation over the full −55°C to +125°C extended temperature range.

PRODUCT HIGHLIGHTS

1. The use of an external clock to set the full-scale frequency allows the AD652 to achieve linearity and stability far superior to other monolithic VFCs. By using the same clock to drive the AD652 and (through a suitable divider) also set the counting period, conversion accuracy is maintained independent of variations in clock frequency.
2. The AD652 Synchronous VFC requires only a single external component (a noncritical integrator capacitor) for operation.
3. The AD652 includes a buffered, accurate 5V reference which is available to the user.
4. The clock input of the AD652 is TTL and CMOS compatible and can also be driven by sources referred to the negative power supply. The flexible open-collector output stage provides sufficient current sinking capability for TTL and CMOS logic, as well as for optical couplers and pulse transformers. A capacitor-programmable one-shot is provided for selection of optimum output pulse width for power reduction.
5. The AD652 can also be configured for use as a synchronous F/V converter for isolated analog signal transmission.
6. The AD652 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD652/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

DEFINITIONS OF SPECIFICATIONS

GAIN ERROR – The gain of a voltage-to-frequency converter is that scale factor setting that provides the nominal conversion relationship, e.g. 1MHz full scale. The "gain error" is the difference in slope between the actual and ideal transfer functions for the V-F converter.

LINEARITY ERROR – The "linearity error" of a V-F is the deviation of the actual transfer function from a straight line passing through the endpoints of the transfer function.

GAIN TEMPERATURE COEFFICIENT – The gain temperature coefficient is the rate of change in full-scale frequency as a function of the temperature from +25°C to T_{min} or T_{max}.

THEORY OF OPERATION

A synchronous VFC is similar to other voltage-to-frequency converters in that an integrator is used to perform a charge-balance of the input signal with an internal reference current. However, rather than using a one-shot as the primary timing element which requires a high quality and low drift capacitor, a synchronous voltage-to-frequency converter (SVFC) uses an external clock; this allows the designer to determine the system stability and drift based upon the external clock selected. A crystal oscillator may also be used if desired.

The SVFC architecture provides other system advantages besides low drift. If the output frequency is measured by counting pulses gated to a signal which is derived from the clock, the clock stability is unimportant and the device simply performs as a voltage controlled frequency divider, producing a high resolution A/D. If a large number of inputs must be monitored simultaneously in a system, the controlled timing relationship between the frequency output pulses and the user supplied clock greatly simplifies this signal acquisition. Also, if the clock signal is provided by a VFC, then the output frequency of the SVFC will be proportional to the product of the two input voltages. Hence, multiplication and A-to-D conversion on two signals are performed simultaneously.

The pinouts of the AD652 SVFC are shown in Figure 1.

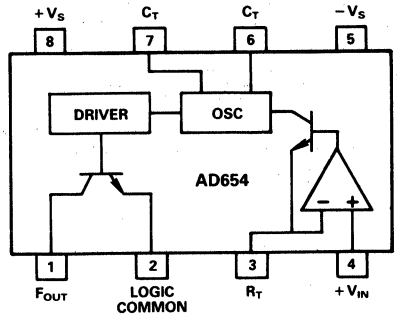
Low Cost Monolithic Voltage-to-Frequency Converter

AD654

FEATURES
Low Cost
Single or Dual Supply, 5 to 36 Volts, ±5V to ±18V
Full Scale Frequency Up to 500kHz
Minimum Number of External Components Needed
Versatile Input Amplifier
Positive or Negative Voltage Modes
Negative Current Mode
High Input Impedance, Low Drift
Low Power: 2.0mA Quiescent Current
Low Offset: 1mV

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD654 is a monolithic V/F converter consisting of an input amplifier, a precision oscillator system, and a high current output stage. A single RC network is all that is required to set up any full scale (F.S.) frequency up to 500kHz and any F.S. input voltage up to ±30V. Linearity error is only 0.03% for a 250kHz F.S., and operation is guaranteed over an 80dB dynamic range. The overall temperature coefficient (excluding the effects of external components) is typically ±50ppm/°C. The AD654 operates from a single supply of 5 to 36V and consumes only 2.0mA quiescent current.

The low drift (4μV/°C typ) input amplifier allows operation directly from small signals such as thermocouples or strain gauges while offering a high (250MΩ) input resistance. Unlike most V/F converters, the AD654 provides a square-wave output, and can drive up to 12 TTL loads, opto-couplers, long cables, or similar loads.

PRODUCT HIGHLIGHTS

1. Packaged in both an 8-pin mini-DIP and an 8-pin SOIC package, the AD654 is a complete V/F converter requiring only an RC timing network to set the desired full scale frequency and a selectable pull-up resistor for the open-collector output stage. Any full scale input voltage range from 100mV to 10 volts (or greater, depending on $+V_S$) can be accommodated by proper selection of the timing resistor. The full scale frequency is then set by the timing capacitor from the simple relationship, f = V/10RC.
2. A minimum number of low cost external components are necessary. A single RC network is all that is required to set up any full scale frequency up to 500kHz and any full scale input voltage up to ±30V.
3. Plastic packaging allows low cost implementation of the standard VFC applications: A/D conversion, isolated signal transmission, F/V conversion, phase-locked loops, and tuning switched-capacitor filters.
4. Power supply requirements are minimal; only 2.0mA of quiescent current is drawn from the single positive supply from 4.5 to 36 volts. In this mode, positive inputs can vary from 0 volts (ground) to $(+V_S - 4)$ volts. Negative inputs can easily be connected for below ground operation.
5. The versatile open-collector output stage can sink more than 10mA with a saturation voltage less than 0.4 volts. The Logic Common terminal can be connected to any level between ground (or $-V_S$) and 4 volts below $+V_S$. This allows easy direct interface to any logic family with either positive or negative logic levels.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]At f_{max} = 250kHz; R_T = 1kΩ, C_T = 390pF, I_{IN} = 0-1mA.
f_{max} = 500kHz; R_T = 1kΩ, C_T = 200pF, I_{IN} = 0-1mA.

[2]The sink current is the amount of current that can flow into Pin 1 of the AD654 while maintaining a maximum voltage of 0.4V between Pin 1 and Logic Common.

[3]N = Plastic DIP; R = SOIC. For outline information see Package Information section.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

Maximum Input Voltage
(Pins 3, 4) to $-V_S$ . . . . . $-300mV$ to $+V_S$
Maximum Output Current
Instantaneous 50mA
Sustained 25mA
Logic Common to $-V_S$ . . . . . $-500mV$ to $(+V_S - 4)$
Storage Temperature Range . . . . . $-65°C$ to $+150°C$

CIRCUIT OPERATION

The AD654's block diagram appears in Figure 1. A versatile operational amplifier serves as the input stage; its purpose is to convert and scale the input voltage signal to a drive current in the NPN follower. Optimum performance is achieved when, at the full scale input voltage, a 1mA drive current is delivered to the current-to-frequency converter (an astable multivibrator). The drive current provides both the bias levels and the charging current to the externally connected timing capacitor. This "adaptive" bias scheme allows the oscillator to provide low nonlinearity over the entire current input range of 100nA to 2mA. The square wave oscillator output goes to the output driver which provides a floating base drive to the NPN power transistor. This floating drive allows the logic interface to be referenced to a level other than $-V_S$.

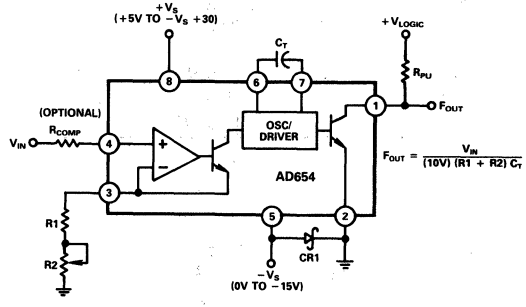

Figure 1. Standard V-F Connection for Positive Input Voltages

V/F CONNECTION FOR POSITIVE INPUT VOLTAGES

In the connection scheme of Figure 1, the input amplifier presents a very high (250MΩ) impedance to the input voltage, which is converted into the proper drive current by the scaling resistors at pin 3. Resistors R1 and R2 are selected to provide a 1mA full scale current with enough trim range to accommodate the AD654's 10% FS error and the components' tolerances. Full scale currents other than 1mA can be chosen, but linearity will be reduced; 2mA is the maximum allowable drive. The AD654's positive input voltage range spans from $-V_S$ (ground in single supply operation) to four volts below the positive supply. Power supply rejection degrades as the input exceeds $(+V_S - 3.75V)$ and at $(+V_S - 3.5V)$ the output frequency goes to zero.

As indicated by the scaling relationship in Figure 1, a 0.01μF timing capacitor will give a 10kHz full scale frequency, and 0.001μF will give 100kHz with a 1mA drive current. Good V/F linearity requires the use of a capacitor with low dielectric absorption (DA), while the most stable operation over temperature calls for a component having a small tempco. Polystyrene, polypropylene, or Teflon* capacitors are preferred for tempco and dielectric absorption; other types will degrade linearity. The capacitor should be wired very close to the AD654. In Figure 1, Schottky diode CR1 (MBD101) prevents logic common from dropping more than 500mV below $-V_S$. This diode is not required if $-V_S$ is equal to logic common.

V/F CONNECTIONS FOR NEGATIVE INPUT VOLTAGE OR CURRENT

The AD654 can accommodate a wide range of negative input voltages with proper selection of the scaling resistor, as indicated in Figure 2. This connection, unlike the buffered positive connection, is not high impedance because the signal source must supply the 1mA F.S. drive current. However, large negative voltages beyond the supply can be handled easily by modifying the scaling resistors appropriately. If the input is a true current source, R1 and R2 are not used. Again, diode CR1 prevents latch-up by insuring Logic Common does not drop more than 500mV below $-V_S$. The clamp diode (MBD101) protects the AD654 input from "below $-V_S$" inputs.

Intelligent Digitizing Signal Conditioner

AD1B60

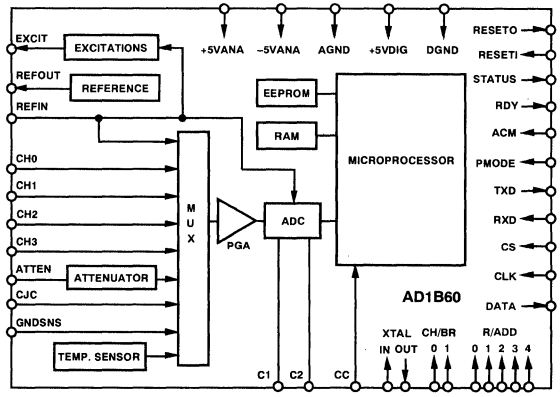
FEATURES

- Complete Sensor-to-Digital Signal Conditioning and Data Conversion
- Multiple Input Ranges
  Thermocouples: J, K, T, E, R, S, and B
  RTDs: 100 Ω Platinum (α = 385 and 392)
  Voltage: Ten Ranges from ±10 mV to ±10 V
  Two Custom Ranges (User Defined)
- High Resolution: ±0.15°C (Typical, Temperature Input) or ±0.0015% (Typical, Voltage Input)
- High Accuracy: ±0.2°C (Typical, RTD Input) or ±0.005% (Typical, Voltage Input)
- Cold Junction Compensation for Thermocouples
- Open Thermocouple Detection
- RTD Excitation
- Lead Resistance Compensation for RTDs
- Autozeroing, Data Scaling, and Linearization
- Data Output in Engineering Units
- 2-Wire Asynchronous Communication I/O Port
- High Speed Synchronous Data Output Port
- Eight Integration Times: 2 ms to 200 ms
- Internal EEPROM Stores Calibration and Configuration Parameters

APPLICATIONS

Industrial Temperature Measurement Systems
Process Control Systems
Multichannel Thermocouple/RTD Systems
Analytical Instruments

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD1B60 is an intelligent, microcontroller-based device that performs signal conditioning, excitation, compensation, linearization, and analog-to-digital conversion for a variety of low bandwidth industrial and analytical signals. Due to its highly integrated, mixed-signal design, the AD1B60 is small and inexpensive, offering designers increased flexibility and performance.

The AD1B60 is suited primarily for use with thermocouples and resistance temperature detectors (RTDs), but also accepts a broad range of low and high level voltage inputs. The AD1B60 converts sensor inputs to compensated, linearized, scaled, and autozeroed outputs represented in engineering units: degrees Celsius or volts.

Four modes of cold junction compensation (CJC) are supported for thermocouple applications. The AD1B60 also provides lead resistance compensation for 3-wire or 4-wire RTD connections.

Data is transmitted serially to simplify use of external optical and/or magnetic isolation devices. The AD1B60 has a bidirectional asynchronous communications port for control and for data output. Data is also available via a high-speed synchronous data output port.

Configuration parameters such as the input range and integration time of the AD1B60 can be programmed, both prior to installation and in the application. The AD1B60 incorporates EEPROM to store default and user-specified configuration and calibration values. No battery backups, potentiometers, or user-developed calibration software routines are required and no recalibration is necessary when the input range is changed.

AD1B60—SPECIFICATIONS

NOTES

[1]Accuracy specifications include factory calibration errors but do not include reference noise. Also, accuracy specifications for thermocouple ranges do not include CJC calculation errors, which depend on the calculation method chosen. To calculate total measurement error, add reference noise expressed as a percentage of the reference voltage to the specified accuracy error. Because reference noise results in a gain error, its effect is a percentage of reading. For example, a measurement made using the ±1 V input range and a reference with ±0.01% maximum noise would have a maximum error of ±0.007% FSR ± 0.01% of reading. FSR = Full-Scale Range, i.e., span of input values. For thermocouple ranges, also add to the measurement error the values in Table A corresponding to the selected CJC type. For example, a measurement made with a Type J thermocouple, downloaded CJC temperature, and a reference with ±0.01% maximum noise would have a maximum error of ±0.456 °C ± 0.01 % of reading.

[2]At integration time ≥ 33.3 ms and equal to an integral number of power-line cycles.

[3]Temperature ranges use the International Practical Temperature Scale of 1968 (IPTS-68). Thermocouple accuracy specifies conformance to NIST Monograph 125. RTD accuracy specifies conformance to JIS C 1604, DIN 43760, and IEC 751.

[4]Errors expressed as ppm (parts per million) of reading.

[5]Excluding reference noise and drift.

[6]RTD measurement drift is digitally compensated to 25 ppm/°C of reading (maximum), including effects of reference, excitation current, and gain drift.

[7]RTD measurement accuracy is digitally compensated to values shown on first page of specification table.

[8]CJC excitation current is enabled only when the "Thermistor" CJC mode is selected; see Table V.

[9]Minimum throughput occurs at T_{INT} = 200 ms for any range selection. Maximum throughput occurs at T_{INT} = 2 ms for voltage ranges (ranges 0 through 9) only; see Table IV.

[10]User-supplied.

[11]Specified performance obtained with frequency of 11.0592 MHz ± 0.1%.

[12]−0.2 V < (+5VANA − +5VDIG) < 0.5 V for specified performance.

[13]Typical values are not tested or guaranteed. Operation which is specified without explicit reference to variation in operating conditions may differ as these conditions are altered.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Absolute Maximum Ratings apply individually only, not in combination.

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD1B60BS	−40°C to +85°C	S-64
AD1B60BJ	−40°C to +85°C	J-44
AD1B60/EB	−40°C to +85°C	Printed Circuit Board

NOTES

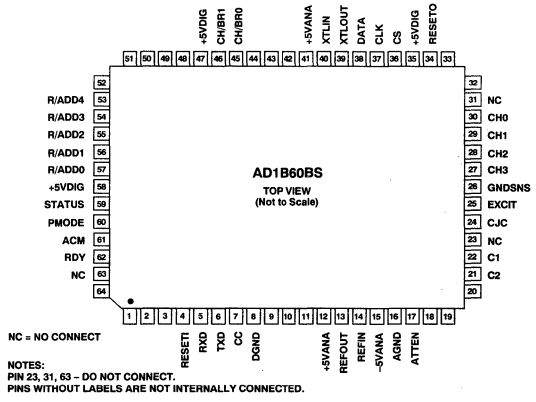
*S = Plastic Quad Flat Pack (PQFP), J = J-leaded Ceramic Chip Carrier, /EB = Evaluation Board with AD1B60BJ & Software. Consult factory for availability. For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD1B60 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

Table I. Pin Functions

BS #	BJ #	Name	Connection
4	18	RESETI	Reset input; active high. Initializes the AD1B60 to the pin-strapped and EEPROM default values. Connect to RESETO.
5	19	RXD	Receive data input for asynchronous port.
6	20	TXD	Transmit data output for asynchronous port.
7	21	CC	Continuous Conversion input. Enables synchronous signal integration or continuous conversion. While low, the AD1B60 waits in "idle mode." When CC goes high, the AD1B60 starts converting. While held high, the AD1B60 continuously converts input data.
8	22	DGND	Digital ground.
12	23	+5VANA	+5 V, ± 5% analog power supply.
13	24	REFOUT	Output from internal reference (+2.5 V).
14	25	REFIN	Reference input; may be connected directly to REFOUT.
15	26	−5VANA	−5 V, ± 5% analog power supply.
16	27	AGND	Analog ground.
17	28	ATTEN	5:1 attenuator input for ±5 V and ±10 V input voltages.
21	29	C2	External integration capacitor (nominally 2.2 nF).
22	30	C1	External integration capacitor.
23	31	NC	Make no connection (factory test).
24	32	CJC	External CJC sensor input. Also outputs 20 μA excitation current in thermistor CJC mode.
25	33	EXCIT	Excitation Output: provides 10 nA for open thermocouple detection if a thermocouple range is selected, or 200 μA excitation if an RTD range is selected.
26	34	GNDSNS	Sense input for ground potential. Connect to AGND (typical).
27	35	CH3	Channel 3 signal input.
28	36	CH2	Channel 2 signal input.
29	37	CH1	Channel 1 signal input.
30	38	CH0	Channel 0 signal input.
31	39	NC	Make no connection (factory test).
34	40	RESETO	Output from the power-on reset/brownout detect/watchdog timer circuit; active high. Connect to RESETI.
35	41	+5VDIG	+5 V, ± 5% digital power supply; connect also to other +5 VDIG pins.
36	42	CS	Chip select input (low to select). Connect to DGND if not used.
37	43	CLK	Synchronous serial shift clock input. Connect to DGND if not used.
38	44	DATA	Synchronous serial data output.
39	1	XTLOUT	External crystal (11.0592 MHz).
40	2	XTL1N	External crystal (11.0592 MHz) or external logic-level clock input.
41	3	+5VANA	+5 V, ± 5% analog power supply.
45, 46	4, 5	CH/BR0-1	Channel select inputs when PMODE is low at reset. Baud rate select inputs when PMODE is high at reset.
47	6	+5VDIG	+5 V, ± 5% digital power supply; connect also to other +5 VDIG pins.
53–57	7–11	R/ADD4-0	Range select inputs if PMODE is low at reset. Address select inputs if PMODE and ACM are high at reset. External pull-ups are required.
58	12	+5VDIG	+5 V, ± 5% digital power supply; connect also to other +5 VDIG pins.
59	13	STATUS	Computation status output. If Status is high, results from the previous signal integration are being computed; if STATUS is low, results are available.
60	14	PMODE	Mode select input for CH/BR and R/ADDR pins; high or low state sensed at power-up and reset. Specifies whether input range, input channel, device address, and baud rate are determined by external pins or by values in EEPROM.
61	15	ACM	Addressed Communication Mode input. When ACM is high, address and CRC are enabled.
62	16	RDY	Ready (integration status) output. If RDY is high, the AD1B60 is integrating the signal; if RDY is low, the AD1B60 is integrating a background input.
63	17	NC	Make no connection (factory test).



AD1B60 Pin Assignments

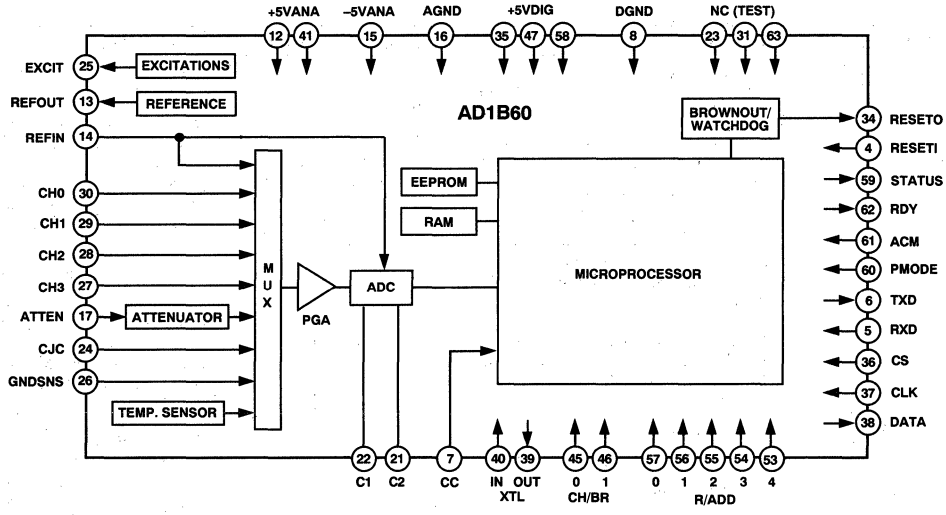


Figure 1. Functional Block Diagram

FUNCTIONAL DESCRIPTION

The AD1B60 is a complete data acquisition subsystem in a single package which interfaces directly to a sensor and a host processor (see Figure 1). The sensor is applied to one or more of the multiplexer inputs and amplified by the programmable gain amplifier. Excitation currents for RTDs, open thermocouple input detection, and cold junction compensation sensors are provided.

The AD1B60 has an input multiplexer with four channels for low level input signals and one channel with an attenuator for high level inputs. There are also reference and zero inputs, a cold junction compensation channel, and an internal temperature sense channel on the multiplexer. Voltage input ranges are ±10 mV full scale to ±10 V full scale.

The multiplexer feeds a programmable gain amplifier (PGA), which has a gain range of 1 to 128. The output of the PGA is applied to an integrating voltage-to-frequency converter, which is resolved by the microprocessor. The microprocessor controls the input multiplexer and PGA alternately selecting an input channel, voltage reference, ground, or other signal channel necessary for an accurate measurement.

For a voltage measurement, the AD1B60 will measure the input voltage, measurement ground and reference voltage, and will calculate the value of the input voltage ratiometrically to the reference and then generate an output value in volts.

For thermocouple measurements, the AD1B60 will also read a cold junction sensor, calculate the required CJC correction voltage, apply it to the voltage reading of the thermocouple, and generate an output in degrees Celsius.

For RTD measurements, the AD1B60 will perform 3- or 4-wire lead resistance compensation, compensate for internal excitation and gain drifts and generate an output in degrees Celsius.

The AD1B60's standard input ranges include the seven NIST thermocouple standards, two platinum RTD ranges, and ten voltage ranges.

In addition, the AD1B60 can use two ranges stored in internal EEPROM. These "custom" ranges are easily created by the user through use of the AD1B60 Custom Range Generation Software included with every Evaluation Board. Several example files, such as a Type N thermocouple range, are also included with the software.

With each conversion, the AD1B60 reports status information, input channel, and an overflow flag. The AD1B60 communicates via one or both of its serial ports: a 2-wire asynchronous I/O port up to 19.2 kbaud, and a 3-wire synchronous data output port up to 5 Mbps.

The AD1B60 contains a brownout detector and watchdog monitor circuit. If any of the power supplies falls below a threshold, or if the internal microprocessor fails to trigger the watchdog timer, this circuit will generate a reset output.

CONFIGURABLE PARAMETERS

You can set the following parameters of the AD1B60:

- Device Address
- Baud Rate
- Channel Selection
- Input Range
- Integration Time
- Cold Junction Compensation Mode
- RTD Connection Mode

Depending on the parameter, you can change values in the following ways:

- Execute AD1B60 commands to change values in EEPROM.
- Set specified pins on the AD1B60.
- Execute AD1B60 commands to change values in RAM.

The factory-programmed default values of the configurable parameters are listed in Table II.

If the default values for the device address and baud rate do not match those in your application, you must reset the AD1B60 with the PMODE pin high and the desired device address and baud rate set by AD1B60 pins. Using AD1B60 commands, you can change the EEPROM-based defaults, and then power up the AD1B60 with PMODE low to use the new default values from EEPROM.

The following section describes the configurable parameters. The COMMAND SET section describes the commands used to change parameter settings.

Table II. Configurable Parameters and their Default Values

Configurable Parameter	Factory Default Value	For Details, See
Device Address	0	Table I
Baud Rate	9600	Table VII
Channel Selection	0	Figure 5
Input Range	Type J Thermocouple	Table III
Integration Time	100 ms	Table IV
Cold Junction Compensation Mode	Direct Connection of a Thermistor	Table V
RTD Connection Mode	3-Wire	Figure 6

CONFIGURATION PARAMETER DESCRIPTIONS

Device Address

In Addressed Communication Mode (ACM pin high), you can connect a cluster of up to 32 AD1B60s to a single communication port. Each AD1B60 in a cluster must have a unique address from 0 to 31 (0 to 1F hex).

When the AD1B60 is reset with PMODE high, the address is read from R/ADD 4–0 pins. Refer to Table I for more information on using the pins of the AD1B60.

When the AD1B60 is reset with PMODE low, the address is read from EEPROM. You can change the default address stored in EEPROM by executing the WR_EPM_PARS command.

Baud Rate

You can set one of the following baud rates for the AD1B60: 2400, 4800, 9600 (the factory default), or 19200.

When the AD1B60 is reset with PMODE low, the baud rate is read from EEPROM. You can change the default baud rate stored in EEPROM by executing the WR_EPM_PARS command.

When the AD1B60 is reset with PMODE high, the baud rate is read from the CH/BR 0–1 pins.

Channel Selection

Although the AD1B60 is optimized for single-channel applications, you can use up to five input channels on one device. The AD1B60 checks the input channel selection before each conversion. Note that selecting an RTD or high voltage input range also determines the channel(s).

If the AD1B60 is powered up with PMODE high, Channel 0 is selected. For thermocouple and low level voltage ranges, you can select an input channel using the SEL_CH command. Check the channel address in the ADSTAT byte returned with the data to ensure that the data represents the correct channel. Also check ADSTAT's Valid Data flag after changing channels. You may have to wait up to two integration times for valid data when changing channels on the same input range. Refer to the COMMAND SET section for more information on SEL_CH.

If the AD1B60 is reset with PMODE low, the input channel is determined by the CH/BR 0–1 pins.

Input Ranges

The AD1B60 supports the input ranges listed in Table III.

If the standard input ranges (numbered 00 through 12 hex) do not meet the requirements of your application, you can download up to two additional user defined custom input ranges into the AD1B60. Custom ranges are generated by the user with the Custom Range Generation Software. Refer to the following subsection for more information on downloading input ranges.

The input range is determined by the R/ADD 4–0 pins when the AD1B60 is reset with PMODE low.

Table III. Input Ranges

Input Range	Range Code (In Hex)
±10 mV	00
±20 mV	01
±50 mV	02
±100 mV	03
±200 mV	04
±500 mV	05
±1 V	06
±2 V	07
±5 V (ATTEN Input)	08
±10 V (ATTEN Input)	09
Type J Thermocouple, 0°C to 760°C*	0A*
Type K Thermocouple, 0°C to 1000°C	0B
Type T Thermocouple, −100°C to +400°C	0C
Type E Thermocouple, 0°C to 1000°C	0D
Type R Thermocouple, 500°C to 1750°C	0E
Type S Thermocouple, 500°C to 1750°C	0F
Type B Thermocouple, 500°C to 1800°C	10
Platinum RTD, 100 Ω, α = 0.00385, −200°C to +800°C	11
Platinum RTD, 100 Ω, α = 0.00392, −200°C to +800°C	12
Not Used	13 to 1D
User Range 1	1E
User Range 2	1F

NOTE
*Default Configuration

The input range is read from EEPROM when the AD1B60 is reset with PMODE high. To change the input range stored in EEPROM, execute the WR_EPM_PARS command. You can also change the input range by using the WR_RAM_PARS command. This command changes the range immediately and does not affect values in EEPROM. You can issue the RD_RAM_PARS command to read the current configuration.

You can use only one input range at a time. When you change the input range, you may have to wait up to 13 integration times to ensure that the output data is valid, as indicated by the Valid Data flag in the ADSTAT byte. Therefore, you should only change the input range in applications having very low bandwidth.

Downloading User Input Ranges
You can choose up to two additional user defined input ranges to download into the AD1B60's EEPROM at any time. A range is typically generated by a user in order to accept a sensor or input signal not supported by the standard AD1B60 internal ranges or to provide a range that optimizes the output data for easier calculations or other considerations.

Ranges can be simply made by using the IBM PC compatible, Windows version "AD1B60 Custom Range Generation Software." All AD1B60 software is included free of charge with each Evaluation Board.

To download an input range to EEPROM, execute the LOAD_RNG command. You must execute LOAD_RNG eight times to download the entire input range to EEPROM. Refer to the COMMAND SET section for more information on this command.

Reading User-Downloaded Input Ranges
To verify a user-downloaded input range, execute the GET_RNG command. You must execute GET_RNG eight times to read the entire input range from EEPROM.

Integration Time
You can set the integration time used by the AD1B60's A/D converter. The integration time and the input range affect the overall conversion rate. Table IV shows available integration times and the range of corresponding conversion rates, as well as line frequencies that have high normal mode rejection (NMR). Voltage ranges have the fastest conversion rates. Because of the extensive calculation required for linearization and compensation, the conversion rate for Type K thermocouples is the slowest of the AD1B60's standard ranges.

Setting the integration time equal in duration to an integral number of power line cycles will cause high normal mode rejection at the line frequency. The fastest available integration times for 50 Hz and 60 Hz are 40 ms and 33.3 ms, respectively; each time is equal to two power line cycles. The default integration time, 100 ms, is an integral multiple of both power line periods.

You can change the default integration time stored in EEPROM by executing the WR_EPM_PARS command. You can change the integration time without changing values in EEPROM by executing the WR_RAM_PARS command. You can use the RD_RAM-_PARS command to read back the current configuration.

Cold Junction Compensation Mode
The AD1B60 provides four different CJC modes for thermocouple ranges, described in Table V.

You can change the default CJC mode stored in EEPROM by executing the WR_EPM_PARS command.

You can change the CJC mode without changing the EEPROM default by executing the WR_RAM_PARS command. To read the current CJC mode from RAM, execute the RD_RAM_PARS command. To read the current value of the CJC temperature from RAM, execute the RD_CJC command.

RTD Connection Mode
The AD1B60 supports 3-wire and 4-wire RTD connection modes (see Figures 10, 11, and 12); 3-wire is the default configuration.

You can change the default RTD connection mode stored in EEPROM by executing the WR_EPM_PARS command.

You can change the RTD connection mode without changing the EEPROM default by executing the WR_RAM_PARS command. To read back the current configuration stored in RAM, execute the RD_RAM_PARS command.

Table IV. Integration Times

Integration Time	Conversion Rate	High NMR Frequency	AUX Byte Bits B2–B0
200 ms	2.5 per second	50 or 60 Hz	000
100*	5*	50 or 60	001*
60	8.3	50	010
50	9.9	60	011
40	12.3	50	100
33.3	14.8	60	101
5	44† to 87.5‡		110
2	48† to 100‡		111

NOTES
*Default Configuration
†Type K thermocouple with thermistor CJC (mode 00)
‡Voltage range with CJC disabled (Mode 11)

Table V. Cold Junction Compensation Modes

CJC Sensor Type	CJC Mode Description	CJC Excitation Current	Cold Junction Temperature Range	AUX Byte Code, Bits B6–B5
Thermistor*	Direct connection of a 10K3A1 thermistor made by Betatherm (Shrewsbury, Massachusetts, and Galway, Ireland). At +25°C, this thermistor's R = 10 kΩ, alpha = −4.4%/°C, and beta = 3892.	Enabled	−25°C to +70°C	00*
1 mV/K	A 1 mV/K external sensor is connected at the input. This mode allows the use of silicon sensors, such as the Analog Devices AD592 with a 1 kΩ resistor (see Figure 9).	Disabled	−25°C to +85°C	01
Downloaded	A user-defined value of an externally derived cold junction temperature is downloaded over the asynchronous communication port using the WR CJC command.	Disabled	-25°C to +85°C	10
CJC Calculation Disabled	No CJC calculations are performed by the AD1B60. An analog CJC, such as the Analog Devices AC1226, is connected at the input. This type of sensor must be externally configured for the specific thermocouple type.	Disabled	User-defined; must be in −25°C to +85°C range	11

NOTE
*Default Configuration

CONVERSION TIMING AND CONTROL

In normal operation, the Continuous Conversion (CC) Pin is high, and the AD1B60 performs continuous conversions, alternating between signal conversions and background conversions, such as autozero or cold junction compensation (see Figure 2a).

The RDY pin and the Ready flag in the ADSTAT byte are high while the AD1B60 integrates the input signal. The STATUS pin and Status flag in the ADSTAT byte are high while the AD1B60 computes the result of the signal integration. When STATUS goes low, the data is available at the Asynchronous Communication Port. When RDY goes high again for the next signal integration, the data from the prior conversion is available at the Synchronous Data Output Port.

When CC is low, signal conversions are suspended. After CC goes high, a signal conversion will start. This allows synchronizing the conversions to external events, or synchronizing multiple AD1B60s (see Figure 2b). If you communicate with the AD1B60 using the Asynchronous Communications Port, the time spent in communications service may increase the latency between the trigger and the signal conversion.

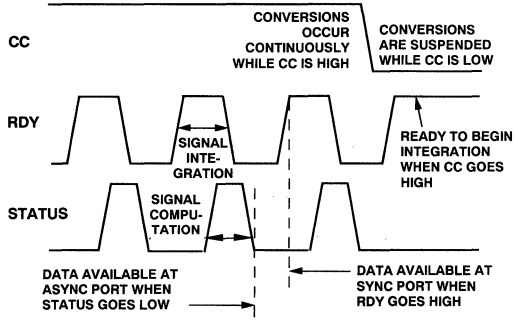

Figure 2a. Continuous Conversion

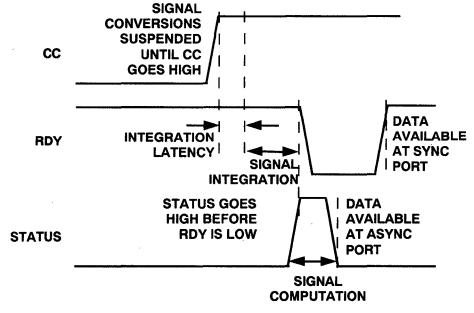

Figure 2b. Synchronizing Conversion

SERIAL COMMUNICATION PORTS

Asynchronous Communication Port

The asynchronous communication port is a two-wire, half-duplex, input/output port. You can connect the asynchronous port to host systems either at +5 V logic levels or by using external level translation to communication standards such as RS-232 and RS-422. The AD1B60 responds to the commands listed in the COMMAND SET section.

The asynchronous port operates at 2400, 4800, 9600, or 19200 baud using eight data bits, no parity, and one stop bit. Bytes are transmitted least significant bit first.

In Addressed Communications Mode (ACM), the asynchronous port supports device addressing and CRC error checking. Device addressing enables clusters of up to 32 AD1B60s to share a single communication line (see Figure 3). Cyclic Redundancy Codes (CRC) improve communication reliability in noisy environments. The AD1B60 uses CRC-16 ($x^{16} + x^{15} + x^2 + 1$) as a generator polynomial.

ACM is active when the ACM pin is high. When ACM is active, the address and CRC are required to accompany commands to the AD1B60, which will include address and CRC in its response. See the COMMAND PARAMETERS section for details on the format of address and CRC. The address and baud rate are read from either EEPROM or external pins at reset, depending on the state of the PMODE pin.

When the PMODE pin is low at reset, device address and async port baud rate are read from EEPROM, and input range and channel are read from R/ADD and CH/BR pins at reset. When PMODE is high at reset, address and baud rate are read from these pins, input range is read from EEPROM, and input channel is set to 0.

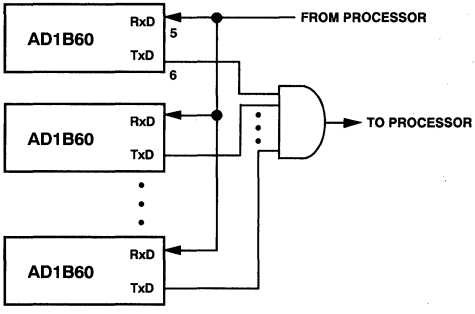

Figure 3. Connecting a Cluster of AD1B60s to a Communication Port

If you intend to use the AD1B60 with a device address or baud rate different from the values in EEPROM, reset the device with PMODE high and the desired address and baud rate selected through the R/ADD and CH/BR pins. You may then load the desired values of device address and baud rate into EEPROM to free these pins for selecting input range and channel.

If a message with an invalid address, command code, or CRC is received by an AD1B60, it will not respond to that message. The host may use a time-out to detect an AD1B60 that does not respond. If the host detects an error from an AD1B60, whether by invalid response or lack of response, it may issue a Break and retry the command.

The AD1B60 will detect Breaks to allow recovery from communications errors. The AD1B60 recognizes a Break when it receives a character with a zero (space) where the stop bit should be. The AD1B60 then resets its communications processes, and is ready to receive the next command. All AD1B60s on a line will recognize a Break.

Asynchronous communications with the AD1B60 are half-duplex. If a character is sent to an AD1B60 while it is transmitting, it ignores the character and continues transmitting. After its transmission is complete, the AD1B60 is ready to receive the next character.

Synchronous Data Output Port

The synchronous port is a 3-wire data output port. It is independent of the asynchronous port, and both can be accessed simultaneously, if desired.

Using the CS (chip select), CLK (clock input), and DATA (data output) pins of the AD1B60, you can read data at speeds up to 5 Mbps (see Figure 4). When RDY goes high at the beginning of a conversion cycle, the MSB of the previous data word appears at the DATA output (see Figures 2a and 2b). Bringing CS low freezes the data in the synchronous port buffer. Results of other conversions won't be transferred to the synchronous port buffer while CS is low. 15 CLK pulses will read out the remaining bits of the word in the synchronous port buffer. Further CLK pulses will continue to read out the same data bits from this circular buffer.

After all 16 bits are read, CS must be brought high and then low again to read the next word. CS must stay high for a minimum of 400 µs to allow the data buffer to be updated.

The synchronous port sends integer data only, in 16-bit twos complement or offset binary format, depending on the input range (see Table VI).

If you don't use the synchronous output port, ground the CS and CLK pins to minimize digital noise.

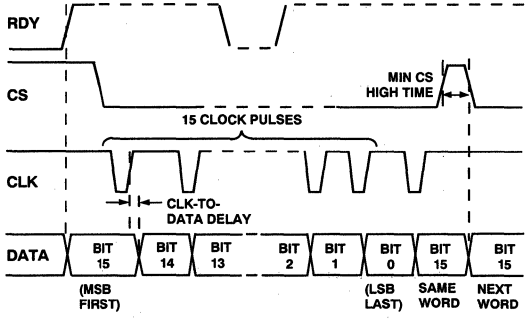

Figure 4. Reading Data from the Synchronous Port

Table VI. Integer Data Output Formats

Voltage Ranges (Twos Complement, in Hex)		Temperature Ranges (Offset Binary, in Hex)	
+Full Scale	7FFF	Top of Span	FFFF
Zero	0000		
Zero –1 LSB	FFFF		
–Full Scale	8000	Bottom of Span	0000

COMMAND PARAMETERS

This section describes the parameters of the AD1B60 commands, which are described in the next section. All values in <angle brackets> and [square brackets] are 8-bit bytes; values in [square brackets] are used only when ACM is active. Numbers followed by H are expressed in hexadecimal (hex) notation.

[Addr] represents the address of the AD1B60. It is required in the command and generated in the response only if ACM is active. Values for [addr] range from 00H to 1FH (0 to 31 decimal). The factory default value is 00H.

<ADSTAT>, shown in Figure 5, represents the status of the AD1B60. Values of ADSTAT range from 00H to FFH. ADSTAT's Valid Data flag and Input Channel should be checked on every measurement reading.

<Aux>, shown in Figure 6, represents the RTD connection mode, CJC mode, and integration time of the AD1B60. Values of <aux> range from 00H to FFH and may be read via the RD_RAM_PARS command.

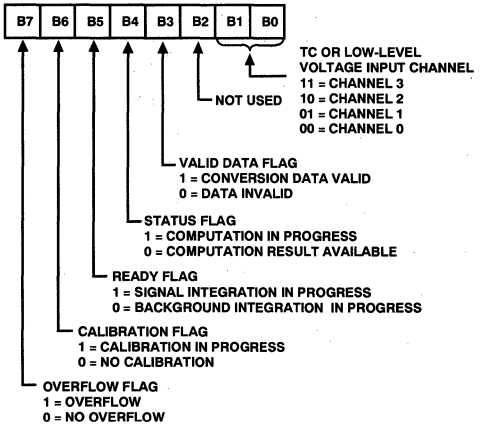

Figure 5. The ADSTAT Byte

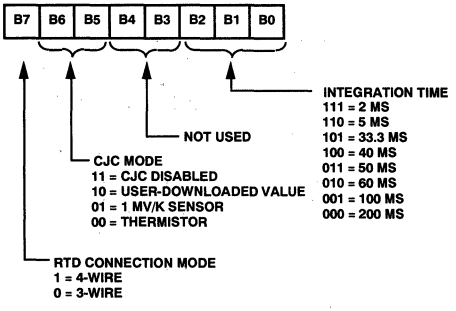

Figure 6. The Aux Byte

Table VII. Baud Rate Codes

Baud Rate	Baud Code (in Hex)
2400	00
4800	01
9600*	02*
19200	03

NOTE
*Default Configuration

<Baud> represents the baud rate code of the AD1B60. Table VII lists the codes associated the available baud rates.

<C0> through <C3> are four bytes that represent the CJC temperature, in ANSI/IEEE 754-single-precision floating-point format, and in degrees C. Values ranges from −25°C to +85°C. For example, in this format, a 25°C is expressed as 41 C8 00 00 (hexadecimal). <C0> contains the least significant byte of the mantissa, or 00H in this example; <C3> contains the sign bit and the 7 most significant bits of the exponent, or 41H in this example.

[CRC1] and [CRC2] represent the CRC-16 error checking value. These arguments are required in the command and generated in the response only if ACM is active. [CRC1] is the LSB; [CRC2] is the MSB.

<Device_addr> represents the new default address for the AD1B60. Values for <device_addr> range from 00H to 1FH (0 to 31 decimal).

<D0> through <D7> comprise an 8-byte segment of the user-selected input range in EEPROM. <D0> is the low order byte; <D7> is the high order byte.

<F0> through <F3> are four bytes that represent the floating-point data, in IEEE 754 standard format. See the description of <C0> through <C3>, above, for information on this format.

<INT_LO> and <INT_HI> represent the lower and upper eight bits, respectively, of the 16-bit integer representation of the data. Values range from 00H to FFH; see Table VI for data formats.

<Range> represents the input range code. Refer to Table III for a list of the available input range codes. The current range may be read via the RD_RAM_PARS command.

<Range_addr> represents the address of the 8-byte segment of the 64-byte input range in EEPROM. Range addresses 00H to 07H correspond to the eight, 8-byte segments of User Range 1 (code 1EH); range addresses 08H to 0FH correspond to the eight, 8-byte segments of User Range 2 (code 1FH).

COMMAND SET

The AD1B60 commands allow you to configure the AD1B60, read converted data and status information, and calibrate input ranges over the asynchronous port. This section describes the commands in detail.

Configuration Commands

The AD1B60 Command Set provides the configuration commands listed below. Note that the data written into RAM by WR_RAM_PARS, WR_CJC, and SEL_CH will be cleared at power-up and reset.

- **RD_RAM_PARS**

Reads back the current value of the configuration parameters from RAM.

Command Syntax
[addr] <02H> [CRC1] [CRC2]

Response Syntax
[addr] <02H> <range> <aux> [CRC1] [CRC2]

- **WR_RAM_PARS**

Writes new values of the configuration parameters in RAM. These values take effect immediately and do not change the default values in EEPROM.

Command Syntax
[addr] <04H> <range> <aux> [CRC1] [CRC2]

Response Syntax
[addr] <04H> [CRC1] [CRC2]

- **WR_EPM_PARS**

Writes new values of the configuration parameters in EEPROM. The new values do not change currently selected values in RAM and only take effect when the AD1B60 is powered up or reset.

Command Syntax
[addr] <05H> <range> <aux> <device-addr> <baud> [CRC1] [CRC2]

Response Syntax
[addr] <05H> [CRC1] [CRC2]

- **GET_RNG**

Reads an 8-byte segment of a downloadable input range from EEPROM. See LOAD_RNG, below.

Command Syntax
[addr] <07H> <range-addr> [CRC1] [CRC2]

Response Syntax
[addr] <07H> <D0> <D1> <D2> <D3> <D4> <D5> <D6> <D7> [CRC1] [CRC2]

- **LOAD_RNG**

Writes an 8-byte segment of a downloadable input range into EEPROM. LOAD_RNG and GET_RNG must be executed 8 times to write or read an entire 64-byte range. Each successive time, <range-addr> must increment by 1 to address the next segment.

Command Syntax
[addr] <08H> <range-addr> <D0> <D1> <D2> <D3> <D4> <D5> <D6> <D7> [CRC1] [CRC2]

Response Syntax
[addr] <08H> [CRC1] [CRC2]

- **RD_CJC**

Reads the current value of the CJC temperature in RAM, in °C. This value may have been measured by a thermistor or mV/K sensor, or loaded via a WR_CJC command.

Command Syntax
[addr] <03H> [CRC1] [CRC2]

Response Syntax
[addr] <03H> <C0> <C1> <C2> <C3> [CRC1] [CRC2]

- **WR_CJC**

Downloads to RAM a CJC temperature in °C, obtained from an external source. Only used in Downloaded CJC mode (mode 10).

Command Syntax
[addr] <06H> <C0> <C1> <C2> <C3> [CRC1] [CRC2]

Response Syntax
[addr] <06H> [CRC1] [CRC2]

- **SEL_CH**

Selects an input channel on the AD1B60 and stores the channel address in RAM. This command is not meaningful if the PMODE pin is low, or if the input range is RTD or attenuator; for these ranges, the channel is selected automatically.

Command Syntax
[addr] <0AH> <chan> [CRC1] [CRC2]

Response Syntax
[addr] <0AH> <chan> [CRC1] [CRC2]

Read Data Commands

The AD1B60 Command Set includes the following read data commands:

- **RD_INTDATA**

Reads converted data, in 16-bit integer format (see Table VI), and the conversion status.

Command Syntax
[addr] <00H> [CRC1] [CRC2]

Response Syntax
[addr] <00H> <INT_LO> <INT_HI> <ADSTAT> [CRC1] [CRC2]

- **RD_FPDATA**

Reads converted data, in IEEE 754 floating point format and engineering units, and the conversion status.

Command Syntax
[addr] <01H> [CRC1] [CRC2]

Response Syntax

CALIBRATION

The AD1B60 is calibrated with its internal reference at the factory prior to shipment. You can also calibrate the AD1B60 in your application, if desired. You should calibrate the AD1B60 if you use an external reference.

Calibrating the AD1B60 requires a precision reference excitation source for different input ranges. The accuracy of the AD1B60 depends on the accuracy of the calibration source. For best performance, calibrate the AD1B60 using the maximum integration time of 200 ms.

Note that calibrating certain input ranges, such as thermocouple ranges, depends on the prior calibration of one or more voltage ranges. Therefore, to properly calibrate all the input ranges and channels of the AD1B60, perform the following procedure for each step of the calibration sequence:

1. Using the WR_RAM_PARS command, configure the AD1B60 for the appropriate range listed in Table VIII. For example, in the first step of the calibration sequence, set the input range to ±2 V.
2. Apply the reference excitation specified for the input range, listed in Table VIII. For example, in the first step of the calibration sequence, apply a +2.00000 V excitation to channel 0.
3. Issue RD_FPDATA or RD_INTDATA commands and observe the readings. Allow the excitation source to stabilize, and check that the Valid Data flag in the ADSTAT byte is high.
4. Execute the CAL command.
5. Wait until the CAL flag in ADSTAT goes low.
6. Repeat operations 1 through 5 above, using the input ranges and reference excitations, listed in Table VIII, for the next step of the calibration sequence.

Note that you must complete Steps 1 through 8 in Table VIII. However, if your application does not require the attenuator input, you can skip Step 9. If your application does not require thermocouples, you can skip Step 10. If your application does not require RTDs, you can skip Step 11.

RESETTING THE AD1B60

The AD1B60 generates a reset signal (RESETO) at power-up, on detecting a low supply voltage (brown-out), or on missing an internal watchdog pulse. In normal operation, RESETO is tied to the reset input (RESETI). An external active-high reset signal may be used instead of, or in addition to, RESETO. Figure 7 shows how to OR internal and external signals to control RESETI.

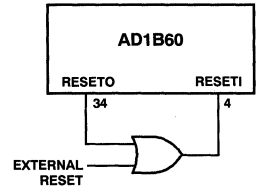

Figure 7. Resetting the AD1B60

Table VIII. Input Ranges and Reference Excitations for Each Iteration of the Calibration Sequence

Step	Input Range	Range Code	Reference Excitation	Channel to Which Reference Excitation Is Applied
1	±2 V	07	+2.00000 V	CH0 to Analog Gnd
2	±1 V	06	+1.00000 V	CH0 to Analog Gnd
3	±500 mV	05	+0.50000 V	CH0 to Analog Gnd
4	±200 mV	04	+0.20000 V	CH0 to Analog Gnd
5	±100 mV	03	+0.10000 V	CH0 to Analog Gnd
6	±50 mV	02	+50.000 mV	CH0 to Analog Gnd

TYPICAL INPUT CONNECTIONS

Thermocouple Input Connections

Figure 8 shows the AD1B60 connections required for a typical, single thermocouple input. In this example, a thermistor CJC sensor is used; the AD1B60 provides the CJC sensor excitation current. The EXCIT output can be used to source current, nominally 10 nA, for open-circuit detection.

Figure 9 shows how four thermocouples may be connected, using a 1 mV/K CJC sensor. All thermocouple inputs must share a common ground.

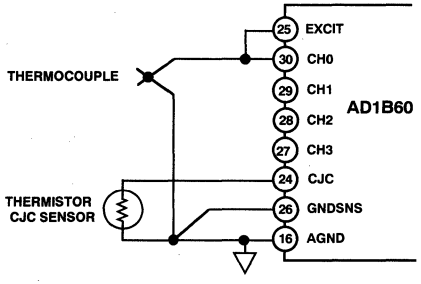

Figure 8. Typical Single-Channel Thermocouple Connection (with Thermistor CJC)

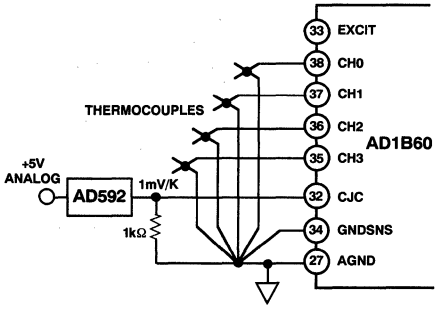

Figure 9. Typical Four-Channel Thermocouple Connection (with AD592 CJC)

Using the CJC Pin as a Digital Output

The CJC pin is normally used as an analog input for cold-junction compensation of thermocouples. When thermistor CJC mode is selected, this pin also outputs an excitation current (nominally 20 μA) for the CJC sensor. In other CJC modes, this output is switched off.

If thermocouples are not being used, the CJC pin may serve as a digital output. This may be especially useful if the AD1B60 is isolated, since providing an isolated control line by other means would be costly.

By placing a 330 kΩ resistor to AGND from this pin, a logic voltage can be generated (see Figure 11). The level can be switched from high (about +4 V) to low (AGND) by changing the CJC mode from thermistor (00) to any other, using the WR_RAM_PARS command.

RTD Input Connections

Typical 3-wire and 4-wire RTD input connections are shown in Figure 10. The EXCIT output supplies 200 μA excitation to the RTD. To maintain high accuracy, lead resistances must match and be less than 20 Ω for 3-wire RTDs, and must be less than 40 Ω for 4-wire RTDs. The 10 kΩ resistor in series with the excitation current source is not required, but will reduce power dissipation and self-heating errors in the AD1B60.

Two RTDs can be multiplexed using the CJC pin as a control line to select between them, as described in the previous subsection. Figures 11 and 12 show multiplexed 3-wire and 4-wire RTDs.

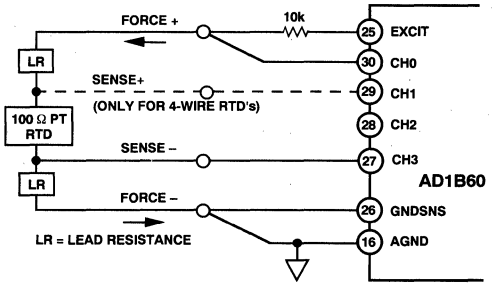

Figure 10. Typical Single-Channel RTD Connection

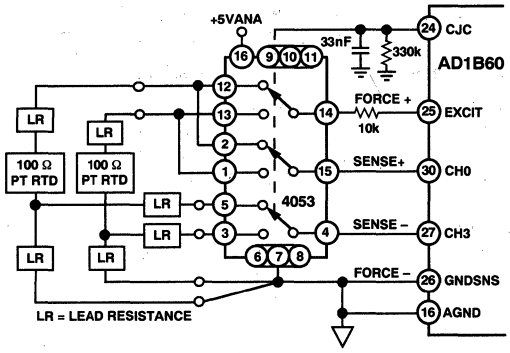

Figure 11. Typical Multiplexed 3-Wire RTD Connection

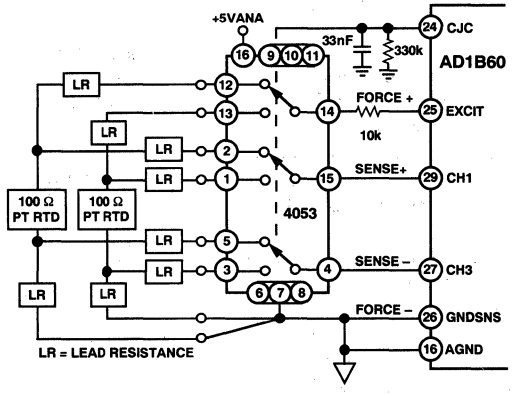

Figure 12. Typical Multiplexed 4-Wire RTD Connection

Low Level Voltage Input Connections

Single channel input connections for low level voltages of up to ±2 V are similar to those of thermocouple input connections, except that no CJC sensor is required. When connecting multiple-channel, low level voltage inputs, all four inputs must share a common ground, as shown in Figure 13. For fastest response when switching between channels, all inputs must share the same input range.

High Level Voltage Input Connections

High level voltages must be connected to the Attenuator pin. An internal 5:1 attenuator scales down high level voltage inputs of ±5 V or ±10 V to levels compatible with the AD1B60's front-end circuitry. Figure 14 shows a typical connection for a high level voltage input.

Input Protection

Inputs that are subject to large transient voltages require protection. For example, inputs should be protected if they connect to sensors through several hundred feet of wiring that may pick up electrical noise or if they may be connected accidentally to power lines. Such inputs should use series resistors to limit input currents and diodes to clamp transient voltages (see Figure 15).

The EXCIT, CH0-CH3, and GNDSNS pins may be subject to large transients and hence may require protection. The ATTEN

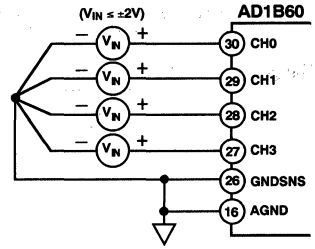

Figure 13. Typical Multiple-Channel Low Level Voltage Input

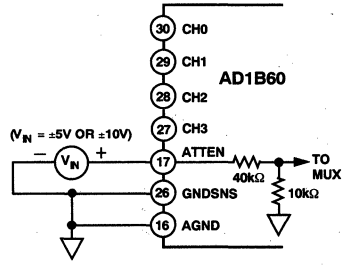

Figure 14. Typical High Level Voltage Input Connection

pin has an internal 40 kΩ resistor, and does not require an external resistor; however, clamp diodes may be required. Generally, the CJC, AGND, and other pins are connected only locally and don't require protection.

Any mismatch in input resistance between an input channel and GNDSNS will be multiplied by the input bias current (3 nA max) and create an apparent input offset voltage. For example, 50 kΩ, 1 % resistors may mismatch by as much as 1 kΩ, resulting in a 3 μV input offset. The resistor used to protect the EXCIT pin may be much larger, since the thermocouple open-circuit detection current is only 10 nA. A 1 MΩ resistor will cause a drop of 10 mV.

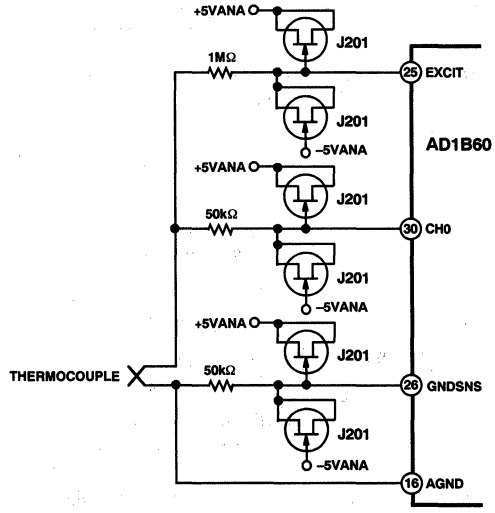

Figure 15. Typical Input Protection Circuitry

The AD1B60 side of the resistors must be clamped to suitable voltages, such as the supply rails (see the Absolute Maximum Ratings). Use low leakage, low capacitance diodes, such as diode-connected J201 JFETs. Note that the diodes' leakage current will flow through the protection resistors and create an offset voltage.

The resistors must be able to withstand the worst-case expected fault voltage, the clamp diodes must be able to pass the worst-case fault current, and the clamp voltages (e.g., the power supplies) must be able to absorb the fault current.

For a fully protected system, you must isolate the AD1B60 from ground. You may do so by using optoisolators on the communications port (RXD and TXD pins) and a dc-to-dc converter for the power supplies.

GENERAL CIRCUIT CONSIDERATIONS

In any system including logic and low level analog signals, care must be taken in the layout and bypassing of the components. Bypass the analog and digital supplies close to the package pins, with a 1.0 μF or 4.7 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor. Keep analog and digital grounds separate except at a single common point. Minimize stray capacitance between digital signals and any analog signal, including analog common. All analog grounds should be connected in a star pattern to a single point.

The integrating capacitor, C_{INT}, should be ceramic and of good quality (X7R dielectric or better). If the synchronous output port is not used, connect CS and CLK to DGND to minimize digital noise.

Figure 16 shows a typical hookup for the default configuration parameters: Type J thermocouple with thermistor CJC and device address 0. The AD232 translates between the TTL levels of the AD1B60 and RS-232 levels for the asynchronous I/O port.

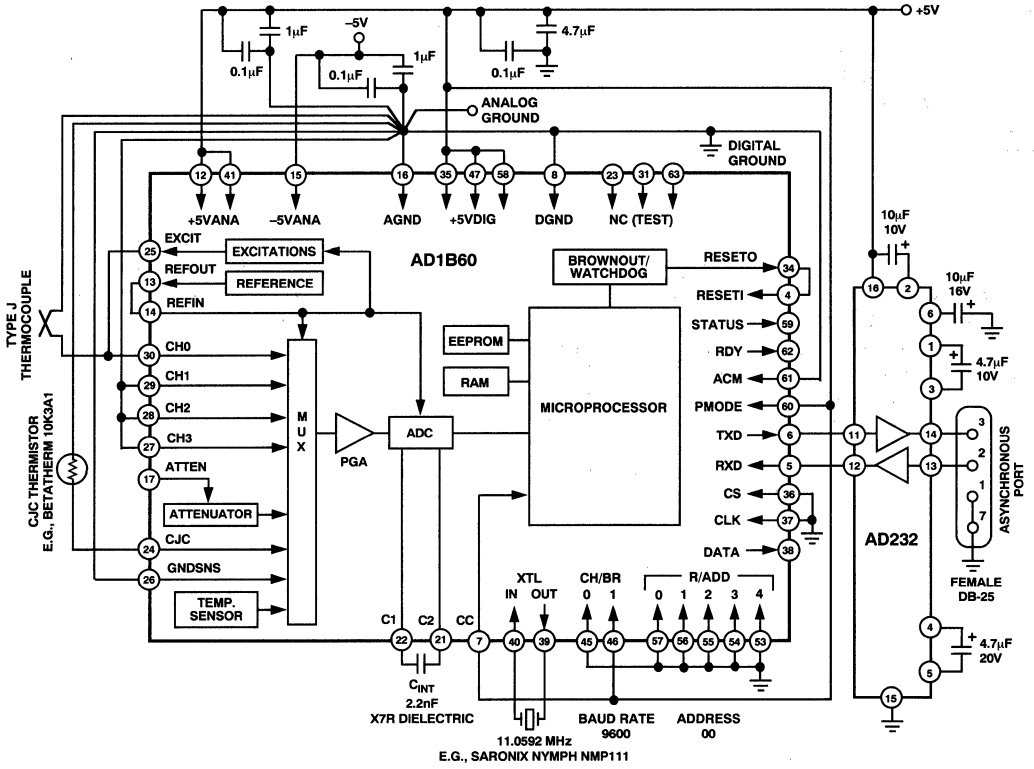

Figure 16. Typical Input and Output Connections for Thermocouple Application

EVALUATION BOARD

The AD1B60/EB evaluation board contains an AD1B60 and support circuitry which allows you to evaluate its functionality and performance using an IBM PC via an asynchronous RS-232 communications port (COM1 or COM2 only).

Included with the evaluation board is an AD1B60BJ device, Evaluation Board User's Manual, 3.5" diskette with the AD1B60 Demonstration Program for PC-DOS and a free copy of the AD1B60 Custom Range Generation Software for Windows.

The menu-driven Demonstration Program allows you to configure and read data from the AD1B60. The Custom Range Generation Software allows generation of user defined ranges specific to your application without additional assistance required from Analog Devices. These range files may be downloaded into the EEPROM of the AD1B60 as required to optimize its performance in your specific application.

16-Bit 500 kHz Sampling ADC

AD1382

PRODUCT FEATURES
Single Package
16-Bit Resolution
500 kHz Sampling Rate
SNR 90 dB @ 100 kHz (min)
THD −88 dB @ 100 kHz (min)
0.0015% FSR INL (typ)

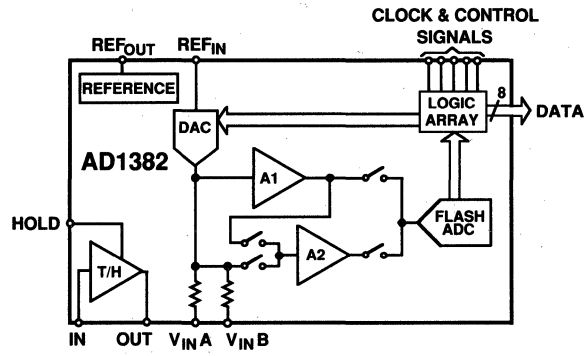
Radar

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1382 is a complete 500 kHz, 16-bit, sampling analog-to-digital converter contained in a single package. This high resolution, high speed converter offers outstanding noise and distortion performance along with excellent INL and DNL performance, all in a single dual-in-line package.

The AD1382 guarantees outstanding noise and distortion performance for both ±5 V and ±10 V input ranges. The AD1382 architecture includes a low noise and low distortion track/hold with a three-pass digitally corrected subranging ADC. Precision thin film resistors and a new proprietary DAC provide for outstanding dynamic and static performance. Output data is multiplexed over an eight-bit CMOS/TTL compatible data bus.

The AD1382 uses four power supplies, ±5 V and ±15 V, and an external 10 MHz clock. Power dissipation is nominally 2.8 W. Two user selectable bipolar input ranges, ±5 V and ±10 V are provided. Careful attention to grounding and a single package make it easy to design PCBs to achieve specified performance.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Integral linearity is inferred from FFT. Differential linearity is derived from histogram.
[2]FSR, full-scale range.
[3]Adjustable to zero.
[4]Noise based on small signal FFT excluding quantization noise.
[5]SNR fundamental to noise minus harmonics 2–9.
[6]THD includes harmonics 2–9 of the fundamental.
[7]Aperture delay is the time from the rising edge on the Hold Command Input to the opening of the switch in the Track/Hold.
[8]Guaranteed but not 100% production tested.
[9]Timing based on 10 MHz clock. Refer to Figures 13 and 14.
[10]Case to ambient temperature is assumed to be 30°C. The AD1382 case temperature will stabilize about 30°C above ambient while operating in free air without a heat sink. Factory calibration is done in this condition. See the application section for further information.

Specifications subject to change without notice.

21	$+V_{S2}$ (+15 V)	28	DNC
22	HOLD COMMAND IN	27	TRACK/HOLD OUTPUT
23	$-V_{S2}$ (−15 V)	26	SIGNAL GROUND
24	POWER GROUND	25	TRACK/HOLD INPUT

DNC = DO NOT CONNECT

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

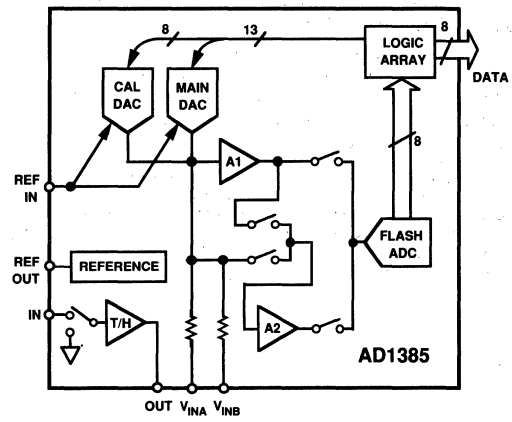
FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1385 is a complete 500 kHz, 16-bit, sampling analog-to-digital converter contained in a single package. Its differential linearity autocalibration feature allows this high resolution, high speed converter to offer outstanding noise and distortion performance, as well as excellent INL and DNL specifications, over the full military temperature range. Autocalibration effectively eliminates DNL drift over temperature.

The AD1385 architecture includes a low noise, low distortion track/hold, a three pass digitally corrected subranging ADC, and linearity calibration circuitry. A complete linearity calibration requires only 15 ms. Precision thin-film resistors and a proprietary DAC contribute to the part's outstanding dynamic and static performance.

The AD1385 uses four power supplies, ±5 V and ±15 V, and an external 10 MHz clock. Power dissipation is nominally 2.76 W. Two user selectable bipolar input ranges, ±5 V and ±10 V, are provided. Careful attention to grounding and a single package make it easy to design PCBs to achieve specified performance.

The AD1385's pinout is nearly identical to that of the AD1382, a factory calibrated 16-bit, 500 kHz SADC. Just two additional connections, to enable and monitor autocalibration, are required. This commonality provides an easy upgrade path to extend system performance and operating temperature range.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Integral linearity is inferred from FFTs. Differential linearity is derived from histograms.
[2]Performance over temperature is specified at the temperature at which the last calibration was performed.
[3]FSR = Full-Scale Range.
[4]Adjustable to zero.
[5]SNR excludes harmonics 2–9 of the fundamental.
[6]THD includes harmonics 2–9 of the fundamental.
[7]Aperture delay is the time from the rising edge on the Hold Command Input to the opening of the switch in the Track/Hold.
Specifications subject to change without notice.

TIMING SPECIFICATIONS[1, 2] (T_A = −55°C to +125°C, V_S = ±15 V, V_{DD} = +5 V, V_{SS} = −5 V)

Parameter	Design Minimum	Typ	Unit	Description
START COMMAND				
t_{SCS}	10		ns	Setup Time
t_{SCH}	10		ns	Hold Time
AUTOZERO				
t_{AZS}	10		ns	Setup Time
t_{AZH}	20		ns	Hold Time
DATA VALID				
t_{DVS}		1.5	CP[3]	Setup Time
t_{DVH}		0.5	CP[3]	Hold Time
HOLD COMMAND				
t_H		13	CP[3]	Hold Time
t_D		7	ns	Delay Time
DATA STROBE				
t_{DS}		2	CP[3]	Pulse Width
t_{DSD}		16.5	CP[3]	Delay
CALIBRATE PULSE WIDTH	20		ns	
CALIBRATION STATUS		15	ms	Duration

NOTE
[1]Refer to Figures 17, 18 and 24.
[2]Design minimums are derived from worst case design analysis and/or simulation results. Typical values are based on characterization data. These specifications are not guaranteed or tested.
[3]The time duration for this parameter varies in direct proportion to the width of the Clock Pulse (CP).

ABSOLUTE MAXIMUM RATINGS*

$+V_S$ to AGND . . . . . 18 V
$-V_S$ to AGND . . . . . −18 V
V_{DD} to PGND . . . . . 7 V
V_{SS} to PGND . . . . . −7 V
AGND to PGND . . . . . ±0.3 V
Analog Inputs . . . . . $\pm V_S$
Reference Input . . . . . 0 V to +11 V
Digital Inputs . . . . . −0.3 V to V_{DD} + 0.3 V
Output Short Circuit Duration
  Reference Output . . . . . Indefinite
  Track/Hold Output . . . . . 1 sec
  Digital Outputs . . . . . 1 sec for Any One Output
Case Temperature (Operating) . . . . . −55°C to +125°C
Storage Temperature . . . . . −65°C to +150°C

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ORDERING GUIDE

Model	Temperature Range (Case)	Package Option*
AD1385KD	0°C to +70°C	DH-48A
AD1385TD	−55°C to +125°C	DH-48A
AD1385TD/883B	−55°C to +125°C	DH-48A

*DH-48A = Bottom Brazed Ceramic DIP. For outline information see Package Information section.

AD1385 PIN CONNECTIONS

The AD1385 is housed in a 48-pin bottom-brazed ceramic bathtub package. The pinout is as follows:

Pin	Function	Pin	Function
1	CLOCK IN	48	V_{DD2} (+5 V POWER)
2	POWER GROUND	47	POWER GROUND
3	B1/B9 (MSB)	46	V_{SS2} (−5 V POWER)
4	B2/B10	45	AUTOZERO
5	B3/B11	44	B1 SELECT
6	B4/B12	43	POWER GROUND
7	B5/B13	42	POWER GROUND
8	B6/B14	41	$\overline{CAL}$
9	B7/B15	40	GAIN ADJUST
10	B8/B16 (LSB)	39	+10 V REFERENCE OUT
11	V_{DD1} (+5 V SIGNAL)	38	$-V_{S1}$ (−15 V)
12	POWER GROUND	37	SIGNAL GROUND
13	V_{SS1} (−5 V SIGNAL)	36	$+V_{S1}$ (+15 V)
14	SIGNAL GROUND	35	SIGNAL GROUND
15	DATA STROBE	34	DNC
16	HI/LO BYTE SELECT	33	DNC
17	$\overline{OE}$ DATA ENABLE	32	+10 V REFERENCE IN
18	START CONVERT	31	V_{IN} B
19	HOLD COMMAND OUT	30	V_{IN} A
20	SIGNAL GROUND	29	OFFSET ADJUST
21	$+V_{S2}$ (+15 V)	28	CAL STATUS
22	HOLD COMMAND IN	27	TRACK/HOLD OUTPUT
23	$-V_{S2}$ (−15 V)	26	SIGNAL GROUND
24	POWER GROUND	25	TRACK/HOLD INPUT

DNC = DO NOT CONNECT

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

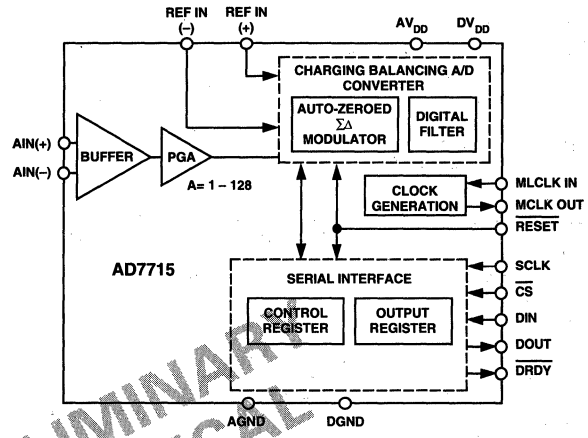
3 V/5 V, Low Cost, Low Power, 16-Bit, Sigma-Delta ADC

AD7715*

FEATURES

Charge-Balancing ADC
16 Bits No Missing Codes
0.0015% Nonlinearity
Programmable Gain Front End
Gains of 1, 2, 32 and 128
Differential Input Capability
Three-Wire Serial Interface
Ability to Buffer the Analog Input
3 V or 5 V Single Supply Operation
Low Supply Current: 500 μA max @ 3 V Supplies
Low-Pass Filter with Programmable Output Update
16-Pin SOIC/DIP

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7715 is a complete analog front end for low frequency measurement applications. The part can accept low level input signals directly from a transducer and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 16 bits of no missing codes performance. The input signal is applied to a proprietary programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and output update rate.

The AD7715 features a differential analog input as well as a differential reference input. It operates from a single supply (+3 V or +5 V). It can handle unipolar input signal ranges of 0 mV to +20 mV, 0 mV to +80 mV, 0 V to +1.25 V and 0 V to +2.5 V. It can also handle bipolar input signal ranges of ±20 mV, ±80 mV, ±1.25 V and ±2.5 V. These bipolar ranges are referenced to the negative input of the differential analog input. The AD7715 thus performs all signal conditioning and conversion for a single-channel system.

The AD7715 is ideal for use in smart, microcontroller or DSP based systems. It features a serial interface which can be configured for three-wire operation. Gain settings, signal polarity and update rate selection can be configured in software using the input serial port. The part contains self-calibration and system calibration options to eliminate gain and offset errors on the part itself or in the system.

CMOS construction ensures very low power dissipation and the power-down mode reduces the standby power consumption to 50 μW typ. The part is available in a 16-pin, 0.3 inch-wide, plastic and hermetic dual-in-line package (DIP) as well as a 16-lead small outline (SOIC) package.

***Protected by U.S. Patent No. 5,134,401.**

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

PRODUCT HIGHLIGHTS

1. The AD7715 consumes less than 500 μA in total supply current at 3 V supplies and 1 MHz master clock, making it ideal for use in low-power systems. Standby current is less than 10 μA.
2. The programmable gain input allows the AD7715 to accept input signals directly from a strain gage or transducer removing a considerable amount of signal conditioning.
3. The AD7715 is ideal for microcontroller or DSP processor applications with a three-wire serial interface reducing the number of interconnect lines and reducing the number of opto-couplers required in isolated systems. The part contains an on-chip registers which allow software control over output update rate, input gain, signal polarity and calibration modes.
4. The part features excellent static performance specifications with 16-bit No Missing Codes, ±0.0015% accuracy and low rms noise (<450 nV). Endpoint errors and the effects of temperature drift are eliminated by on-chip self-calibration, which removes zero-scale and full-scale errors.

AD7715-5—SPECIFICATIONS (AV_{DD} = +5 V, DV_{DD} = +3 V or +5 V, REF IN(+) = +2.5 V; REF IN(–) = AGND; $f_{CLK\ IN}$ = 2.4576 MHz unless otherwise noted. All specifications T_{MIN} to T_{MAX} unless otherwise noted.)

Parameter	A Version[1]	Units	Conditions/Comments
STATIC PERFORMANCE			
No Missing Codes	16	Bits min	Guaranteed by Design, for Filter Notches of 50, 60 Hz
Output Noise	See Tables III & IV		Depends on Filter Cutoffs and Selected Gain
Integral Nonlinearity	±0.0015	% of FSR max	Filter Notches ≤ 60 Hz
Unipolar Offset Error[2]	See Note 3		
Unipolar Offset Drift[4]	2.5/GAIN	µV/°C typ	For Gains of 1 and 2
	0.3	µV/°C typ	For Gains of 32 and 128
Bipolar Zero Error[2]	See Note 3		
Bipolar Zero Drift[4]	2.5/GAIN	µV/°C typ	For Gains of 1 and 2

AV_{DD} Voltage (AD7715-5)	+5	V nom	±5% for Specified Performance
DV_{DD} Voltage	+2.7 to +5.25	V nom	For Specified Performance. AV_{DD} must be ≥ DV_{DD}
Power Supply Currents			
AV_{DD} Current			AV_{DD} = 3 V or 5 V. Gain = 1 to 128 (f_{CLKIN} = 1 MHz) or Gain = 1 or 2 (f_{CLKIN} = 2.4576 MHz)
	0.3	mA max	Typically 0.2 mA. BUF Bit of Setup Register = 0
	0.6	mA max	Typically 0.4 mA. BUF Bit of Setup Register = 1
			AV_{DD} = 3 V or 5 V. Gain = 32 or 128 (f_{CLKIN} = 2.4576 MHz)[17]
	0.5	mA max	Typically 0.3 mA. BUF Bit of Setup Register = 0
	1	mA max	Typically 0.8 mA. BUF Bit of Setup Register = 1
DV_{DD} Current			Digital I/Ps = 0 V or DV_{DD}
	0.2	mA max	Typically 0.15 mA. DV_{DD} = 3 V. $f_{CLK\ IN}$ = 1 MHz
	0.4	mA max	Typically 0.3 mA. DV_{DD} = 5 V. $f_{CLK\ IN}$ = 1 MHz
	0.5	mA max	Typically 0.4 mA. DV_{DD} = 3 V. $f_{CLK\ IN}$ = 2.4576 MHz
	1	mA max	Typically 0.8 mA. DV_{DD} = 5 V. $f_{CLK\ IN}$ = 2.4576 MHz
Power Supply Rejection[18] (AV_{DD})	See Note 19	dB typ	
Normal Mode Power Dissipation			AV_{DD} = DV_{DD} = +3 V. Digital I/Ps = 0 V or DV_{DD}
	1.5	mW max	BUF Bit = 0. All Gains 1 MHz Clock, Gain 1 and 2 @ 2.4576 MHz
	2.4	mW max	BUF Bit = 1. All Gains 1 MHz Clock, Gain 1 and 2 @ 2.4576 MHz
	3	mW max	BUF Bit = 0. Gain = 32 or 128 @ f_{CLKIN} = 2.4576 MHz
	4.5	mW max	BUF Bit = 1. Gain = 32 or 128 @ f_{CLKIN} = 2.4576 MHz
Normal Mode Power Dissipation			AV_{DD} = DV_{DD} = +5 V. Digital I/Ps = 0 V or DV_{DD}
	3.5	mW max	BUF Bit = 0. All Gains 1 MHz Clock, Gain 1 and 2 @ 2.4576 MHz
	5	mW max	BUF Bit = 1. All Gains 1 MHz Clock, Gain 1 and 2 @ 2.4576 MHz
	7.5	mW max	BUF Bit = 0. Gain = 32 or 128 @ f_{CLKIN} = 2.4576 MHz
	10	mW max	BUF Bit = 1. Gain = 32 or 128 @ f_{CLKIN} = 2.4576 MHz
Standby (Power-Down) Dissipation	100	µW max	Typically 50 µW. STBY Bit of Setup Register = 1

NOTES

[1]Temperature ranges are as follows: A Version, –40°C to +85°C.

[2]Applies after calibration at the temperature of interest.

[3]These errors will be of the order of the output noise of the part as shown in Tables III to VI.

[4]Recalibration at any temperature will remove these drift errors.

[5]Positive Full-Scale Error includes Zero-Scale Errors (Unipolar Offset Error or Bipolar Zero Error) and applies to both unipolar and bipolar input ranges.

[6]Full-Scale Drift includes Zero-Scale Drift (Unipolar Offset Drift or Bipolar Zero Drift) and applies to both unipolar and bipolar input ranges.

[7]Gain Error does not include Zero-Scale Errors. It is calculated as Full-Scale Error—Unipolar Offset Error for unipolar ranges and Full Scale Error—Bipolar Zero Error for bipolar ranges.

[8]Gain Drift does not include Unipolar Offset Drift/Bipolar Zero Drift. It is effectively the drift of the part if zero scale calibrations only were performed.

[9]This common-mode voltage range is allowed provided that the input voltage on AIN(+) or AIN(–) does not go more positive than AV_{DD} + 30 mV or go more negative than AGND –30 mV.

[10]These numbers are guaranteed by design and/or characterization.

[11]The analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance depends on the selected gain.

[12]The analog input voltage range on AIN(+) is given here with respect to the voltage on AIN(–). The absolute voltage on the analog inputs should go more positive than go more positive than AV_{DD} + 30 mV or go more negative than AGND – 30 mV.

[13]V_{REF} = REFIN(+) – REFIN(–).

[14]Sample tested at +25°C to ensure compliance.

[15]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale then the device will output all 0s.

[16]These calibration and span limits apply provided the absolute voltage on the analog inputs does not exceed AV_{DD} + 30 mV or go more negative than AGND – 30 mV. The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

[17]Assumes CLK bit of Setup Register is set to correct status corresponding to the master clock frequency.

[18]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 5, 10, 25 or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 6, 10, 30 or 60 Hz.

[19]PSRR depends on gain: Gain of 1: 70 dB typ; Gain of 2: 75 dB typ; Gains of 32 and 128: 85 dB typ.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1, 2] (DV_{DD} = +3 V to +5 V ± 5%; AV_{DD} = +3 V or +5 V ± 5%; AGND = DGND = 0 V; f_{CLKIN} = 2.4576 MHz; Input Logic 0 = 0 V, Logic 1 = DV_{DD} unless otherwise noted)

Parameter	Limit at T_{MIN}, T_{MAX} (A Version)	Units	Conditions/Comments
f_{CLKIN}[3, 4]	400	kHz min	Master Clock Frequency: Crystal Oscillator or Externally Supplied
	2.5	MHz max	for Specified Performance
$t_{CLK\ IN\ LO}$	0.4 × $t_{CLK\ IN}$	ns min	Master Clock Input Low Time. $t_{CLK\ IN}$ = 1/$f_{CLK\ IN}$
$t_{CLK\ IN\ HI}$	0.4 × $t_{CLK\ IN}$	ns min	Master Clock Input High Time
t_r[5]	50	ns max	Digital Output Rise Time. Typically 20 ns
t_f[5]	50	ns max	Digital Output Fall Time. Typically 20 ns

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of DV_{DD}) and timed from a voltage level of 1.6 V.

[2]See Figures 2 and 3.

[3]CLKIN Duty Cycle range is 45% to 55%. CLKIN must be supplied whenever the AD7715 is not in Standby mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7715 is production tested with f_{CLKIN} at 2.4576 MHz (1 MHz for some I_{DD} tests). It is guaranteed by characterization to operate at 400 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross the V_{OL} or V_{OH} limits.

[7]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 100 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.

[8]$\overline{DRDY}$ returns high after the first read from the device after an output update. The same data can be read again, if required, while $\overline{DRDY}$ is high although care should be taken that subsequent reads do not occur close to the next output update.

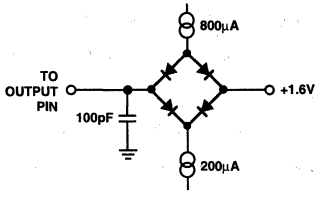

Figure 1. Load Circuit for Access Time and Bus Relinquish

ORDERING GUIDE

Model	AV_{DD} Supply	Temperature Range	Package Option*
AD7715AN-5	5 V	–40°C to +85°C	N-16
AD7715AR-5	5 V	–40°C to +85°C	R-16
AD7715AN-3	3 V	–40°C to +85°C	N-16
AD7715AR-3	3 V	–40°C to +85°C	R-16

*N = Plastic DIP; R = SOIC. For outline information see Package Information section.

ABSOLUTE MAXIMUM RATINGS*

(T_A = +25°C unless otherwise noted)

AV_{DD} to AGND ..... –0.3 V to +7 V
AV_{DD} to DGND ..... –0.3 V to +7 V
DV_{DD} to AGND ..... –0.3 V to +7 V
DV_{DD} to DGND ..... –0.3 V to +7 V
Analog Input Voltage to AGND ..... –0.3 V to AV_{DD} + 0.3 V
Reference Input Voltage to AGND ... –0.3 V to AV_{DD} + 0.3 V
Digital Input Voltage to DGND ..... –0.3 V to DV_{DD} + 0.3 V
Digital Output Voltage to DGND .... –0.3 V to DV_{DD} + 0.3 V
Operating Temperature Range
  Commercial (A Version) ..... –40°C to +85°C
Storage Temperature Range ..... –65°C to +150°C
Junction Temperature ..... +150°C

  Lead Temperature, Soldering
    Vapor Phase (60 sec) ..... +215°C
    Infrared (15 sec) ..... +220°C
Power Dissipation (Any Package) to +75°C ..... 450 mW

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

5

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

TERMINOLOGY

INTEGRAL NONLINEARITY

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full-scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

POSITIVE FULL-SCALE ERROR

Positive full-scale error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal AIN(+) voltage (AIN(–) + V_{REF}/GAIN – 3/2 LSBs). It applies to both unipolar and bipolar analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar offset error is the deviation of the first code transition from the ideal AIN(+) voltage (AIN(–) + 0.5 LSB) when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal AIN(+) voltage (AIN(–) – 0.5 LSB) when operating in the bipolar mode.

GAIN ERROR

This is a measure of the span error of the ADC. It includes full-scale errors but not zero-scale errors. For unipolar input ranges it is defined as (full-scale error–unipolar offset error) while for bipolar input ranges it is defined as (full-scale error–bipolar zero error).

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal AIN(+) voltage (AIN(–) – V_{REF}/GAIN + 0.5 LSB) when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive full-scale overrange is the amount of overhead available to handle input voltages on AIN(+) input greater than AIN(–) + V_{REF}/GAIN (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages on AIN(+) below AIN(–) – V_{REF}/GAIN without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode provided that AIN(+) is greater than AIN(–) and greater than AGND – 30 mV.

OFFSET CALIBRATION RANGE

In the system calibration modes, the AD7715 calibrates its offset with respect to the analog input. The offset calibration range specification defines the range of voltages that the AD7715 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7715 can accept in the system calibration mode and still calibrate full scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7715's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full scale that the AD7715 can accept and still calibrate gain accurately.

PIN FUNCTION DESCRIPTION

Mnemonic	Function
SCLK	Serial Clock. Logic Input. An external serial clock is applied to this input to access serial data from the AD7715. This serial clock can be a continuous clock with all data transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7715 in smaller batches of data.
MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS-compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally either 2.5 MHz or 1 MHz.
MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT. Note, the on-chip clock signal is not available at this pin.
$\overline{\text{RESET}}$	Logic Input. Active low input which resets the control logic, interface logic, digital filter and analog modulator of the part to power-on status.
AIN(+)	Analog Input. Positive input of the programmable gain differential analog input to the AD7715.
AIN(–)	Analog Input. Negative input of the programmable gain differential analog input to the AD7715.
AV_{DD}	Analog Positive Supply Voltage, +3 V nominal (AD7715-3) or +5 V nominal (AD7715-5).
REF IN(–)	Reference Input. Negative input of the differential reference input to the AD7715. The REF IN(–) can lie anywhere between AV_{DD} and AGND provided REF IN(+) is greater than REF IN(–).
REF IN(+)	Reference Input. Positive input of the differential reference input to the AD7715. The reference input is differential with the provision that REF IN(+) must be greater than REF IN(–). REF IN(+) can lie anywhere between AV_{DD} and AGND.
AGND	Ground reference point for analog circuitry.
$\overline{\text{CS}}$	Chip Select. Active low Logic Input used to select the AD7715. With this input hard-wired low, the AD7715 can operate in its three-wire interface mode with SCLK, DIN and DOUT used to interface to the device. $\overline{\text{CS}}$ can be used to select the device in systems with more than one device on the serial bus or as a frame synchronization signal in communicating with the AD7715.
$\overline{\text{DRDY}}$	Logic Output. A logic low on this output indicates that a new output word is available from the AD7715 data register. The $\overline{\text{DRDY}}$ pin will return high upon completion of a read operation of a full output word. If no data read has taken place, after an output update, the $\overline{\text{DRDY}}$ line will return high for $500 \times t_{CLK\ IN}$ cycles prior to the next output update. This gives an indication of when a read operation should not be attempted to avoid reading from the data register as it is being updated. $\overline{\text{DRDY}}$ is also used to indicate when the AD7715 has completed its on-chip calibration sequence.
DOUT	Serial Data Output with serial data being read from the output shift register on the part. This output shift register can contain information from the calibration registers, mode register, communications register, filter selection registers or data register depending on the register selection bits of the communications register.
DIN	Serial Data Input with serial data being written to the input shift register on the part. Data from this input shift register is transferred to the calibration registers, mode register, communications register or filter selection registers depending on the register selection bits of the communications register.
DV_{DD}	Digital Supply Voltage, +3 V or +5 V nominal.
DGND	Ground reference point for digital circuitry.

On-Chip Registers

The part contains four on-chip registers that can be accessed via the serial port on the part. The first of these is a communications register that decides whether the next operation is a read or write operation and also decides which register the read or write operation accesses The communication register also controls the standby mode and calibration modes of the part. The $\overline{DRDY}$ status is also available by reading from the communications register. All communication to any register on the device (including the data register) begins with a write to the communications register. The second register is a setup register that determines filter selection, gain setting and bipolar/unipolar operation. The third register is the data register from which the output data from the part is accessed. The final register is a test register which is accessed when testing the device. It is advised that the user does not attempt to access or change the contents of the test register as it may lead to unspecified operation of the device. The registers are discussed in mode detail in the following sections.

Communications Register (RS1, RS0 = 0, 0)

The communications register is an 8-bit register from which data can either be read or to which data can be written. On power-up or after a $\overline{RESET}$, the part is waiting for a write operation to the communications register. When the part has finished communicating with any of the other registers (either a read or write operation), it returns to the position of expecting a write to the communications register. This is the default state of the interface and in situations where the interface sequence is lost, if enough writes to the device (at least four bytes) take place with DIN high the part returns to its default state. Table I outlines the bit designations for the communications register.

5

Table I. Communications Register

0/$\overline{DRDY}$	0	RS1	RS0	R/$\overline{W}$	STBY	MD1	MD0

0/$\overline{DRDY}$ — For a read operation, this bit provides the status of the $\overline{DRDY}$ flag from the part. The status of this bit is the same as the $\overline{DRDY}$ output pin. For a write operation, a 0 must be written to this bit so that the write operation will be recognized by the register. If a 1 is written to the bit, the interface does not clock itself on and the part continues to sample this bit location, effectively waiting for a 0 before it will proceed to write any data to the communications register.

0 — For a write operation, a 0 *must* be written to this bit for correct operation of the part. Failure to do this will result in unspecified operation of the device. For a read operation, a 0 will be read back from this bit location.

RS1–RS0 — Register Selection Bits. These bits select to which one of four on-chip registers the next read or write operation takes place as follows. When the read or write to the selected register is complete, the part returns to where it is waiting for a write operation to the communications register. It does not remain in a state where it will continue to access the selected register.

RS1	RS0	Register	Register Size
0	0	Communications Register	8 Bit
0	1	Setup Register	8 Bit
1	0	Test Register	8 Bit
1	1	Data Register	16 Bit

R/$\overline{W}$ — Read/Write Select. This bit selects whether the next operation is a read or write operation to the selected register. A 0 indicates a write cycle for the next operation to the appropriate register, while a 1 indicates a read operation from the appropriate register.

STBY — Standby. Writing a 1 to this bit puts the part in its standby or power-down mode. In this mode, the part consumes only 50 μW of power. The part retains its calibration and control word information when in STANDBY. Writing a 0 to this bit places the part in its normal operating mode.

MD1	MD0	**Operating Mode**
0	0	Normal Mode; this is the normal mode of operation of the device whereby the device is performing normal conversions. This is the default condition of these bits after power-on or RESET.
0	1	Self-Calibration; this activates self-calibration on the part. This is a one step calibration sequence and when complete the part returns to normal mode. The $\overline{DRDY}$ output or bit indicates when this self-calibration is complete and a valid word is available in the data register. For this calibration type, the zero-scale calibration is done internally on shorted (zeroed) inputs and the full-scale calibration is done internally on V_{REF}.
1	0	Zero-Scale System Calibration; this activates zero-scale system calibration on the analog input. Calibration is performed on the analog input voltage provided at the analog input during this calibration sequence. The $\overline{DRDY}$ output or bit indicates when this zero-scale calibration is complete and the part returns to normal mode.
1	1	Full-Scale System Calibration; this activates full-scale system calibration on the analog input. Calibration is performed on the analog input voltage provided at the analog input during this calibration sequence. Once again, $\overline{DRDY}$ indicates when this full-scale calibration is complete. When this calibration is complete, the part returns to normal mode.

Setup Register (RS1, RS0 = 0 , 1)
The setup register is an 8-bit register from which data can either be read or to which data can be written. This register controls the setup which the device is to operate in such as the gain, output rate, unipolar/bipolar operation etc. Table II outlines the bit designations for the mode register.

Table II. Setup Register

G1	G0	CLK	FS1	FS0	B/U	BUF	FSYNC

G2	G1	Gain Setting
0	0	1
0	1	2
1	0	32
1	1	128

CLK — Clock Bit. This bit should be set in accordance with the operating frequency of the AD7715. If the device has a master clock frequency of 2.4576 MHz, then this bit should be set to a 0. If the device has a master clock frequency of 1 MHz, then this bit should be set to a 1. This bit sets up the correct scaling currents for a given master clock and also chooses (along with FS1 and FS0) the output update rate for the device. If this bit is not set correctly for the master clock frequency of the device, then the device may not operate to specification.

FS1, FS0 — Filter Selection Bits. Along with the CLK bit, FS1 and FS0 determine the output update rate, filter first notch and –3 dB frequency as below. The on-chip digital filter provides a $Sinc^2$ (or $(Sinx/x)^3$) filter response. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device. Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables III through VI show the effect of the filter notch frequency and gain on the output noise and effective resolution of the part. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 50 Hz, then a new word is available at a 50 Hz rate or every 20 ms. If the first notch is at 500 Hz, a new word is available every 2 ms.

The settling time of the filter to a full-scale step input change is worst case 4 × 1/(output data rate). For example, with the first filter notch at 50 Hz, the settling time of the filter to a full-scale step input change is 80 ms max. If the first notch is at 500 Hz, the settling time of the filter to a full-scale input step is 8 ms max. This settling-time can be reduced to 3 × 1/(output data rate) by synchronizing the step input change to a reset of the digital filter. In other words, if the step input takes place with the $\overline{\text{RESET}}$ input low, the settling time will be 3 × 1/(output data rate) from when $\overline{\text{RESET}}$ returns high.

CLK	FS1	FS0	Output Update Rate	–3 dB Filter Cutoff
0	0	0	50 Hz	13.1 Hz
0	0	1	60 Hz	15.7 Hz
0	1	0	250 Hz	65.5 Hz
0	1	1	500 Hz	121 Hz
1	0	0	20 Hz	5.24 Hz
1	0	1	25 Hz	6.55 Hz
1	1	0	100 Hz	26.2 Hz
1	1	1	200 Hz	52.4 Hz

$\overline{\text{B}}$/U — Bipolar/Unipolar Operation. A 0 in this bit selects bipolar operation. This is the default (Power-On or $\overline{\text{RESET}}$) status of this bit. A 1 in this bit selects unipolar operation.

FSYNC — Filter Synchronization. When this bit is high, the nodes of the digital filter, the filter control logic and the calibration control logic are reset and the analog modulator is also held in its reset state. When this bit goes low, valid data is available in 3 × 1/(output update rate), i.e., the settling time of the filter.

Test Register (RS1, RS0 = 1, 0)
The part contains a test register which is used in testing the device. The user is advised not to change the status of any of the bits in this register from the default (Power-On or RESET) status of all 0s as the part will be placed in one of its test modes and will not operate correctly. If the part enters one of its test modes, exercising $\overline{\text{RESET}}$ will exit the part from the mode.

Data Register (RS1, RS0 = 1, 1)
The data register on the part is a read-only register which contains the most up-to-date conversion result from the part. The register is 16 bits wide. If an attempt is made to write to this register, the data will not actually be written to any location of the part.

OUTPUT NOISE

AD7715-5

Table III shows the AD7715-5 output rms noise for the selectable notch and –3 dB frequencies for the part, as selected by FS1 and FS0 (see above). The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. These numbers are typical and are generated at an analog input voltage of 0 V and for the BUF bit of the setup register = 0. Noise numbers for the two lower notch settings will typically be 10% higher than those in Table III for BUF Bit = 1.

Table IV meanwhile shows the output *peak-to-peak* noise for the selectable notch and –3 dB frequencies for the part. *It is important to note that these numbers represent the resolution for which there will be no code flicker. They are not calculated based on rms noise but on peak-to-peak noise.* The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V and for the BUF bit of the setup register = 0. These numbers are typical, are generated at an analog input voltage of 0 V and are rounded to the nearest LSB.

5

Table III. Output RMS Noise vs. Gain and Output Update Rate for AD7715-5

Filter First Notch & O/P Data Rate		–3 dB Frequency		Typical Output RMS Noise in μV			
MCLK IN = 2.4576 MHz	MCLK IN = 1 MHz	MCLK IN = 2.4576 MHz	MCLK IN = 1 MHz	GAIN = 1	GAIN = 2	GAIN = 32	GAIN = 128

500 Hz	200 Hz	131 Hz	52.4 Hz	10	10	10	10

OUTPUT NOISE

AD7715-3

Table V shows the AD7715-3 output rms noise for the selectable notch and –3 dB frequencies for the part, as selected by FS1 and FS0 (see above). The numbers given are for the bipolar input ranges with a V_{REF} of +1.25 V and for the BUF bit of the setup register = 0. These numbers are typical and are generated at an analog input voltage of 0 V. Noise numbers for the two lower notch settings will typically be 10% higher than those in Table V for BUF Bit = 1.

Table VI meanwhile shows the output *peak-to-peak* noise for the selectable notch and -3 dB frequencies for the part. *It is important to note that these numbers represent the resolution for which there will be no code flicker. They are not calculated based on rms noise but on peak-to-peak noise.* The numbers given are for the bipolar input ranges with a V_{REF} of +1.25 V and for the BUF bit of the setup register = 0. These numbers are typical, are generated at an analog input voltage of 0 V and are rounded to the nearest LSB.

Table V. Output RMS Noise vs. Gain and Output Update Rate for AD7715-3

Filter First Notch & O/P Data Rate		–3 dB Frequency		Typical Output RMS Noise in μV			
MCLK IN = 2.4576 MHz	MCLK IN = 1 MHz	MCLK IN = 2.4576 MHz	MCLK IN = 1 MHz	GAIN = 1	GAIN = 2	GAIN = 32	GAIN = 128

500 Hz	200 Hz	131 Hz	52.4 Hz	11	10	10	9

CIRCUIT DESCRIPTION

The AD7715 is a sigma-delta A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those in industrial control or process control applications. It contains a sigma-delta (or charge-balancing) ADC, a calibration microcontroller with on-chip static RAM, a clock oscillator, a digital filter and a bidirectional serial communications port. The part consumes only 500 μA of power supply current, making it ideal for battery-powered or loop-powered instruments. The part comes in two versions, the AD7715-5 which is specified for operation from a +5 V analog supply (AV_{DD}) and the AD7715-3 which is specified for operation from a +3 V analog supply. The AD7715-5 can be operated with a digital supply (DV_{DD}) voltage of +3 V or +5 V.

The part contains a programmable gain fully differential analog input channel. The selectable gains on this input are 1, 2, 32 and 128 allowing the part to accept unipolar signals of between 0 mV to +20 mV and 0 V to +2.5 V or bipolar signals in the range from ±20 mV to ±2.5 V when the reference input voltage equals +2.5 V. With a reference voltage of +1.25 V, the input ranges are from 0 mV to +10 mV to 0 V to +1.25 V in unipolar mode and from ±10 mV to ±1.25 V in bipolar mode.

The input signal to the analog input is continuously sampled at a rate determined by the frequency of the master clock, MCLK IN, and the selected gain. A charge-balancing A/D converter (Sigma-Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. The programmable gain function on the analog input is also incorporated in this sigma delta modulator with the input sampling frequency being modified to give the higher gains. A $sinc^3$ digital low-pass filter processes the output of the sigma-delta modulator and updates the output register at a rate determined by the first notch frequency of this filter. The output data can be read from the serial port randomly or periodically at any rate up to the output register update rate. The first notch of this digital filter (and hence its –3 dB frequency) can be programmed via the mode register bits FS0 and FS1. With a master clock frequency of 2.4576 MHz, the programmable range for this first notch frequency is from 50 Hz to 500 Hz giving a programmable range for the –3 dB frequency of 13.1 Hz to 131 Hz. With a master clock frequency of 1 MHz, the programmable range for this first notch frequency is from 20 Hz to 200 Hz giving a programmable range for the –3 dB frequency of 5.24 Hz to 52.4 Hz.

DIGITAL INTERFACE

The part's serial interface can operate in three-wire mode by tying the $\overline{CS}$ input low. In this case, the SCLK, DIN and DOUT lines are used to communicate with the part and the status of $\overline{DRDY}$ can be obtained by interrogating the MSB of the communications register. $\overline{CS}$ can be used to decode the part in systems where a number of parts are connected to the serial bus. Figures 2 and 3 show timing diagrams for interfacing to the part with $\overline{CS}$ used to decode the part. Figure 2 is for a read operation from the part's output shift register while Figure 3 shows a write operation to the input shift register.

LC²MOS
22-Bit Data Acquisition System

AD7716

FEATURES

22-Bit Sigma-Delta ADC
- **Dynamic Range of 105 dB (146 Hz Input)**
- **±0.003% Integral Nonlinearity**

On-Chip Low-Pass Digital Filter
- **Cutoff Programmable from 584 Hz to 36.5 Hz**
- **Linear Phase Response**

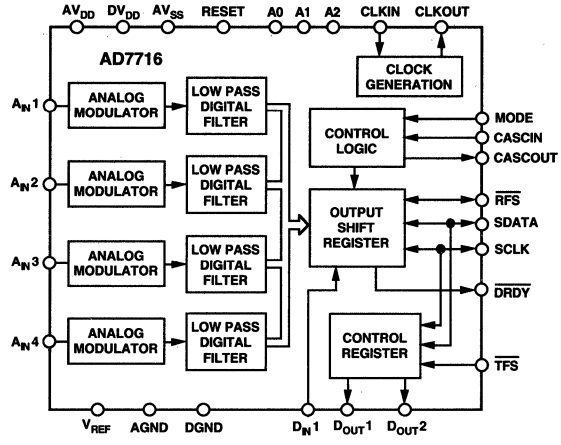
Five Line Serial I/O
Twos Complement Coding
Easy Interface to DSPs and Microcomputers
Software Control of Filter Cutoff
±5 V Supply
Low Power Operation: 50 mW

APPLICATIONS

Biomedical Data Acquisition
- **ECG Machines**
- **EEG Machines**

Process Control
High Accuracy Instrumentation
Seismic Systems

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7716 is a signal processing block for data acquisition systems. It is capable of processing four channels with bandwidths of up to 584 Hz. Resolution is 22 bits and the usable dynamic range varies from 111 dB with an input bandwidth of 36.5 Hz to 99 dB with an input bandwidth of 584 Hz.

The device consists of four separate A/D converter channels that are implemented using sigma-delta technology. Sigma-delta ADCs include on-chip digital filtering and, thus, the system filtering requirements are eased.

Three address pins program the device address. This allows a data acquisition system with up to 32 channels to be set up in a simple fashion. The output word from the device contains 32 bits of data. One bit is determined by the state of the $D_{IN}1$ input and may be used, for example, in an ECG system with an external pacemaker detect circuit to indicate that the output word is invalid because of the presence of a pacemaker pulse.

There are 22 bits of data corresponding to the analog input. Two bits contain the channel address and 3 bits are the device address. Thus, each channel in a 32-channel system would have a discrete 5-bit address. The device also has a CASCOUT pin and a CASCIN pin that allow simple networking of multiple devices.

The on-chip control register is programmed using the SCLK, SDATA and $\overline{TFS}$ pins. Three bits of the Control Register set the digital filter cutoff frequency for the device. Selectable frequencies are 584 Hz, 292 Hz, 146 Hz, 73 Hz and 36.5 Hz. A further 2 bits appear as outputs $D_{OUT}1$ and $D_{OUT}2$ and can be used for controlling calibration at the front end. The device is available in a 44-pin PQFP (Plastic Quad Flatpack) and 44-pin PLCC.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

SPECIFICATIONS[1, 2] (f_{CLKIN} = 8 MHz; MODE Pin Is High (Slave Mode Operation); AV_{DD} = DV_{DD} = +5 V ± 5%; AV_{SS} = –5 V ± 5%; AGND = DGND = 0 V; V_{REF} = 2.5 V; Filter Cutoff = 146 Hz; Noise Measurement Bandwidth = 146 Hz; A_{IN} Source Resistance = 750 Ω[2] with 1 nF to AGND at each A_{IN}. T_A = T_{MIN} to T_{MAX}, unless otherwise noted.)

Parameter	B Version	Units	Test Conditions/Comments
STATIC PERFORMANCE			
Resolution	22	Bits	
Integral Linearity Error	0.003	% FSR typ	Guaranteed No Missed Codes to 21 Bits[3]
	0.006	% FSR max	
Gain Error	1	% FSR max

Power Consumption	50	mW max	35 mW typ
Power Supply Rejection[5]	–70	dB typ	

NOTES
[1]Operating temperature ranges as follows : B Version; –40°C to +85°C.
[2]The A_{IN} pins present a very high impedance dynamic load which varies with clock frequency.
[3]Guaranteed by design and characterization. Digital filter has linear phase.
[4]Usable dynamic range is guaranteed by measuring noise and relating this to the full-scale input range.
[5]100 mV p-p, 120 Hz sine wave applied to each supply.
Specifications subject to change without notice.

Table I. Typical Usable Dynamic Range, RMS Noise and Filter Settling Time vs. Filter Cutoff Frequency

N	Programmed Cutoff Frequency (Hz)	Output Update Rate (Hz)	Usable Dynamic Range (dB)	RMS Noise (μV)	Filter Settling Time to ±0.0007% FS (ms)	Absolute Group Delay (ms)
0	584	2232	99	21	1.35	0.675
1	292	1116	102	14	2.7	1.35
2	146	558	105	10	5.4	2.7
3	73	279	108	7	10.8	5.4
4	36.5	140	111	5	21.6	10.8

NOTE
Usable Dynamic Range is defined as the ratio of the rms full-scale reading (sine wave input) to the rms noise of the converter.

CONTROL REGISTER TIMING CHARACTERISTICS[1, 2] (AV_{DD} = DV_{DD} = +5 V ± 5%; AV_{SS} = –5 V ± 5%; AGND = DGND = 0 V; f_{CLKIN} = 8 MHz; Input Levels: Logic 0 = 0 V, Logic 1 = DV_{DD}; unless otherwise noted)

Parameter	Limit at T_{MIN}, T_{MAX} (B Version)	Units	Conditions/Comments
t_1	$1/f_{CLKIN}$	ns min	SCLK Period
t_2	77	ns min	SCLK Width

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]See Figures 1 and 3.
[3]CLKIN duty cycle range is 40% to 60%.
[4]The AD7716 is production tested with f_{CLKIN} at 8 MHz in the slave mode. It is guaranteed by characterization to operate at 400 kHz and 8 MHz in master mode.
[5]Specified using 10% and 90% points on waveform of interest.
[6]t_{16} is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[7]t_{17} is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Transient currents of up to 100 mA will not cause SCR latch-up.

5

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

ORDERING GUIDE

Model	Temperature Range	Output Noise (Filter: 146 Hz)	Package Option*
AD7716BP	–40°C to +85°C	11 μV rms	P-44
AD7716BS	–40°C to +85°C	11 μV rms	S-44

*P = PLCC (Plastic Leaded Chip Carrier); S = PQFP (Plastic Quad Flatpack). For outline information see Package Information section.

PIN DESCRIPTION

Pin	Description
AV_{DD}	Analog Positive Supply, +5 V Nominal. This supplies +ve power to the analog modulators. AV_{DD} & DV_{DD} must be tied together externally.
DV_{DD}	Digital Positive Supply, +5 V Nominal. This supplies +ve power to the digital filter and input/output registers.
AV_{SS}	Analog Negative Supply, –5 V nominal. This supplies –ve power to the analog modulators.
RESET	A high pulse on this input pin synchronizes the sampling point on the four input channels. It can be used in a multichannel system to ensure simultaneous sampling. This also resets the digital interface to a known state.
A0–A2	The three address input pins, A0, A1 and A2 give the device a unique address. This information is contained in the output data stream from the device.
CLKIN	Clock Input for External Clock.
CLKOUT	Clock Output which is used to generate an internal master clock by connecting a crystal between CLKOUT and CLKIN. If an external clock is used then CLKOUT is not connected.
MODE	This digital input determines the device interface mode. If it is hardwired low, then the Master Mode interface is enabled whereas if it is high, the Slave Mode interface is enabled.
CASCIN	This is an active-high, level-triggered digital input which is used to enable the output data stream. This input may be used to cascade several devices in a multichannel system.
CASCOUT	Digital output which goes high at the end of a complete 4-channel data transfer. This can be connected to the CASCIN of the next device in a multichannel system to ensure proper control of the data transfer.
$\overline{RFS}$	Receive Frame Synchronization signal for the serial output data stream. This can be an input or output depending on the interface mode.
SDATA	Serial Data Input/Output Pin.
SCLK	Serial Clock Input/Output. The SCLK pin is configured as an input or output, depending on the state of the Mode pin.
$\overline{DRDY}$	Data Ready Output. A falling edge indicates that a new word is available for transmission. It will return high when 4, 32-bit words have been transmitted. It also goes high for one clock cycle, when a new word is being loaded into the output register. Data should not be read during this period.
$\overline{TFS}$	Transmit Frame Sync input for programming the on-chip Control Register.
$D_{IN}1$	Digital Data Input. This is contained in the digital data stream sent from the device.
$D_{OUT}1$, $D_{OUT}2$	Digital Outputs. These two digital outputs can be programmed from the on-chip Control Register. They can be used to control calibration signals at the front end.
V_{REF}	Reference Input, Nominally 2.5 V.
AGND	Analog Ground. Ground reference for analog circuitry.
DGND	Digital Ground. Ground return for digital circuitry.
$A_{IN}1$–$A_{IN}4$	Analog Input Pins. The analog input range is ±2.5 V.

TERMINOLOGY

LINEARITY ERROR
This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale (not to be confused with Bipolar Zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

DIFFERENTIAL LINEARITY ERROR/NO MISSED CODES
This is the difference between any code's actual width and the ideal (1 LSB) width. Differential Linearity Error is expressed in LSBs. A differential linearity specification of ±1 LSB or less guarantees no missed codes to the full resolution of the device. The AD7716 has no missed codes guaranteed to 21 bits with a cutoff frequency of 146 Hz.

GAIN ERROR
Gain Error is the deviation of the last code transition (111 . . . 110 to 111 . . . 1) from the ideal (V_{REF} –3/2 LSBs). It is expressed as a percentage of full scale.

GAIN TC
This is the variation of gain error with temperature and is expressed in μV/°C.

OFFSET ERROR
Offset Error is the deviation of the first code transition from the ideal ($-V_{REF}$ + 0.5 LSB). It is expressed as a percentage of full scale.

OFFSET TC
This is the variation of offset error with temperature and is expressed in μV/°C.

NOISE
This is the converter rms noise expressed in μV. Because of the digital filtering in the sigma delta converter, the noise performance is a function of the programmed filter cutoff.

SAMPLING RATE
This is the modulator sampling rate. For the AD7716, it is $f_{CLKIN}/14$.

OUTPUT UPDATE RATE
This is the rate at which the digital filter updates the output shift register. It is a function of the master clock frequency and the programmed filter cutoff frequency.

FILTER CUTOFF FREQUENCY
The digital filter of the AD7716 can be programmed, in binary steps, to 5 discrete cutoff frequencies, ranging from 584 Hz to 36.5 Hz (for a CLKIN frequency of 8 MHz).

SETTLING TIME
This is the settling time of the on-chip digital filter, to 0.0007% of FSR, in response to a full-scale step at the input of the ADC. It is proportional to the master clock frequency and the filter cutoff frequency.

5

USABLE DYNAMIC RANGE
The usable dynamic range is the ratio of the rms full-scale reading (sine wave input) to the rms noise of the converter, expressed in dBs. It determines the level to which it is possible to resolve the input signal. For example, at a bandwidth of 146 Hz, the rms noise of the converter is 11 μV. The full-scale rms is 1.77 volts. So, the usable dynamic range is 104 dB. Any signal below this level will be indistinguishable from noise unless extra post-filtering techniques are employed.

TOTAL HARMONIC DISTORTION
Total harmonic distortion (THD) is the ratio of the rms sum of the harmonics to the fundamental. For the AD7716, it is defined as:

$$THD\ (dB) = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through sixth harmonics.

ABSOLUTE GROUP DELAY
Absolute group delay is the rate of change of phase versus frequency, $d\phi/df$ and is expressed in seconds. For the AD7716, it is dependent on master clock frequency and filter cutoff frequency.

DIFFERENTIAL GROUP DELAY
Differential group delay is the total variation in absolute group delay in the specified bandwidth. Since the digital filter in the AD7716 has perfectly linear phase, the differential group delay is almost zero. This is important in many signal processing applications where excessive differential group delay can cause phase distortion.

GENERAL DESCRIPTION

The AD7716 is a 4-channel 22-bit A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those representing ECG, EEG, chemical, physical or biological processes. It contains four sigma delta ADCs, a clock oscillator and a serial communications port.

Each of the analog input signals to the AD7716 is continuously sampled at a rate determined by the frequency of the master clock, CLKIN. Four sigma-delta modulators convert the sampled signals into digital pulse trains whose duty cycles contain the digital information. These are followed by low-pass filters to process the output of the modulators and update the output register at a maximum rate of 2.2 kHz. The output data can be read from the serial port at any rate up to this.

THEORY OF OPERATION

The general block diagram of a delta-sigma ADC is shown in Figure 5. It contains the following elements.

1. Continuously Sampling Integrator
2. A Differential Amplifier or Subtracter
3. A 1-Bit A/D Converter (Comparator)
4. A 1-Bit DAC
5. A Digital Low-Pass Filter.

In operation, the sampled analog signal is fed to the subtracter, along with the output of the 1-bit DAC. The filtered difference signal is fed to the comparator, whose output samples the difference signal at a frequency many times that of the analog signal frequency (oversampling).

Oversampling is fundamental to the operation of delta-sigma ADCs. Using the quantization noise formula for an ADC:

$$SNR = (6.02 \times number\ of\ bits + 1.76)\ dB,$$

a 1-bit ADC or comparator yields an SNR of 7.78 dB.

When operating with a master clock of 8 MHz, the AD7716 samples the input signal at 570 kHz, which spreads the quantization noise from 0 kHz to 285 kHz. Since the specified analog input bandwidth of the AD7716 is only 584 Hz maximum (it can be programmed to be lower), the noise energy in this bandwidth would be only 1/488 of the total quantization noise, assuming that the noise energy was spread evenly throughout the spectrum. This very high sampling with respect to the input bandwidth is known as oversampling, and the ratio of 488:1 is called the oversampling ratio. The noise is reduced still further by analog filtering in the modulator loop, which shapes the quantization noise spectrum to move most of the noise energy to frequencies above 584 Hz. The SNR performance in the 0 Hz to 584 Hz range is conditioned to the 99 dB level in this fashion (see Table I). As the programmed bandwidth is reduced, the oversampling ratio increases and the usable dynamic range also increases. Thus, for example, with a programmed bandwidth of 73 Hz, the oversampling ratio is 3904:1, and the usable dynamic range is 108 dB which corresponds to greater than 17-bit resolution.

The output of the comparator provides the digital input for the 1-bit DAC, so the system functions as a negative feedback loop which minimizes the difference signal. The digital data that represents the analog input voltage is in the duty cycle of the pulse train appearing at the output of the comparator. It can be retrieved as a parallel binary data word using a digital filter.

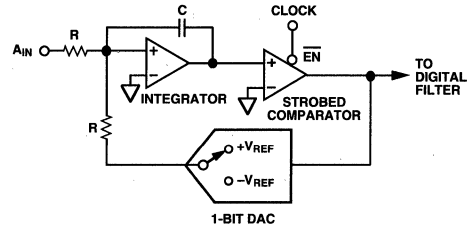

Figure 5. First Order Modulator

Sigma-delta ADCs are generally described by the order of the analog low-pass filter. A simple example of a first order sigma-delta ADC is shown in Figure 5. This contains only a first-order low-pass filter or integrator.

The AD7716 uses a second-order sigma-delta modulator and a digital filter that provides a rolling average of the sampled output. After power-up or if there is a step change in the input voltage, there is a settling time before valid data is obtained.

DIGITAL FILTERING

The AD7716's digital filter behaves like an analog filter, with a few minor differences.

First, since digital filtering occurs after the A-to-D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. If noise signals cause the input signal to exceed the specified range, consideration should be given to analog input filtering, or to reducing the gain in the input channel to bring the combination of signal and noise spike within the specified input range.

Filter Characteristics

The cutoff frequency of the digital filter is determined by bits FC2, FC1 and FC0 in the control register (See Table IV). The cutoff frequency of the filter is $f_{CLKIN}/(3.81 \times 14 \times 256 \times 2N)$, where N is the decimal equivalent of FC2, FC1, FC0. At the maximum clock frequency of 8 MHz, with all 0s loaded to FC2, FC1, FC0, the cutoff frequency of the filter is 584 Hz and the data update rate is 2232 Hz.

Since the AD7716 contains low-pass filtering, there is a settling time associated with step function inputs, and data will be invalid after a step change until the settling time has elapsed. The

relationship between input bandwidth and settling is given in Table I. Because of this settling time, most sigma delta ADCs are unsuitable for high speed multiplexing, where channels are switched and converted sequentially at high rates, as switching between channels can cause a step change in the input. However, the AD7716 is a sigma-delta solution to multichannel applications, since it can process four channels simultaneously. In addition, it is easy to cascade several devices in order to increase the number of channels being processed.

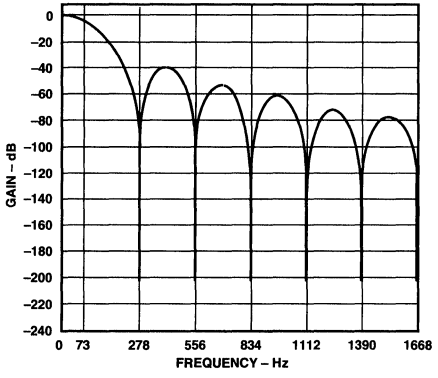

Figure 6. Frequency Response of AD7716 Filter

Figure 6 shows the filter frequency response for a cutoff frequency of 73 Hz. This is a $(\sin x/x)^3$ response (also called sinc^3) that provides greater than 100 dB rejection at the notch frequencies. The relationship between the programmed cutoff frequency and the first notch is constant ($f_{NOTCH} = 3.81 \times f_{CUTOFF}$). The first notch frequency is also the output data rate. The settling time to a full-scale step input is four times the output data period. Programming a different cutoff frequency via FC0–FC2 does not alter the profile of the filter response, it simply changes the frequency of the notches.

In Figure 6, the first notch is at 278 Hz. This is also the output data rate. Settling time to a full-scale step input is 10.8 ms.

The digital filter can be defined by the following equations.

$$H(z) = \left[\frac{1}{N} \times \frac{1 - Z^{-N}}{1 - Z^{-1}}\right]^3$$

$$|H(f)| = \left|\frac{1}{N} \times \frac{\sin(N \times \pi\, f/fs)}{\sin(\pi\, f/fs)}\right|^3$$

where N = Oversampling Ratio

fs = Modulator Sampling Rate

Post Filtering

In the AD7716, the on-chip modulator provides the digital filter with samples at a rate of 570 kHz. The filter decimates these samples to provide data at an output rate which corresponds to the programmed first notch frequency of the filter.

If the user wants to reduce the output noise from the device for bandwidths less than 36.5 Hz, then it is possible to employ extra filtering after the AD7716. This extra digital filtering is called post filtering. If a straight averaging filter is used, for example, a reduction in bandwidth by a factor of 2 results in $\sqrt{2}$ reduction in the rms noise. This additional filtering will also result in a longer settling time.

Antialias Considerations

The digital filter does not provide any rejection at integer multiples of the modulator sampling frequency (n × 570 kHz, where n = 1, 2, 3, . . .). This means that there are frequency bands, $\pm f_{3dB}$ wide (f_{3dB} is the cutoff frequency selected by FC0 to FC2) where noise passes unattenuated to the output. However, due to the AD7716's high oversampling ratio, these bands occupy only a small fraction of the spectrum and most broadband noise is filtered.

In spectral analysis applications, it is important to note that attenuation at half the output update rate is 16 dB. Extra front-end filtering or post filtering may be required to keep aliases in this frequency band at an acceptable level.

USING THE AD7716

SYSTEM DESIGN CONSIDERATIONS

The AD7716 operates differently from successive approximation ADCs or other integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The output register is updated at a rate dependent on the programmed cutoff frequency, and the output can be read at any time.

Input Signal Conditioning

The input range for the AD7716 is $\pm V_{REF}$, where V_{REF} = 2.5 V ± 10%. Other input ranges can be accommodated by input signal conditioning. This may take the form of gain to increase a smaller signal range, or passive attenuation to reduce a larger input voltage range.

Source Resistance

If passive attenuators are used in front of the AD7716, care must be taken to ensure that the source impedance is sufficiently low. The dc input resistance for the AD7716 is greater than 1 GΩ. In parallel with this there is a small sampling capacitor. The dynamic load presented by this varies with the clock frequency. The modulator sampling rate determines the amount of time available for the sampling capacitor to be charged. Any extra external impedances result in a longer overall charge time resulting in extra gain errors on the analog input. The AD7716 has a quite large gain error (1% FSR) due to the fact that there is no on-chip calibration. Thus, even an extra 10 kΩ source resistance and 50 pF source capacitance will have no significant effect on this.

Active signal conditioning circuits such as op amps generally do not suffer from problems of high source impedance. Their open-loop output resistance is normally only tens of ohms and, in any case, most modern general purpose op amps have sufficiently fast closed-loop settling time for this not to be a problem.

Accuracy

Sigma-delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no missing codes performance.

The AD7716 achieves excellent linearity by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient.

Drift Considerations

The AD7716 uses autozeroing techniques to minimize input offset drift. Charge injection in the analog switches and leakage currents at the sampling node are the primary sources of offset voltage drift in the converter. Figure 7 indicates the typical offset due to temperature changes. Drift is relatively flat up to 85°C. Above this temperature, leakage current becomes the main source of offset drift. Since leakage current doubles approximately every 10°C, the offset drifts accordingly. The value of the voltage on the sample capacitor is updated at a rate determined by the master clock, therefore the amount of offset drift which occurs will be proportional to the elapsed time between samples.

Gain drift within the converter depends mainly upon the temperature tracking of the internal capacitors. It is not affected by leakage currents.

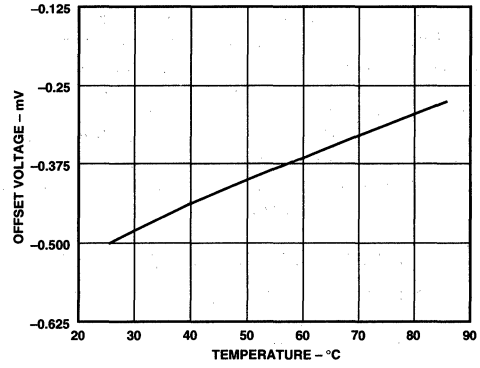

Figure 7. Typical Offset Drift

Voltage Reference

The voltage applied to the V_{REF} pin defines the analog input range. The specified reference voltage is 2.5 V ± 10%.

The reference input presents exactly the same dynamic load as the analog input, but in the case of the reference input, source resistance and long settling time introduce gain errors rather than offset errors. Most precision references however have sufficiently low output impedance and wide enough bandwidth to settle to the required accuracy in the time allowed by the AD7716.

The reference should be chosen to have minimal noise in the programmed passband. Recommended references are the AD780 or the REF43 from Analog Devices. These low noise references have typical noise spectral densities of 100 nV/$\sqrt{\text{Hz}}$ at 600 Hz. This corresponds to an rms noise of 2.5 μV in this band and is more than adequate for the AD7716.

Clock Generation

The device operates from a master clock which must be provided either from a crystal source or an external clock source. If a crystal is used, it must be connected across the CLKIN and CLKOUT pins. Typical loading capacitors of 15 pF are required on CLKIN, CLKOUT. The crystal manufacturers data should be consulted for more information. An external clock can also be used to drive the CLKIN input directly with a CMOS compatible clock. In this case, CLKOUT is left unconnected. The nominal clock frequency for the device is 8 MHz.

CONTROL REGISTER DESCRIPTION

The 16-bit control register is programmed in two 8-bit bytes; the low byte is programmed first and the high byte second. The loading format is LSB first (DB0 for the Least Significant Byte; DB8 for the Most Significant Byte). Three control lines are used: $\overline{TFS}$, SCLK and SDATA. On initial application of power to the AD7716, the control register will come up in an undetermined state. Programming the control register requires an SCLK input, a $\overline{TFS}$ input and an SDATA input. The MODE pin on the device determines whether it is in the master interface mode or the slave interface mode. In either mode, a falling edge on $\overline{TFS}$ causes the part to relinquish control of the SDATA and SCLK lines. When $\overline{TFS}$ goes low, data on the SDATA line is clocked into the control register on each succeeding falling edge of SCLK. When 8 bits have been clocked in, the transfer automatically stops. Only when another negative going edge is detected on $\overline{TFS}$ will new information be written into the control register. The control register programming model is shown in Table II. Bits DB8 and DB0 allow the control register to identify whether the MS Byte or the LS Byte has been programmed. Only when DB8 is a 1 and DB0 is a 0 will the register recognize that a complete valid word has been programmed.

Control register bit, DB15 (A3), acts as an extra address bit which must always be set to 1 to enable programming of the AD7716. If it is set to 0, then the programmed word is ignored. This allows the user to bypass the AD7716 control register and use the serial stream from the DSP or microcomputer to program other serial peripheral devices.

When a valid word has been received, the device interrogates the M0 bit. If this is 0, then the digital filter cutoff frequencies are programmed to the appropriate value if the device address pins correspond to the A2, A1, A0 bits in the control register. If the device address pins do not correspond to the A2, A1, A0 bits then the FC2, FC1, FC0 bits are ignored. If M0 is 1, then the digital filter cutoff frequencies are programmed to the FC2, FC1, FC0 value irrespective of the address bits. In a multichannel system this allows the user to either program all AD7716s to have the same cutoff frequency or else to give each device a separate cutoff frequency.

Control register bits FC2, FC1, FC0 program the digital filter cutoff frequency, see Table VI.

Control register bits D2, D1 control the digital output pins D2 and D1. These are programmed in the same way as FC2, FC1, FC0.

0	0	0	584
0	0	1	292
0	1	0	146
0	1	1	73
1	0	0	36.6

RESET

The AD7716 has a hardware reset which can be used to synchronize many devices. When the RESET pin goes low after being high for at least four CLKIN cycles, the modulator sampling points and digital filter starting points are all synchronized. This synchronizes all devices which receive the RESET pulse and gives simultaneous sampling of all channels. It does not affect the control register but restarts the interface. Also, it is necessary to wait the requisite settling time after applying Reset to get valid data from the device.

CASCADING DEVICES

The AD7716 provides a facility for connecting multiple devices in series. The CASCIN and CASCOUT pins allow this. Connecting CASCOUT to CASCIN of the succeeding device means that the SDATA output of the second device will be disabled until the output register of the first device is empty.

In the case of the first device in the system, it is possible to drive CASCIN from CASCOUT of the last device or, alternatively, invert $\overline{DRDY}$ to drive it. If CASCIN is driven by CASCOUT, then a reset must be applied after every write to the control register. This also applies in single device systems that use CASCOUT to drive CASCIN

DATA OUTPUT INTERFACE MODES

When the control register has been programmed, the device begins conversion. There is an initial delay to allow the digital filters to settle. As already stated, these filters are $Sinc^3$, and so the filter output update rate is directly related to the programmed cutoff frequency. The ratio between these is 3.81. So, for a filter cutoff frequency of 584 Hz, the output update is 2.22 kHz. The falling edge of the $\overline{DRDY}$ output indicates that the output shift register has been updated. There are two interface modes. One is the master mode, where the AD7716 is the master in the system and the processor to which it is communicating is the slave. The other mode is the slave mode, where the AD7716 is the slave and the processor is the system master. In both of these modes the data output stream contains 4×32 bits, corresponding to the four input channels. The output data format is given in Table V. The conversion result DB21–DB0 occupies location DB31–DB10 of the output register. DB21 is the MSB and is transmitted first as shown in the timing diagrams. The channel address is given by CA0 and CA1 which occupy DB9 and DB8 of the output register. The channel address format is given in Table VI.

Master Mode Interface

The device may be placed in the Master Mode by tying the MODE pin low. In this mode, data is clocked out of the AD7716 by an internally generated serial clock and frame synchronization pulse. Two signals initiate the transfer. These are the input CASCIN and the internally generated $\overline{DRDY}$ signal. When a high level is detected on CASCIN, the device checks the state of $\overline{DRDY}$. Note, that on initial power-up or after a reset has been applied, the CASCIN input is not necessary on device 000 for the first data transfer but is required thereafter. If $\overline{DRDY}$ is low, then the 3-state output, $\overline{RFS}$ goes high on the next rising edge of CLKIN and stays high for one CLKIN cycle before going low again. The 3-state SCLK output is also activated on the same rising edge. As $\overline{RFS}$ goes low, DB31 is clocked out on the rising edge of SCLK and is valid on the falling edge of SCLK. Data is transmitted in 8-bit bytes. For each A_{IN}, there are 4, 8-bit bytes and 4 $\overline{RFS}$ pulses. When DB0 of A_{IN} 4 has been clocked out, SCLK goes back into 3-state and the CASCOUT output goes high for one master clock cycle. $\overline{DRDY}$ also goes high at this point. Successive devices can be networked together by tying the CASCOUT of one device to the CASCIN on the next one.

Note that on device 0 (A2, A1, A0 tied low), the CASCIN input should be driven by the inverse of the $\overline{DRDY}$ output. This is shown in the interface diagram of Figure 8.

The Master Mode interface is very suitable for loading data into a serial-to-parallel shift register or for DSPs which can accept a continuous stream of 8-bit bytes.

Slave Mode Interface

The device may be placed in the slave interface mode by tying the MODE pin high. In this mode, the master processor controls the transfer of data from the signal processing block. It starts the transfer by sending a frame synchronizations pulse and serial clock to the AD7716. This could be in response to an interrupt generated by the $\overline{DRDY}$ output on the AD7716. If the device has detected a high level on CASCIN or is device 000 on its first transfer, it starts to send out data on the next rising edge of SCLK. This data is then valid on the falling edge of SCLK. When all the data bits have been clocked out, the CASCOUT pin goes high for one CLKIN cycle and $\overline{DRDY}$ also goes high. The slave mode interface is suited to both microcomputers like the 8051 and 68HC11 and also DSPs like the TMS320C25, ADSP-2101 family and the DSP56000 family.

MICROPROCESSOR INTERFACING

Interfacing the AD7716 to the ADSP-2100 Family

The ADSP-2100 family of microcomputers from Analog Devices are high speed, high performance digital signal processors. Many members of the family have serial ports (known as SPORTs) which are compatible with the AD7716. These include the ADSP-2101, ADSP-2105, ADSP-2111 and ADSP-2115. Full details of these are available in the *ADSP-2100 Family User's Manual* available from Analog Devices.

Figure 8 shows the hardware interface between two AD7716s and SPORT 0 of the ADSP-2101 DSP. This yields a very efficient 8-channel data acquisition system. The AD7716 is set up for slave interface mode by tying the MODE pin high. This means that the ADSP-2101 is the master in the system and supplies the necessary frame synchronization and SCLK Signals to the AD7716s when writing to and reading from the device.

On power up, the user should write to the AD7716 control register in order to set the filter cutoff frequencies. The appropriate SPORT 0 Control Register (0 × 3FF6) setting is "7EC7." This sets the transmit section for alternate inverted framing with a word length of 8 bits. Two 8-bit words should then be written to each AD7716 to program the filter cutoff frequencies. The control register programming model is given in Table II. Note that the LSB (DB0) must be loaded first as in the timing diagram of Figure 2.

When the write operation is complete, a reset pulse should be applied to both devices. This ensures that the sampling and interface timing of the device are synchronized. The reset can be under DSP control, in which case a flag output could be used.

After reset, the processor should jump to the read routine. For this read routine, there are several registers that need to be set.

The SPORT0 Control Register setting is "7FCF." This sets the receive section for internal SCLK, continuous receive with alternate inverted framing.

The SPORT0 SCLKDIV Register (0 × 3FF5) determines the SCLK frequency from the ADSP-2101. With "0000" loaded, the SCLK output is at its maximum (1/2 the master clock of 12.5 MHz).

In normal operation, a SPORT generates an interrupt when it has received a data word. Autobuffering provides a mechanism for receiving or transmitting an entire block of serial data before an interrupt is generated. Service routines can operate on the entire block of data, rather than on a single word, reducing overhead significantly. This is ideal for use with a device like the AD7716 where there is a requirement to read many bits of data (256 in this case) for each sampling instant. The SPORT0 Autobuffer Control Register (0 × 3FF3) is loaded with "0001" to enable the Receive Autobuffering.

The SPORT0 RFSDIV Register (0 × 3FF4) should be set to the minimum value of "000F." Finally the IRQ2 interrupt should be enabled.

The DSP will now wait for an interrupt from the AD7716. This interrupt is generated by the AD7716 $\overline{\text{DRDY}}$ line going low. If the interrupt service routine is set for autobuffered mode with a length of 16 (16-bit) words, then the DSP will read in the 256 bits from the two AD7716s in one continuous stream and then stop. The data from the two devices will be contained in the designated data memory area and the DSP can now go and operate on this as is necessary. Note that, because of the ADSP-2101 framing, a one-bit shift left will be necessary on the data in memory. For 16 data words, this will require 22 instruction cycles.

+5 V Only
Half-Scale Conversion Option
Fast Interface Port
Power-Down Mode

APPLICATIONS
HDD Servos
Instrumentation

GENERAL DESCRIPTION

The AD7776, AD7777 and AD7778 are a family of high speed, multichannel, 10-bit ADCs primarily intended for use in R/W head positioning servos found in high density hard disk drives. They have unique input signal conditioning features which make them ideal for use in such single supply applications.

By setting a bit in a control register within both the four-channel version, AD7777, and eight-channel version, AD7778, the input channels can either be independently sampled or any two channels of choice can be simultaneously sampled. For all versions the specified input signal range is of the form $V_{BIAS} \pm V_{SWING}$. However, if the RTN pin is biased at, say, 2 V then the analog input signal range becomes 0 V to +2 V for all input channels. This is dealt with in more detail under the section Changing the Analog Input Voltage Range. The voltage V_{BIAS} is the offset of the ADC's midpoint code from ground and is supplied either by an onboard reference available to the user (REFOUT) or by an external voltage reference applied to REFIN. The full-scale range (FSR) of the ADC is equal to 2 V_{SWING} where V_{SWING} is nominally equal to REFIN/2. Additionally, when placed in the half-scale conversion mode, the value of REFIN is converted. This allows the channel offset(s) to be measured.

Control register loading and ADC register reading, channel select and conversion start are under the control of the μP. The twos complemented coded ADCs are easily interfaced to a standard 16-bit MPU bus via their 10-bit data port and standard microprocessor control lines.

They are fabricated in linear compatible CMOS (LC²CMOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The AD7776 is available in a 24-pin SOIC package; the AD7777 is available in both 28-pin DIP and 28-pin SOIC packages; the AD7778 is available in a 44-pin PQFP package.

*Protected by U.S. Patent No. 4,990,916.

NOTES
[1]See Figures 1 to 3.
[2]Timing specifications in bold print are 100% production tested. All other times are guaranteed by design, not production tested. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[3]t_4 is measured with the load circuit of Figure 4 and defined as the time required for an output to cross 0.8 V or 2.4 V.
[4]t_5 is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 4. The measured time is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time t_5 quoted above is the true bus relinquish time of the device and, as such, is independent of the external bus loading capacitance.
Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

5

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V, which readily accumulate on the human body and on test equipment, can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper precautions are recommended to avoid any performance degradation or loss of functionality.

ORDERING GUIDE

Model	Temperature Range	No. of Channels	Package Option[1, 2]
AD7776AR[3]	−40°C to +85°C	1	R-24
AD7777AN	−40°C to +85°C	4	N-28
AD7777AR[3]	−40°C to +85°C	4	R-28
AD7778AS[3]	−40°C to +85°C	8	S-44

NOTES
[1]R = SOIC, N = Plastic DIP, S = PQFP.
[2]For outline information see Package Information section.
[3]Analog Devices reserves the right to ship devices branded with a J in place of the A, e.g., AD7776JR instead of AD7776AR. Temperature range remains −40°C to +85°C.

PIN FUNCTION DESCRIPTION

Mnemonic	Description
V_{CC}	+5 V Power Supply.
AGND	Analog Ground.
DGND	Digital Ground. Ground reference for digital circuitry.
DB0–DB9	Input/Output Data Bus. This is a bidirectional data port from which ADC output data may be read and to which control register data may be written.
$\overline{BUSY}/\overline{INT}$	Busy/Interrupt Output. Active low logic output indicating A/D converter status. This logic output has two modes of operation depending on whether location CR9 of the control register has been set low or high: If CR9 is set low, then the $\overline{BUSY}/\overline{INT}$ output will behave as a $\overline{BUSY}$ signal. The $\overline{BUSY}$ signal will go low and stay low for the duration of a single conversion, or if simultaneous sampling has been selected, $\overline{BUSY}$ will stay low for the duration of both conversions. If CR9 is set high, then the $\overline{BUSY}/\overline{INT}$ output behaves as an INTERRUPT signal. The $\overline{INT}$ signal will go low and remain low after either a single conversion is completed or after a double conversion is completed if simultaneous sampling has been selected. With CR9 high, the falling edge of $\overline{WR}$ or $\overline{RD}$ resets the $\overline{INT}$ line high.
$\overline{CS}$	Chip Select Input. The device is selected when this input is low.
$\overline{WR}$	Write Input (Active Low). It is used in conjunction with $\overline{CS}$ to write data to the control register. Data is latched to the registers on the rising edge of $\overline{WR}$. Following the rising edge of $\overline{WR}$, the analog input is acquired and a conversion is started.
$\overline{RD}$	Read Input (Active Low). It is used in conjunction with $\overline{CS}$ to enable the data outputs from the ADC registers.
$A_{IN}1$–8	Analog Inputs 1–8. The analog input range is $V_{BIAS} \pm V_{SWING}$ where V_{BIAS} and V_{SWING} are defined by the reference voltage applied to REFIN. Input resistance between any of the analog input pins and AGND is 10 kΩ or greater.
REFIN	Voltage Reference Input. The AD7776/AD7777/AD7778 are specified over a voltage reference range of 1.9 V to 2.1 V with a nominal value of 2.0 V. This REFIN voltage provides the V_{BIAS} and V_{SWING} levels for the input channel(s). V_{BIAS} is equal to REFIN and V_{SWING} is nominally equal to REFIN/2. Input resistance between this REFIN pin and AGND is 10 kΩ or greater.
REFOUT	Voltage Reference Output. The internal voltage reference, which is nominally 2.0 V and can be used to provide the bias voltage (V_{BIAS}) for the input channel(s), is provided at this pin.
C_{REFIN}	Reference Decoupling Capacitor. A 10 nF capacitor must be connected from this pin to AGND to ensure correct operation of the high speed ADC.
RTN	Signal Return Path for the input channel(s). Normally RTN is connected to AGND at the package.

CIRCUIT DESCRIPTION

ADC Transfer Function

For all versions, an input signal of the form $V_{BIAS} \pm V_{SWING}$ is expected. This V_{BIAS} signal level operates as a psuedo ground to which all input signals must be referred. The V_{BIAS} level is determined by the voltage applied to the REFIN pin. This can be driven by an external voltage source; or, alternatively, the onboard 2 V reference, available at REFOUT, can be used. The magnitude of the input signal swing is equal to $V_{BIAS}/2$ (or REFIN/2) and is set internally. With a REFIN of 2 V, the analog input signal level varies from 1 V up to 3 V i.e., 2 ± 1 V. Figure 5 shows the transfer function of the ADC and its relationship to V_{BIAS} and V_{SWING}. The half-scale twos complement code of the ADC, 000 Hex (00 0000 0000 Binary), occurs at an input voltage equal to V_{BIAS}. The input full-scale range of the ADC is equal to 2 V_{SWING}, so that the Plus Full-Scale transition (1FE to 1FF) occurs at a voltage equal to $V_{BIAS} + V_{SWING} -$ 1.5 LSBs and the minus full-scale code transition (200 to 201) occurs at a voltage $V_{BIAS} - V_{SWING} + 0.5$ LSBs.

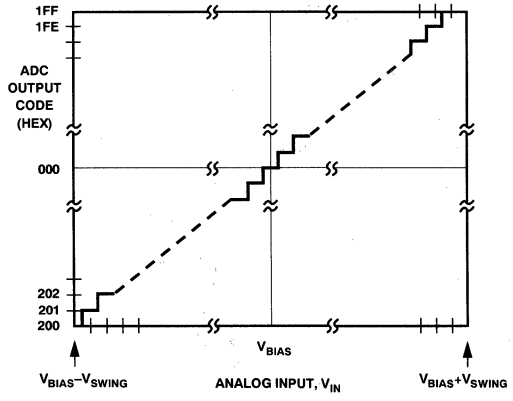

Figure 5. ADC Transfer Function

CONTROL REGISTER

The control register is 10-bits wide and can only be written to. On power-on, all locations in the control register are automatically loaded with 0s. For the single channel AD7776, locations CR0 to CR6 of the control register are "don't cares." For the quad channel AD7777, locations CR2 and CR5 are "don't cares." Individual bit functions are described below.

CR0–CR2: Channel Address Locations. Determines which channel will be selected and converted for single channel operation. For simultaneous sampling operation CR0–CR2 holds the address of one of the two channels to be sampled.

AD7776

CR2	CR1	CR0	Function
X*	X	X	Select $A_{IN}1$

*X = Don't Care

AD7777

CR2	CR1	CR0	Function
X*	0	0	Select $A_{IN}1$
X	0	1	Select $A_{IN}2$
X	1	0	Select $A_{IN}3$
X	1	1	Select $A_{IN}4$

*X = Don't Care

AD7778

CR2	CR1	CR0	Function
0	0	0	Select $A_{IN}1$
0	0	1	Select $A_{IN}2$
0	1	0	Select $A_{IN}3$
0	1	1	Select $A_{IN}4$
1	0	0	Select $A_{IN}5$
1	0	1	Select $A_{IN}6$
1	1	0	Select $A_{IN}7$
1	1	1	Select $A_{IN}8$

CR3–CR5: Channel Address Locations. Only applicable for simultaneous sampling with the AD7777 or AD7778 when CR3–CR5 holds the address of the second channel to be sampled.

AD7777

CR5	CR4	CR3	Function
X*	0	0	Select $A_{IN}1$
X	0	1	Select $A_{IN}2$
X	1	0	Select $A_{IN}3$
X	1	1	Select $A_{IN}4$

*X = Don't Care

AD7778

CR5	CR4	CR3	Function
0	0	0	Select $A_{IN}1$
0	0	1	Select $A_{IN}2$
0	1	0	Select $A_{IN}3$
0	1	1	Select $A_{IN}4$
1	0	0	Select $A_{IN}5$
1	0	1	Select $A_{IN}6$
1	1	0	Select $A_{IN}7$
1	1	1	Select $A_{IN}8$

CR6: Determines whether operation is on a single channel or simultaneous sampling on two channels. Location CR6 is a "don't care" for the AD7776.

CR6	Function
0	Single channel operation. Channel select address is contained in locations CR0–CR2.
1	Two channels simultaneously sampled and sequentially converted. Channel select addresses contained in locations CR0–CR2 and CR3–CR5.

CR7: Determines whether the device is in the normal operating mode or in the half-scale test mode.

CR7	Function
0	Normal Operating Mode
1	Half-Scale Test Mode

In the half-scale test mode REFIN is internally connected as an analog input(s). In this mode locations CR0-CR2 and CR3-CR5 are all "don't cares" since it is REFIN which will be converted. For the AD7777 and AD7778, the contents of location CR6 still determine whether a single or a double conversion is carried out on the REFIN level.

CR8: Determines whether the device is in the normal operating mode or in the power-down mode.

CR8	Function
0	Normal Operating Mode
1	Power-down Mode

In the power-down mode all linear circuitry is turned off and the REFOUT output is pulled weakly (5 kΩ) to AGND. The input impedance of the analog inputs and of the REFIN input remains the same in either normal mode or power-down mode. See under Circuit Description – Power-Down Mode.

CR9: Determines whether $\overline{\text{BUSY}}/\overline{\text{INT}}$ output flag goes low and remains low during conversion(s) or else goes low and remains low after the conversion(s) is (are) complete.

CR9	$\overline{\text{BUSY}}/\overline{\text{INT}}$ Functionality
0	Output goes low and remains low during conversion(s).
1	Output goes low and remains low after conversion(s) is (are) complete.

ADC Conversion Start Timing

Figure 6 shows the operating waveforms for the start of a conversion cycle. On the rising edge of $\overline{\text{WR}}$, the conversion cycle starts with the acquisition and tracking of the selected ADC channel, $A_{IN}1$–8. The analog input voltage is held 40 ns (typically) after the first rising edge of CLKIN following four complete CLKIN cycles. If t_D in Figure 6 is greater than 12 ns, then the falling edge of CLKIN as shown will be seen as the first falling clock edge. If t_D is less than 12 ns, the first falling clock edge to be recognized will not occur until one cycle later.

Following the "hold" on the analog input(s), two complete CLKIN cycles are allowed for settling purposes before the MSB decision is made. The actual decision point occurs approximately 40 ns after the rising edge of CLKIN as shown in Figure 6. A further two CLKIN cycles are allowed for the second MSB decision. The succeeding bit decisions are made approximately 40 ns after each rising edge of CLKIN until the conversion is complete. At the end of conversion, if a single conversion has been requested (CR6 = 0), the $\overline{\text{BUSY}}/\overline{\text{INT}}$ line changes

state (as programmed by CR9), and the SAR contents are transferred to the first register ADCREG1. The SAR is then reset in readiness for a new conversion. If simultaneous sampling has been requested (CR6 = 1), no change occurs in the status of the $\overline{BUSY/INT}$ output and the ADC automatically starts the second conversion. At the end of this conversion the $\overline{BUSY/INT}$ line changes state (as programmed by CR9) and the SAR contents are transferred to the second register, ADCREG2.

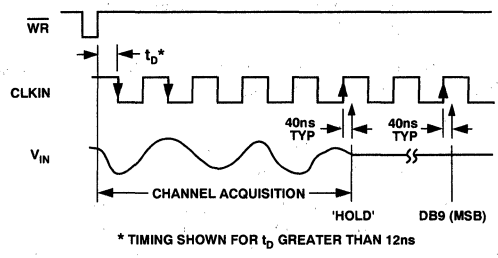

Figure 6. ADC Conversion Start Timing

Track-and-Hold

The track-and-hold (T/H) amplifiers on the analog input(s) of the AD7776/AD7777/AD7778 allow the ADC to accurately convert an input sine wave of 2 V peak-peak amplitude up to a frequency of 189 kHz, the Nyquist frequency of the ADC when operated at its maximum throughput rate of 378 kHz. This maximum rate of conversion includes conversion time and time between conversions. Because the input bandwidth of the track-and-hold is much greater than 189 kHz, the input signal should be band limited to avoid folding unwanted signals into the band of interest.

Power-Down

The AD7776/AD7777/AD7778 can be placed in a power-down mode simply by writing a logic high to location CR8 of the control register. The following changes are effected immediately on writing a "1" to location CR8:

- Any conversion that is in progress is terminated.
- If a conversion is in progress, then the leading edge of $\overline{WR}$ immediately drives the $\overline{BUSY/INT}$ output high.
- All the linear circuitry is turned off.
- The REFOUT output stops being driven and is pulled weakly (5 kΩ) to analog ground.

Control inputs $\overline{CS}$, $\overline{WR}$ and $\overline{RD}$ retain their purpose while the AD7776/AD7777/AD7778 is in power-down. If no conversions are in progress when the AD7776/AD7777/AD7778 is placed into the power-down modes, the contents of the ADC registers, ADCREG1 and ADCREG2, are retained during power-down and can be read as normal. On returning to normal operating mode a new conversion (or conversions, dependent on CR6) is automatically started. On completion, the invalid conversion results are loaded into the ADC registers losing the previous valid results.

In order to achieve the lowest possible power consumption in the power-down mode special attention must be paid to the state of the digital and analog inputs and outputs:

- Because each analog input channel sees a resistive divider to AGND, the input resistance of which does not change between normal and power-down modes, driving the analog input signals to 0 V or as close as possible to 0 V will minimize the power dissipated in the input signal conditioning circuitry.
- Similarly, the REFIN input sees a resistive divider to AGND, the input resistance of which does not change between normal and power-down modes. If an external reference is being used, then driving this reference input to 0 V or as close as possible to 0 V will minimize the power dissipated in the input signal conditioning circuitry.
- Since the REFOUT pin is pulled to AGND via, typically, a 5 kΩ resistor, any voltage above 0 V that this output may be pulled to by external circuitry will dissipate unnecessary power.
- Digital inputs $\overline{CS}$, $\overline{WR}$ & $\overline{RD}$ should all be held at V_{CC} or as close as possible. CLKIN should be held as close as possible to either 0 V or V_{CC}.
- Since the $\overline{BUSY/INT}$ output is actively driven to a logic high, any loading on this pin to 0 V will dissipate power.

The AD7776/AD7777/AD7778 comes out of the power-down mode when a Logic "0" is written to location CR8 of the control register. Note that the contents of the other locations in the control register are retained when the device is placed in power-down and are valid when power is restored. However coming out of power-down provides an opportunity to reload the complete contents of the control register without any extra instructions.

Microprocessor Interfacing Circuits

The AD7776/AD7777/AD7778 family of ADCs is intended to interface to DSP machines such as the ADSP-2101, ADSP-2105, the TMS320 family and microcontrollers such as the 80C196 family.

Figure 7 shows the AD7776/AD7777/AD7778 interfaced to the TMS320C10 @ 20.5 MHz and the TMS320C14 @ 25 MHz. Figure 8 shows the interface with the TMS320C25 @ 40 MHz. Note that one wait state is required with this interface. The ADSP-2101-50 and the ADSP-2105-40 interface is shown in Figure 9. One wait state is required with either of these machines.

Figure 10 shows the interface with the 80C196KB @ 12 MHz and the 80C196KC @ 16 MHz. One wait state is required with the 16 MHz machine. The 80C196 is configured to operate with a 16-bit multiplexed address/data bus.

Table I gives a truth table for the AD7776/AD7777/AD7778 and summarizes their microprocessor interfacing features. Note that a read instruction to any of the devices while a conversation is in progress will immediately stop that conversion and return unreliable data over the data bus.

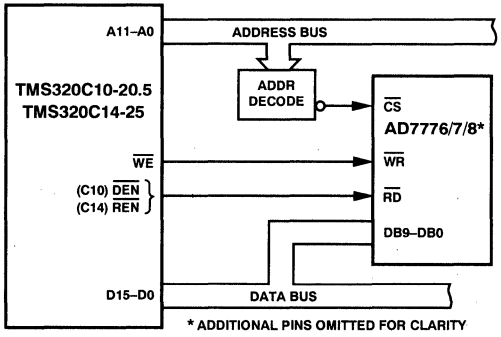

Figure 7. AD7776/AD7777/AD7778 to TMS320C10 and TMS320C14 Interface

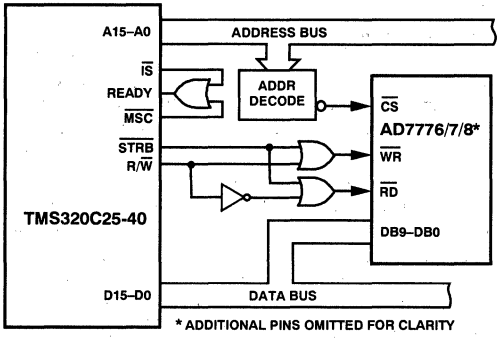

Figure 8. AD7776/AD7777/AD7778 to TMS320C25 Interface

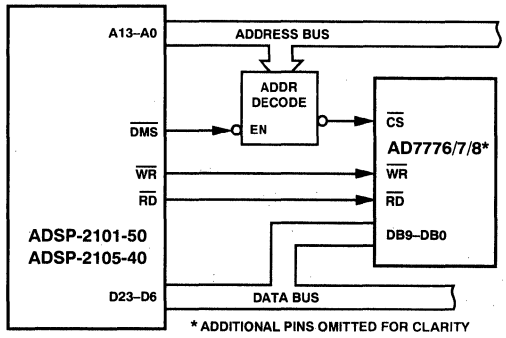

Figure 9. AD7776/AD7777/AD7778 to ADSP-2101 and ADSP-2105 Interface

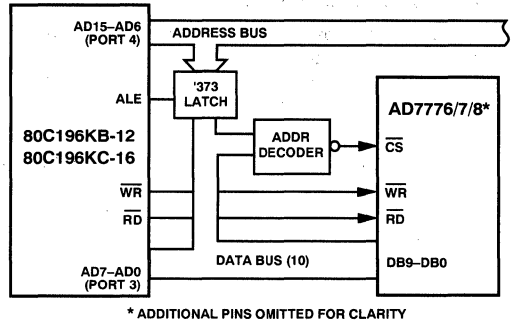

Figure 10. AD7776/AD7777/AD7778 to 80C196 Interface

Table I. AD7776/AD7777/AD7778 Truth Table for Microprocessor Interfacing

$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	DB0–DB9	Function/Comments
1	X*	X*	High Z	Data Port High Impedance
0	1	↓	CR Data	Load control register (CR) data to control register and start a conversion.
0	↓	1	ADC Data	ADC data placed on data bus. Depending upon location CR6 of the control register, one or two Read instructions will be required.
				If CR6 is low, i.e., single channel conversion selected, a read instruction returns the contents of ADCREG1. Succeeding read instructions continue to return the contents of ADCREG1.
				If CR6 is high, i.e., simultaneous sampling (double conversion) selected, the first read instruction returns the contents of ADCREG1 while the second read instruction returns the contents of ADCREG2. A third read instruction returns ADCREG1 again, the fourth ADCREG2, etc.

*X = Don't Care

DESIGN INFORMATION

Layout Hints

Ensure that the layout for the printed circuit board has the digital and analog grounds separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog input(s) with RTN.

Establish a single point analog ground separate from the logic system ground and as close as possible to the AD7776/AD7777/AD7778. Both the RTN and AGND pins on the AD7776/AD7777/AD7778 and all other signal grounds should be connected to this single point analog ground. In turn, this star ground should be connected to the digital ground at one point only—preferably at the low impedance power supply itself.

Low impedance analog and digital power supply common returns are important for correct operation of the devices, so make the foil width for these tracks as wide as possible.

In order to ensure a low impedance +5 V power supply at the actual V_{CC} pin, it will be necessary to employ bypass capacitors from the pin itself to DGND. A 4.7 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor is sufficient.

ADC Corruption

Executing a read instruction to the AD7776/AD7777/AD7778 while a conversion is in progress will immediately halt the conversion and return invalid data over the data bus. The $\overline{BUSY}$/$\overline{INT}$ output pin should be monitored closely and all read instructions to the AD7776/AD7777/AD7778 prevented while this output shows that a conversion is in progress.

Executing a write instruction to the AD7776/AD7777/AD7778 while a conversion is in progress immediately halts the conversion, the falling edge of $\overline{WR}$ driving the $\overline{BUSY}$/$\overline{INT}$ output high. The analog input(s) is sampled as normal and a new conversion sequence (dependent upon CR6) is started.

ADC Conversion Time

Although each conversion takes only 14 CLKIN cycles, it can take between 4.5 to 5.5 CLKIN cycles to acquire the analog input(s) after the $\overline{WR}$ input goes high and before any conversions start.

TERMINOLOGY

Relative Accuracy

For the AD7776, AD7777 and AD7778, relative accuracy or endpoint nonlinearity is the maximum deviation, in LSBs, of the ADC's actual code transition points from a straight line drawn between the endpoints of the ADC transfer function.

Differential Nonlinearity

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified maximum differential nonlinearity of ±1 LSB ensures no missed codes.

Bias Offset Error

For an ideal 10-bit ADC, the output code for an input voltage equal to V_{BIAS} should be midscale. The bias offset error is the difference between the actual midpoint voltage for midscale code and V_{BIAS}, expressed in LSBs.

Bias Offset Error Match

This is a measure of how closely the bias offset errors of all channels track each other. The bias offset error match of any channel must be no further away than 10 LSBs from the bias offset error of any other channel, regardless of whether the channels are independently sampled or simultaneously sampled.

Plus and Minus Full-Scale Error

The input channels of the ADC can be considered as having bipolar (positive and negative) input ranges, but which are referred to V_{BIAS} (or REFIN) instead of AGND. Positive full-scale error for the ADC is the difference between the actual input voltage required to produce the plus full-scale code transition and the ideal input voltage (V_{BIAS} + V_{SWING} −1.5 LSB), expressed in LSBs. Minus full-scale error is similarly specified for the minus full-scale code transition, relative to the ideal input voltage for this transition (V_{BIAS} − V_{SWING} + 0.5 LSB). Note that the full-scale errors for the ADC input channels are measured after their respective bias offset errors have been adjusted out.

Plus and Minus Full-Scale Error Match

This is a measure of how closely the full-scale errors of all channels track each other. The full-scale error match of any channel must be no further away than 10 LSBs from the respective full-scale error of any other channel, regardless of whether the channels are independently sampled or simultaneously sampled.

Short Circuit Current
This is defined as the maximum current which will flow either into or out of the REFOUT pin if this pin is shorted to any potential between 0 V and V_{CC}. This condition can be allowed for up to 10 seconds provided that the power dissipation of the package is not exceeded.

Signal-to-Noise and Distortion Ratio, S/(N+D)
Signal-to-noise and distortion ratio, S/(N+D), is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/(N+D) is given in decibels.

Total Harmonic Distortion, THD
Total harmonic distortion is the ratio of the rms sum of the first five harmonic components to the rms value of a full-scale input signal and is expressed in decibels. For the AD7776/AD7777/AD7778, Total harmonic distortion (THD) is defined as:

$$20\ log = \frac{(V2^2 + V3^2 + V4^2 + V5^2 + V6^2)^{1/2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and *V2*, *V3*, *V4*, *V5* and *V6* are the rms amplitudes of the individual harmonics.

Intermodulation Distortion, IMD
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa + nfb, where m, n = 0, 1, 2, 3. Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms include (fa + fb) and (fa − fb) and the third order terms include (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb).

Channel-to-Channel Isolation
Channel-to-channel isolation is a measure of the level of crosstalk between channels. It is measured by applying a full-scale 100 kHz sine wave signal to any one of the input channels and monitoring the remaining channels. The figure given is the worst case across all channels.

DIGITAL SIGNAL PROCESSING APPLICATIONS

In digital signal processing (DSP) application areas like voice recognition, echo cancellation and adaptive filtering, the dynamic characteristics S/(N+D), THD & IMD of the ADC are critical. The AD7776/AD7777/AD7778 are specified dynamically as well as with standard dc specifications. Because the track/hold amplifier has a wide bandwidth, an antialiasing filter should be placed on the analog inputs to avoid aliasing of high frequency noise back into the bands of interest.

The dynamic performance of the ADC is evaluated by applying a sine wave signal of very low distortion to a single analog input which is sampled at a 380.95 kHz sampling rate. A fast Fourier transform (FFT) plot or histogram plot is then generated from which the signal to noise and distortion, harmonic distortion and dynamic differential nonlinearity data can be obtained. Similarly, for intermodulation distortion, an input signal consisting of two pure sine waves at different frequencies is applied to the AD7776/AD7777/AD7778.

Figure 11 shows a 2048 point FFT plot for a single channel of the AD7778 with an input signal of 99.88 kHz. The SNR is 58.71 dB. It can be seen that most of the harmonics are buried in the noise floor. It should be noted that the harmonics are taken into account when calculating the S/(N+D).

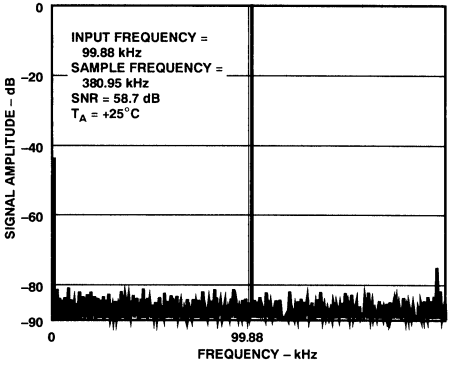

Figure 11. ADC FFT Plot

The relationship between S/(N+D) and resolution (n) is expressed by the following equation:

$$S/(N+D) = (6.02n + 1.76)\ dB$$

This is for an ideal part with no differential or integral linearity errors. These errors will cause a degradation in S/(N+D). By working backwards from the above equation, it is possible to get a measure of ADC performance expressed in effective number of bits (n).

$$n(effective) = \frac{S/(N+D)\ (dB) - 1.76}{6.02}$$

The effective number of bits plotted vs. frequency for a single channel of the AD7778 is shown in Figure 12. The effective number of bits is typically 9.5.

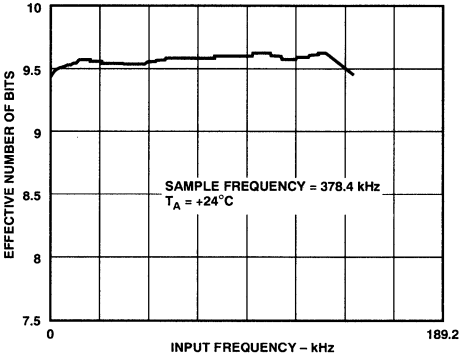

Figure 12. Effective Number of Bits vs. Frequency

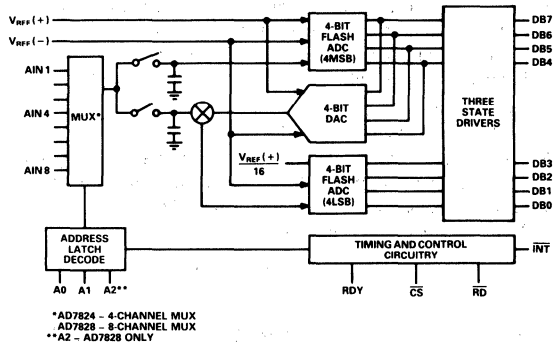
LC²MOS High Speed 4- & 8-Channel 8-Bit ADCs

AD7824/AD7828

FEATURES
4- or 8-Analog Input Channels
Built-In Track/Hold Function
10kHz Signal Handling on Each Channel
Fast Microprocessor Interface
Single +5V Supply
Low Power: 50mW
Fast Conversion Rate, 2.5μs/Channel
Tight Error Specification: 1/2LSB

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7824 and AD7828 are high-speed, multichannel, 8-bit ADCs with a choice of 4 (AD7824) or 8 (AD7828) multiplexed analog inputs. A half-flash conversion technique gives a fast conversion rate of 2.5μs per channel and the parts have a built-in track/hold function capable of digitizing full-scale signals of 10kHz (157mV/μs slew rate) on all channels. The AD7824 and AD7828 operate from a single +5V supply and have an analog input range of 0 to +5V, using an external +5V reference.

Microprocessor interfacing of the parts is simple, using standard Chip Select ($\overline{CS}$) and Read ($\overline{RD}$) signals to intitiate the conversion and read the data from the three-state data outputs. The half-flash conversion technique means that there is no need to generate a clock signal for the ADC. The AD7824 and AD7828 can be interfaced easily to most popular microprocessors.

The AD7824 and AD7828 are fabricated in an advanced, all ion-implanted, Linear-Compatible CMOS process (LC²MOS) and have low power dissipation of 40mW (typ). The AD7824 is available in a 0.3" wide, 24-pin "skinny" DIP, while the AD7828 is available in a 0.6" wide, 28-pin DIP and in 28-terminal surface mount packages.

PRODUCT HIGHLIGHTS

1. 4- or 8-channel input multiplexer gives cost-effective space-saving multichannel ADC system.
2. Fast conversion rate of 2.5μs/channel features a per channel sampling frequency of 100kHz for the AD7824 or 50kHz for the AD7828.
3. Built-in track-hold function allows handling of 4- or 8-channels up to 10kHz bandwidth (157mV/μs slew rate).
4. Tight total unadjusted error spec and channel-to-channel matching eliminate the need for user trims.
5. Single +5V supply simplifies system power requirements.
6. Fast, easy-to-use digital interface allows connection to most popular microprocessors with minimal external components. No clock signal is required for the ADC.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

SPECIFICATIONS (V_{DD} = +5V, $V_{REF}(+)$ = +5V, $V_{REF}(-)$ = GND = 0V unless otherwise noted. All specifications T_{min} to T_{max} unless otherwise noted. Specifications apply for Mode 0.)

t_{RD}	60	80	80	ns min	Read Pulse Width, Mode 1
	600	500	400	ns max	

NOTES
[1]Sample tested at 25°C to ensure compliance. All input control signals are specified with tr = tf = 20ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]C_L = 50pF.
[3]Measured with load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[4]Defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

Derates above +75°C by	6mW/°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

LC²MOS
Complete, 12-Bit Analog I/O System
AD7868

FEATURES

Complete 12-Bit I/O System, Comprising:
- **12-Bit ADC with Track/Hold Amplifier**
  - **83 kHz Throughput Rate**
  - **72 dB SNR**
- **12-Bit DAC with Output Amplifier**
  - **3 μs Settling Time**
  - **72 dB SNR**
- **On-Chip Voltage Reference**

Operates from ±5 V Supplies
Low Power – 130 mW typ
Small 0.3" Wide DIP

APPLICATIONS

Digital Signal Processing
Speech Recognition and Synthesis
Spectrum Analysis
High Speed Modems
DSP Servo Control

GENERAL DESCRIPTION

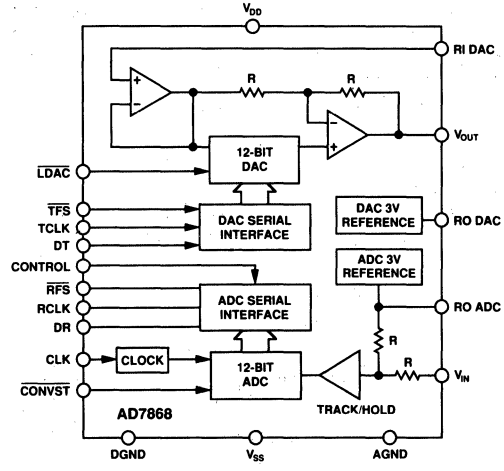
The AD7868 is a complete 12-bit I/O system containing a DAC and an ADC. The ADC is a successive approximation type with a track-and-hold amplifier having a combined throughput rate of 83 kHz. The DAC has an output buffer amplifier with a settling time of 3 μs to 12 bits. Temperature compensated 3 V buried Zener references provide precision references for the DAC and ADC.

Interfacing to both the DAC and ADC is serial, minimizing pin count and giving a small 24-pin package size. Standard control signals allow serial interfacing to most DSP machines. Asynchronous ADC conversion control and DAC updating is made possible with the $\overline{\text{CONVST}}$ and $\overline{\text{LDAC}}$ logic inputs.

The AD7868 operates from ±5 V power supplies, the analog input/output range of the ADC/DAC is ±3 V. The part is fully specified for dynamic parameters such as signal-to-noise ratio and harmonic distortion as well as traditional dc specifications.

The part is available in a 24-pin, 0.3" wide, plastic or hermetic dual-in-line package (DIP) and in a 28-pin, plastic SOIC package.

FUNCTIONAL BLOCK DIAGRAM



PRODUCT HIGHLIGHTS

1. Complete 12-Bit I/O System.
   The AD7868 contains a 12-bit ADC with a track-and-hold amplifier and a 12-bit DAC with output amplifier. Also included are separate on-chip voltage references for the DAC and the ADC.
2. Dynamic Specifications for DSP Users.
   In addition to traditional dc specifications, the AD7868 is specified for ac parameters including signal-to-noise ratio and harmonic distortion. These parameters along with important timing parameters are tested on every device.
3. Small Package.
   The AD7868 is available in a 24-pin DIP and a 28-pin SOIC package.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

SPECIFICATIONS

ADC SECTION (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ± 5%, AGND = DGND = 0 V, f_{CLK} = 2.0 MHz external. All specifications T_{min} to T_{max} unless otherwise noted.)

Parameter	A Version[1]	B Version[1]	T Version[1]	Units	Test Conditions/Comments
DYNAMIC PERFORMANCE[2]					
Signal-to-Noise Ratio[3, 4] (SNR) @ +25°C	70	72	70	dB min	V_{IN} = 10 kHz Sine Wave, f_{SAMPLE} = 83 kHz
T_{min} to T_{max}	70	71	70	dB min	Typically 71.5 dB for 0<V_{IN}<41.5 kHz
Total Harmonic Distortion (THD)	−78	−78	−76	dB max	V_{IN} = 10 kHz Sine Wave, f_{SAMPLE} = 83 kHz Typically −84 dB for 0<V_{IN}<41.5 kHz
Peak Harmonic or Spurious Noise	−78	−78	−76	dB max	V_{IN} = 10 kHz Sine Wave, f_{SAMPLE} = 83 kHz Typically −84 dB for 0<V_{IN}<41.5 kHz
Intermodulation Distortion (IMD)					
Second Order Terms	−78	−78	−76	dB max	fa = 9 kHz, fb = 9.5 kHz, f_{SAMPLE} = 50 kHz

V_{DD}	+5	+5	+5	V nom	±5% for Specified Performance
V_{SS}	−5	−5	−5	V nom	±5% for Specified Performance
I_{DD}	22	22	25	mA max	Cumulative Current from the Two V_{DD} Pins
I_{SS}	12	12	13	mA max	Cumulative Current from the Two V_{SS} Pins
Total Power Dissipation	170	170	190	mW max	Typically 130 mW

NOTES
[1]Temperature ranges are as follows: A/B Versions, −40°C to +85°C; T Version, −55°C to +125°C.
V_{IN} = ±3 V.
[3]SNR calculation includes distortion and noise components.
[4]SNR degradation due to asynchronous DAC updating during conversion is 0.1 dB typ.
[5]Measured with respect to internal reference.
[6]For capacitive loads greater than 50 pF a series resistor is required (see INTERNAL REFERENCE section).
[7]Tying the CONTROL input to V_{DD} places the device in a factory test mode where normal operation is not exhibited.
[8]Sample tested @ +25°C to ensure compliance.
Specifications subject to change without notice.

DAC SECTION (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ± 5%, AGND = DGND = 0 V, RI DAC = +3 V and decoupled as shown in Figure 2, V_{OUT} Load to AGND; R_L = 2 kΩ, C_L = 100 pF. All specifications T_{min} to T_{max} unless otherwise noted.)

Parameter	A Version[1]	B Version[1]	T Version[1]	Units	Test Conditions/Comments

t_{11}	75	100	ns min	Data Valid to TCLK Hold Time
t_{12}	40	40	ns min	$\overline{LDAC}$ Pulse Width

NOTES
[1]Timing specifications are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on DR and $\overline{RFS}$ and a 2 kΩ pull-up resistor on RCLK. The capacitance on all three outputs is 35 pF.
[3]When using internal clock, RCLK mark/space ratio (measured form a voltage level of 1.6 V) range is 40/60 to 60/40. For external clock, RCLK mark/space ratio = external clock mark/space ratio.
[4]DR will drive higher capacitance loads but this will add to t_5 since it increases the external RC time constant (4.7 kΩ//C_L) and hence the time to reach 2.4 V.
[5]Time 2 RCLK to 3 RCLK depends on conversion start to ADC clock synchronization.
[6]TCLK mark/space ratio is 40/60 to 60/40.

DSP Servo Control

GENERAL DESCRIPTION

The AD7869 is a complete 14-bit I/O system containing a DAC and an ADC. The ADC is a successive approximation type with a track-and-hold amplifier having a combined throughput rate of 83 kHz. The DAC has an output buffer amplifier with a settling time of 4 μs to 14 bits. Temperature compensated 3 V buried Zener references provide precision references for the DAC and ADC.

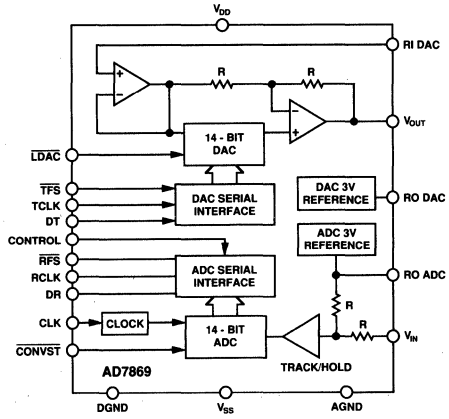
Interfacing to both the DAC and ADC is serial, minimizing pin count and giving a small 24-pin package size. Standard control signals allow serial interfacing to most DSP machines.

Asynchronous ADC conversion control and DAC updating is made possible with the $\overline{\text{CONVST}}$ and $\overline{\text{LDAC}}$ logic inputs.

The AD7869 operates form ±5 V power supplies, the analog input/output range of the ADC/DAC is ±3 V. The part is fully specified for dynamic parameters such as signal-to-noise ratio and harmonic distortion as well as traditional dc specifications.

The part is available in a 24-pin, 0.3 inch wide, plastic or hermetic dual-in-line package (DIP) and in a 28-pin, plastic SOIC package.

FUNCTIONAL BLOCK DIAGRAM



PRODUCT HIGHLIGHTS

1. Complete 14-Bit I/O System.
   The AD7869 contains a 14-bit ADC with a track-and-hold amplifier and a 14-bit DAC with output amplifier. Also included are separate on-chip voltage references for the DAC and the ADC.
2. Dynamic Specifications for DSP Users.
   In addition to traditional dc specifications, the AD7869 is specified for ac parameters including signal-to-noise ratio and harmonic distortion. These parameters along with important timing parameters are tested on every device.
3. Small Package.
   The AD7869 is available in a 24-pin DIP and a 28-pin SOIC package.

Total Power Dissipation	170	170	mW max	Typically 130 mW

NOTES
[1]Temperature ranges are as follows: J Version, 0°C to +70°C; A Version, −40°C to +85°C.
[2]V_{IN} = ±3 V.
[3]SNR calculation includes distortion and noise components.
[4]SNR degradation due to asynchronous DAC updating during conversion is 0.1 dB typ.
[5]Measured with respect to internal reference.
[6]For capacitive loads greater than 50 pF a series resistor is required (see Internal Reference section).
[7]Tying the CONTROL input to V_{DD} places the device in a factory test mode where normal operation is not exhibited.
[8]Sample tested @ +25°C to ensure compliance.

Specifications subject to change without notice.

DAC SECTION (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ± 5%, AGND = DGND = 0 V, RI DAC = +3 V and decoupled as shown in Figure 2, V_{OUT} Load to AGND; = 2 kΩ, C_L = 100 pF. All specifications T_{min} to T_{max} unless otherwise noted.)

POWER REQUIREMENTS	As per ADC Section			

NOTES
[1]Temperature ranges are as follows: J Version, 0°C to +70°C; A Version, −40°C to +85°C.
[2]V_{OUT} (p-p) = ±3 V.
[3]SNR calculation includes distortion and noise components.
[4]Using external sample and hold, see Figures 13 to 15.
[5]Measured with respect to REF IN and includes bipolar offset error.
[6]For capacitive loads greater than 50 pF a series resistor is required (see Internal Reference section).
[7]Sample tested @ +25°C to ensure compliance.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1, 2] (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ±5%, AGND = DGND = 0 V)

Parameter	Limit at T_{min}, T_{max} (All Versions)	Units	Conditions/Comments
ADC TIMING			
t_1	50	ns min	$\overline{CONVST}$ Pulse Width
t_2[3]	440	ns min	RCLK Cycle Time, Internal Clock
t_3	100	ns min	$\overline{RFS}$ to RCLK Falling Edge Setup Time
t_4	20	ns min	RCLK Rising Edge to $\overline{RFS}$
	100	ns max	
t_5[4]	155	ns max	RCLK to Valid Data Delay, C_L = 35 pF
t_6	4	ns min	Bus Relinquish Time after RCLK
	100	ns max	
t_{13}[5]	2 RCLK +200 to 3 RCLK + 200	ns typ	$\overline{CONVST}$ to $\overline{RFS}$ Delay
DAC TIMING			
t_7	50	ns min	$\overline{TFS}$ to TCLK Falling Edge
t_8	75	ns min	TCLK Falling Edge to $\overline{TFS}$
t_9[6]	150	ns min	TCLK Cycle Time
t_{10}	30	ns min	Data Valid to TCLK Setup Time
t_{11}	75	ns min	Data Valid to TCLK Hold Time
t_{12}	40	ns min	$\overline{LDAC}$ Pulse Width

NOTES
[1]Timing specifications are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on DR and $\overline{RFS}$ and a 2 kΩ pull-up resistor on RCLK. The capacitance on all three outputs is 35 pF.
[3]When using internal clock, RCLK mark/space ratio (measured form a voltage level of 1.6 V) range is 40/60 to 60/40. For external clock, RCLK mark/space ratio = external clock mark/space ratio.
[4]DR will drive higher capacitance loads but this will add to t_5 since it increases the external RC time constant (4.7 kΩ//C_L) and hence the time to reach 2.4 V.
[5]Time 2 RCLK to 3 RCLK depends on conversion start to ADC clock synchronization.
[6]TCLK mark/space ratio is 40/60 to 60/40.

Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 secs) . . . . . +300°C
Power Dissipation (Any Package) to +75°C . . . . . 1000 mW
Derates above +75°C by . . . . . 10 mW/°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model	Temperature Range	Signal-to-Noise Ratio (SNR)	Relative Accuracy	Package Option*
AD7869JN	0°C to +70°C	78 dB	±2 LSB max	N-24

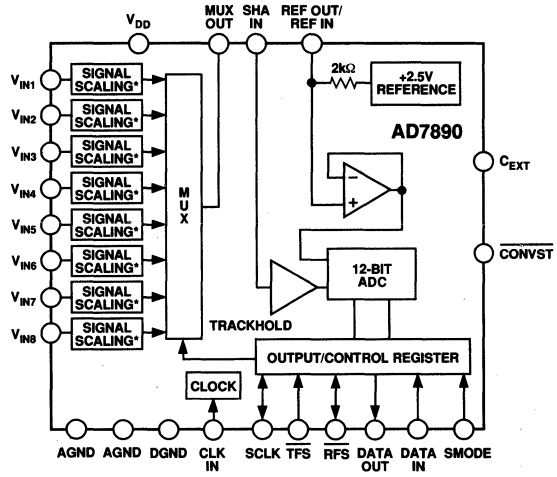
LC²MOS 8-Channel, 12-Bit Serial, Data Acquisition System

AD7890

FEATURES

Fast 12-Bit ADC with 5.9 μs Conversion Time
Eight Single-Ended Analog Input Channels
Selection of Input Ranges
±10 V for AD7890-10
0 V to +4.096 V for AD7890-4
0 V to +2.5 V for AD7890-2
Allows Separate Access to Multiplexer and ADC
On-Chip Track/Hold Amplifier
On-Chip Reference
High Speed, Flexible, Serial Interface
Single Supply, Low Power Operation (50 mW max)
Power-Down Mode (75 μW typ)

FUNCTIONAL BLOCK DIAGRAM



*NO SCALING ON AD7890-2

GENERAL DESCRIPTION

The AD7890 is an eight-channel 12-bit data acquisition system. The part contains an input multiplexer, an on-chip track/hold amplifier, a high-speed 12-bit ADC, a +2.5 V reference and a high speed, serial interface. The part operates from a single +5 V supply and accepts an analog input range of ±10 V (AD7890-10), 0 to +4.096 V (AD7890-4) and 0 to +2.5 V (AD7890-2).

The multiplexer on the part is independently accessible. This allows the user to insert an antialiasing filter or signal conditioning, if required, between the multiplexer and the ADC. This means that one antialiasing filter can be used for all eight channels. Connection of an external capacitor allows the user to adjust the time given to the multiplexer settling to include any external delays in the filter or signal conditioning circuitry.

Output data from the AD7890 is provided via a high speed bidirectional serial interface port. The part contains an on-chip control register, allowing control of channel selection, conversion start and power-down via the serial port. Versatile, high speed logic ensures easy interfacing to serial ports on microcontrollers and digital signal processors.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the AD7890 is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

Power dissipation in normal mode is low at 30 mW typ and the part can be placed in a standby (power-down) mode if it is not required to perform conversions. The AD7890 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin, 0.3" wide, plastic or hermetic dual-in-line package or in a 24-pin small outline package (SOIC).

PRODUCT HIGHLIGHTS

1. Complete 12-Bit Data Acquisition System on a Chip
   The AD7890 is a complete monolithic ADC combining an eight-channel multiplexer, 12-bit ADC, +2.5 V reference and a track/hold amplifier on a single chip.
2. Separate Access to Multiplexer and ADC
   The AD7890 provides access to the output of the multiplexer allowing one antialiasing filter for eight channels—a considerable saving over the eight antialiasing filters required if the multiplexer was internally connected to the ADC.
3. High Speed Serial Interface
   The part provides a high speed serial interface for easy connection to serial ports of microcontrollers and DSP processors.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

SPECIFICATIONS (V_{DD} = +5 V, AGND = DGND = 0 V, REF IN = +2.5 V, $f_{CLK\ IN}$ = 2.5 MHz external, MUX OUT connect to SHA IN. All specifications T_{MIN} to T_{MAX} unless otherwise noted.)

NOTES
[1]Temperature ranges are as follows: A, B Versions: −40°C to +85°C; S Version: −55°C to +125°C.
[2]See Terminology.
[3]This sample rate is only achievable when using the part in external clocking mode.
[4]Full-scale error match applies to positive full scale for the AD7890-2 and AD7890-4. It applies to both positive and negative full scale for the AD7890-10.
[5]Sample tested @ +25°C to ensure compliance.
[6]Analog inputs on AD7890-10 must be at 0 V to achieve correct power-down current.
Specifications subject to change without notice.

*N = Plastic DIP; Q = Cerdip; R = SOIC. For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7890 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

TIMING CHARACTERISTICS[1, 2] (V_{DD} = +5 V ± 5%, AGND = DGND = 0 V, REF IN = +2.5 V, $f_{CLK\ IN}$ = 2.5 MHz external, MUX OUT connected to SHA IN.)

Parameter	Limit at T_{MIN}, T_{MAX} (A, B, S Versions)	Units	Conditions/Comments
f_{CLKIN}[3]	100	kHz min	Master Clock Frequency. For Specified Performance
	2.5	MHz max	
$t_{CLK\ IN\ LO}$	0.3 × $t_{CLK\ IN}$	ns min	Master Clock Input Low Time
$t_{CLK\ IN\ HI}$	0.3 × $t_{CLK\ IN}$	ns min	Master Clock Input High Time
tr[4]	25	ns max	Digital Output Rise Time. Typically 10 ns
tf[4]	25	ns max	Digital Output Fall Time. Typically 10 ns
$t_{CONVERT}$	5.9	μs max	Conversion Time
t_{CST}	100	ns min	$\overline{CONVST}$ Pulse Width
Self-Clocking Mode			
t_1	$t_{CLK\ IN\ HI}$ +50	ns max	$\overline{RFS}$ Low to SCLK Falling Edge
t_2[5]	25	ns max	$\overline{RFS}$ Low to Data Valid Delay
t_3	$t_{CLK\ IN\ HI}$	ns nom	SCLK High Pulse Width
t_4	$t_{CLK\ IN\ LO}$	ns nom	SCLK Low Pulse Width
t_5[5]	20	ns max	SCLK Rising Edge to Data Valid Delay
t_6	40	ns max	SCLK Rising Edge to $\overline{RFS}$ Delay
t_7[6]	50	ns max	Bus Relinquish Time after Rising Edge of SCLK
t_8	0	ns min	$\overline{TFS}$ Low to SCLK Falling Edge
	$t_{CLK\ IN}$ + 50	ns max	
t_9	0	ns min	Data Valid to $\overline{TFS}$ Falling Edge Setup Time (A2 Address Bit)
t_{10}	20	ns min	Data Valid to SCLK Falling Edge Setup Time
t_{11}	10	ns min	Data Valid to SCLK Falling Edge Hold Time
t_{12}	20	ns min	$\overline{TFS}$ to SCLK Falling Edge Hold Time
External-Clocking Mode			
t_{13}	20	ns min	$\overline{RFS}$ Low to SCLK Falling Edge Setup Time
t_{14}[5]	40	ns max	$\overline{RFS}$ Low to Data Valid Delay
t_{15}	50	ns min	SCLK High Pulse Width
t_{16}	50	ns min	SCLK Low Pulse Width
t_{17}[5]	35	ns max	SCLK Rising Edge to Data Valid Delay
t_{18}	20	ns min	$\overline{RFS}$ to SCLK Falling Edge Hold Time
t_{19}[6]	50	ns max	Bus Relinquish Time after Rising Edge of $\overline{RFS}$
t_{19A}[6]	90	ns max	Bus Relinquish Time after Rising Edge of SCLK
t_{20}	20	ns min	$\overline{TFS}$ Low to SCLK Falling Edge Setup Time
t_{21}	10	ns min	Data Valid to SCLK Falling Edge Setup Time
t_{22}	15	ns min	Data Valid to SCLK Falling Edge Hold Time
t_{23}	40	ns min	$\overline{TFS}$ to SCLK Falling Edge Hold Time

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]See Figures 8 to 11.
[3]The AD7890 is production tested with f_{CLKIN} at 2.5 MHz. It is guaranteed by characterization to operate at 100 kHz.
[4]Specified using 10% and 90% points on waveform of interest.
[5]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross 0.8 V or 2.4 V.
[6]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 50 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.

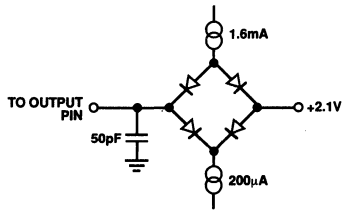

Figure 1. Load Circuit for Access Time and Bus Relinquish Time

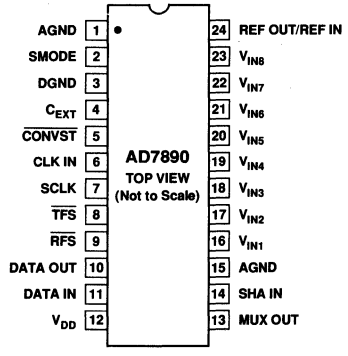
PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
2	SMODE	Control Input. Determines whether the part operates in its External Clocking (slave) or Self-Clocking (master) serial mode. With SMODE at a logic low, the part is in its Self-Clocking serial mode with $\overline{RFS}$ and SCLK as outputs. This Self-Clocking mode is useful for connection to shift registers or to serial ports of DSP processors. With SMODE at a logic high, the part is in its External Clocking serial mode with SCLK and $\overline{RFS}$ as inputs. This External Clocking mode is useful for connection to the serial port of microcontrollers such as the 8XC51 and the 68HCXX and for connection to the serial ports of DSP processors.
3	DGND	Digital Ground. Ground reference for digital circuitry.
4	C_{EXT}	External Capacitor. An external capacitor is connected to this pin to determine the length of the internal pulse (see $\overline{CONVST}$ input and Control Register section). Larger capacitances on this pin extend the pulse to allow for settling time delays through an external antialiasing filter or signal conditioning circuitry.
5	$\overline{CONVST}$	Convert Start. Edge-triggered logic input. A low to high transition on this input puts the track/hold into hold and initiates conversion provided that the internal pulse has timed out (see Control Register section). If the internal pulse is active when the $\overline{CONVST}$ goes high, the track/hold will not go into hold until the pulse times out. If the internal pulse has timed out when $\overline{CONVST}$ goes high, the rising edge of $\overline{CONVST}$ drives the track/hold into hold and initiates conversion.
6	CLK IN	Clock Input. An external TTL-compatible clock is applied to this input pin to provide the clock source for the conversion sequence. In the Self-Clocking serial mode, the SCLK output is derived from this CLK IN pin.
7	SCLK	Serial Clock Input. In the External Clocking (slave) mode (see Serial Interface section) this is an externally applied serial clock which is used to load serial data to the control register and to access data from the output register. In the Self-Clocking (master) mode, the internal serial clock, which is derived from the clock input (CLK IN), appears on this pin. Once again, it is used to load serial data to the control register and to access data from the output register.
8	$\overline{TFS}$	Transmit Frame Synchronization Pulse. Active low logic input with serial data expected after the falling edge of this signal.
9	$\overline{RFS}$	Receive Frame Synchronization Pulse. In the External Clocking mode, this pin is an active low logic input with $\overline{RFS}$ provided externally as a strobe or framing pulse to access serial data from the output register. In the Self-Clocking mode, it is an active low output which is internally generated and provides a strobe or framing pulse for serial data from the output register. For applications which require that data be transmitted and received at the same time, $\overline{RFS}$ and $\overline{TFS}$ should be connected together.
10	DATA OUT	Serial Data Output. Sixteen bits of serial data are provided with one leading zero, preceding the three address bits of the Control register and the 12 bits of conversion data. Serial data is valid on the falling edge of SCLK for sixteen edges after $\overline{RFS}$ goes low. Output coding from the ADC is 2s complement for the AD7890-10 and straight binary for the AD7890-4 and AD7890-2.
11	DATA IN	Serial Data Input. Serial data to be loaded to the control register is provided at this input. The first five bits of serial data are loaded to the control register on the first five falling edges of SCLK after $\overline{TFS}$ goes low. Serial data on subsequent SCLK edges is ignored while $\overline{TFS}$ remains low.
12	V_{DD}	Positive supply voltage, +5 V ± 5%.
13	MUX OUT	Multiplexer Output. The output of the multiplexer appears at this pin. The output voltage range from this output is 0 V to +2.5 V for the nominal analog input range to the selected channel. The output impedance of this output is nominally 3.5 kΩ. If no external antialiasing filter is required, MUX OUT should be connected to SHA IN.
14	SHA IN	Track/Hold Input. The input to the on-chip track/hold is applied to this pin. It is a high impedance input and the input voltage range is 0 V to +2.5 V.
15	AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
16	V_{IN1}	Analog Input Channel 1. Single-ended analog input. The analog input range on is ±10 V (AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.

Pin	Mnemonic	Description
17	V_{IN2}	Analog Input Channel 2. Single-ended analog input. The analog input range on is ±10 V (AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
18	V_{IN3}	Analog Input Channel 3. Single-ended analog input. The analog input range on is ±10 V(AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
19	V_{IN4}	Analog Input Channel 4. Single-ended analog input. The analog input range on is ±10 V(AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
20	V_{IN5}	Analog Input Channel 5. Single-ended analog input. The analog input range on is ±10 V(AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
21	V_{IN6}	Analog Input Channel 6. Single-ended analog input. The analog input range on is ±10 V(AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
22	V_{IN7}	Analog Input Channel 7. Single-ended analog input. The analog input range on is ±10 V(AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
23	V_{IN8}	Analog Input Channel 8. Single-ended analog input. The analog input range on is ±10 V(AD7890-10), 0 V to +4.096 V (AD7890-4) and 0 V to +2.5 V (AD7890-2). The channel to be converted is selected using the A0, A1 and A2 bits in the control register. The multiplexer has guaranteed break-before-make operation.
24	REF OUT/REF IN	Voltage Reference Output/Input. The part can be used with either its own internal reference or with an external reference source. The on-chip +2.5 V reference voltage is provided at this pin. When using this internal reference as the reference source for the part, REF OUT should decoupled to AGND with a 0.1 μF disc ceramic capacitor. The output impedance of this reference source is typically 2 kΩ. When using an external reference source as the reference voltage for the part, the reference source should be connected to this pin. This overdrives the internal reference and provides the reference source for the part. The REF IN input is buffered on-chip. The nominal reference voltage for correct operation of the AD7890 is +2.5 V.

PIN CONFIGURATION

DIP and SOIC



TERMINOLOGY

Signal to (Noise + Distortion) Ratio
This is the measured ratio of signal to (noise + distortion) at the output of the A/D converter. The signal is the rms amplitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio is dependent upon the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to (noise + distortion) ratio for an ideal N-bit converter with a sine wave input is given by:

$$\textit{Signal to (Noise + Distortion)} = (6.02N + 1.76)\ dB$$

Thus for a 12-bit converter, this is 74 dB.

Total Harmonic Distortion
Total harmonic distortion (THD) is the ratio of the rms sum of harmonics to the fundamental. For the AD7890, it is defined as:

$$THD\ (dB) = 20\ log\ \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonics.

Peak Harmonic or Spurious Noise
Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor, it will be a noise peak.

Intermodulation Distortion
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa ± nfb where m, n = 0, 1, 2, 3, etc. Intermodulation terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa + fb) and (fa − fb), while the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb).

The AD7890 is tested using the CCIF standard where two input frequencies near the top end of the input bandwidth are used. In this case, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs.

Channel-to-Channel Isolation
Channel-to-channel isolation is a measure of the level of crosstalk between channels. It is measured by applying a full-scale 1 kHz signal to any one of the other seven inputs and determining how much that signal is attenuated in the channel of interest. The figure given is the worst case across all eight channels.

Relative Accuracy
Relative accuracy or endpoint nonlinearity is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function.

Differential Nonlinearity
This is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Positive Full-Scale Error (AD7890-10)
This is the deviation of the last code transition (01 . . . 110 to 01 . . . 111) from the ideal (4 × REF IN − 1 LSB) after the Bipolar Zero Error has been adjusted out.

Positive Full-Scale Error (AD7890-4)
This is the deviation of the last code transition (11 . . . 110 to 11 . . . 111) from the ideal (1.638 × REF IN − 1 LSB) after the Unipolar Offset Error has been adjusted out.

Positive Full-Scale Error (AD7890-2)
This is the deviation of the last code transition (11 . . . 110 to 11 . . . 111) from the ideal (REF IN − 1 LSB) after the Unipolar Offset Error has been adjusted out.

Bipolar Zero Error (AD7890-10)
This is the deviation of the midscale transition (all 0s to all 1s) from the ideal 0 V (AGND).

Unipolar Offset Error (AD7890-2, AD7890-4)
This is the deviation of the first code transition (00 . . . 000 to 00 . . . 001) from the ideal 0 V (AGND).

Negative Full-Scale Error (AD7890-10)
This is the deviation of the first code transition (10 . . . 000 to 10 . . . 001) from the ideal (−4 × REF IN + 1 LSB) after Bipolar Zero Error has been adjusted out.

Track/Hold Acquisition Time
Track/Hold acquisition time is the time required for the output of the track/hold amplifier to reach its final value, within ±1/2 LSB, after the end of conversion (the point at which the track/hold returns to track mode). It also applies to situations where a change in the selected input channel takes place or where there is a step input change on the input voltage applied to the selected V_{IN} input of the AD7890. It means that the user must wait for the duration of the track/hold acquisition time after the end of conversion or after a channel change/step input change to V_{IN} before starting another conversion, to ensure that the part operates to specification.

CONTROL REGISTER

The Control Register for the AD7890 contains 5 bits of information as described below. Six serial clock pulses must be provided to the part in order to write data to the Control Register (seven if the write is required to put the part in Standby Mode). If $\overline{TFS}$ returns high before six serial clock cycles then no data transfer takes place to the Control Register and the write cycle will have to be restarted to write the data to the Control Register. If, however, the CONV bit of the register (see below) is set to a Logic 1, then a conversion will be initiated whenever a Control Register write takes place regardless of how many serial clock cycles the $\overline{TFS}$ remains low for. The default (power-on) condition of all bits in the Control Register is 0.

MSB

A2	A1	A0	CONV	STBY

A2	Address Input. This input is the most significant address input for multiplexer channel selection.
A1	Address Input. This is the 2nd most significant address input for multiplexer channel selection.
A0	Address Input. Least significant address input for multiplexer channel selection. When the address is written to the control register, an internal pulse is initiated, the pulse width of which is determined by the value of capacitance on the C_{EXT} pin. When this pulse is active, it ensures the conversion process cannot be activated. This allows for the multiplexer settling time and track/hold acquisition time before the track/hold goes into hold and conversion is initiated. In applications where there is an antialiasing filter between MUX OUT and SHA IN, the filter settling time can be taken into account before the input at SHA IN is sampled. When the internal pulse times out, the track/hold goes into hold and conversion is initiated.
CONV	Conversion Start. Writing a 1 to this bit initiates a conversion in a similar manner to the $\overline{CONVST}$ input. Continuous conversion starts do not take place when there is a 1 in this location. The internal pulse and the conversion process are initiated after the sixth serial clock cycle of the write operation if a 1 is written to this bit. With a 1 in this bit, the hardware conversion start i.e., the $\overline{CONVST}$ input, is disabled. Writing a 0 to this bit enables the hardware $\overline{CONVST}$ input.
STBY	Standby Mode Input. Writing a 1 to this bit places the device in its standby or power-down mode. Writing a 0 to this bit places the device in its normal operating mode. The part does not enter its standby mode until the seventh falling edge of SCLK in a write operation. Therefore, the part requires seven serial clock pulses in its serial write operation if it is required to put the part into standby

CONVERTER DETAILS

The AD7890 is an eight-channel, 12-bit, single supply, serial data acquisition system. It provides the user with signal scaling, multiplexer, track/hold, reference, A/D converter and versatile serial logic functions on a single chip. The signal scaling allows the part to handle ±10 V input signals (AD7890-10) and 0 V to +4.096 V input signals (AD7890-4) while operating from a single +5 V supply. The AD7890-2 contains no signal scaling and accepts an analog input range of 0 V to +2.5 V. The part operates from a +2.5 V reference which can be provided from the part's own internal reference or from an external reference source.

Unlike other single chip data acquisition solutions, the AD7890 provides the user with separate access to the multiplexer and the A/D converter. This means that the flexibility of separate multiplexer and ADC solutions is not sacrificed with the one-chip solution. With access to the multiplexer output, the user can implement external signal conditioning between the multiplexer and the track/hold. It means that one antialiasing filter can be used on the output of the multiplexer to provide the antialiasing function for all eight channels.

Conversion is initiated on the AD7890 either by pulsing the $\overline{CONVST}$ input or by writing a Logic 1 to the CONV bit of the Control Register. When using the hardware $\overline{CONVST}$ input, on the rising edge of the $\overline{CONVST}$ signal, the on-chip track/hold goes from track to hold mode and the conversion sequence is started provided the internal pulse has timed out. This internal pulse (which appears at the C_{EXT} pin) is initiated whenever the multiplexer address is loaded to the AD7890 Control Register. This pulse goes from high to low when a serial write to the part is initiated. It starts to discharge on the sixth falling clock edge of SCLK in a serial write operation to the part. The track/hold cannot go into hold and conversion cannot be initiated until the C_{EXT} pin has crossed its trigger point of 2.5 V. The discharge time of the voltage on C_{EXT} depends upon the value of capacitor connected to the C_{EXT} pin (see C_{EXT} Functioning section). The fact that the pulse is initiated every time a write to the control register takes place means that the software conversion start and track/hold signal is always delayed by the internal pulse.

The conversion clock for the part is generated from the clock signal applied to the CLK IN pin of the part. Conversion time for the AD7890 is 5.9 μs from the rising edge of the hardware $\overline{CONVST}$ signal and the track/hold acquisition time is 2 μs. To obtain optimum performance from the part, the data read operation or Control Register write operation should not occur during the conversion or during 500 ns prior to the next conversion. This allows the part to operate at throughput rates up to 117 kHz in the external clocking mode and achieve data sheet specifications. The part can operate at slightly higher throughput rates (up to 127 kHz), again in external clocking mode with degraded performance (see Timing and Control section). The throughput rate for self clocking mode is limited by the serial clock rate to 78 kHz.

All unused inputs should be connected to a voltage within the nominal analog input range to avoid noise pickup. On the AD7890-10, if any one of the input channels which are not being converted goes more negative than −12 V, it can interfere with the conversion on the selected channel.

CIRCUIT DESCRIPTION

Analog Input Section

The AD7890 is offered as three part types, the AD7890-10 which handles a ±10 V input voltage range, the AD7890-4 which handles a 0 to +4.096 V input range and the AD7890-2 which handles a 0 to +2.5 V input voltage range.

AD7890-10

Figure 2 shows the analog input section for the AD7890-10. The analog input range for each of the analog inputs is ±10 V into an input resistance of typically 33 kΩ. This input is benign with no dynamic charging currents with the resistor attenuator stage followed by the multiplexer and in cases where MUX OUT is connected to SHA IN this is followed by the high input impedance stage of the track/hold amplifier. The designed code transitions occur on successive integer LSB values (i.e., 1 LSB, 2 LSBs, 3 LSBs . . .). Output coding is 2s complement binary with 1 LSB = FS/4096 = 20 V/4096 = 4.88 mV. The ideal input/output transfer function is shown in Table I.

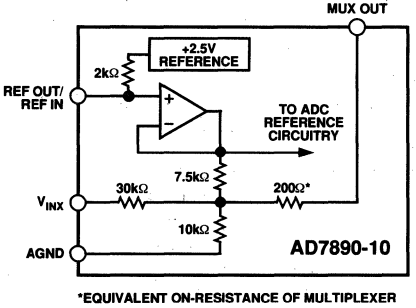


Figure 2. AD7890-10 Analog Input Structure

Table I. Ideal Input/Output Code Table for the AD7890-10

Analog Input[1]	Digital Output Code Transition
+FSR/2 − 1 LSB[2] (9.995117 V)	011 . . . 110 to 011 . . . 111
+FSR/2 − 2 LSBs (9.990234 V)	011 . . . 101 to 011 . . . 110
+FSR/2 − 3 LSBs (9.985352 V)	011 . . . 100 to 011 . . . 101
AGND + 1 LSB (0.004883 V)	000 . . . 000 to 000 . . . 001
AGND (0.000000 V)	111 . . . 111 to 000 . . . 000
AGND − 1 LSB (−0.004883 V)	111 . . . 110 to 111 . . . 111
−FSR/2 + 3 LSBs (−9.985352 V)	100 . . . 010 to 100 . . . 011
−FSR/2 + 2 LSBs (−9.990234 V)	100 . . . 001 to 100 . . . 010
−FSR/2 + 1 LSB (−9.995117 V)	100 . . . 000 to 100 . . . 001

NOTES
[1]FSR is full-scale range and is 20 V with REF IN = +2.5 V.
[2]1 LSB = FSR/4096 = 4.883 mV with REF IN = +2.5 V.

AD7890-4

Figure 3 shows the analog input section for the AD7890-4. The analog input range for each of the analog inputs is ±10 V into an input resistance of typically 15 kΩ. This input is benign with no dynamic charging currents with the resistor attenuator stage followed by the multiplexer and in cases where MUX OUT is connected to SHA IN this is followed by the high input impedance stage of the track/hold amplifier. The designed code transitions occur on successive integer LSB values (i.e., 1 LSB, 2 LSBs, 3 LSBs . . .). Output coding is straight (natural) binary with 1 LSB = FS/4096 = 4.096 V/4096 = 1 mV. The ideal input/output transfer function is shown in Table II.

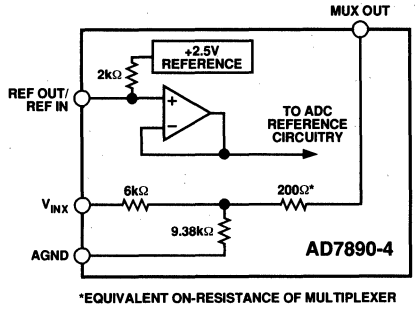

Figure 3. AD7890-4 Analog Input Structure

Table II. Ideal Input/Output Code Table for the AD7890-4

Analog Input[1]	Digital Output Code Transition
+FSR − 1 LSB[2] (4.095 V)	111 . . . 110 to 111 . . . 111
+FSR − 2 LSBs (4.094 V)	111 . . . 101 to 111 . . . 110
+FSR − 3 LSBs (4.093 V)	111 . . . 100 to 111 . . . 101
AGND + 3 LSBs (0.003 V)	000 . . . 010 to 000 . . . 011
AGND + 2 LSBs (0.002 V)	000 . . . 001 to 000 . . . 010
AGND + 1 LSB (0.001 V)	000 . . . 000 to 000 . . . 001

NOTES
[1]FSR is full-scale range and is 4.096 V with REF IN = +2.5 V.
[2]1 LSB = FSR/4096 = 1 mV with REF IN = +2.5 V.

AD7890-2

The analog input section for the AD7890-2 contains no biasing resistors and the selected analog input connects to the multiplexer and in cases where MUX OUT is connected to SHA IN this is followed by the high input impedance stage of the track/hold amplifier. The analog input range is, therefore, 0 V to +2.5 V into a high impedance stage with an input current of less than 50 nA. The designed code transitions occur on successive integer LSB values (i.e., 1 LSB, 2 LSBs, 3 LSBs . . . FS-1 LSBs). Output coding is straight (natural) binary with 1 LSB = FS/4096 = 2.5 V/4096 = 0.61 mV. The ideal input/output transfer function is shown in Table III.

Table III. Ideal Input/Output Code Table for the AD7890-2

Analog Input[1]	Digital Output Code Transition
+FSR − 1 LSB[2] (2.499390 V)	111 . . . 110 to 111 . . . 111
+FSR − 2 LSBs (2.498779 V)	111 . . . 101 to 111 . . . 110
+FSR − 3 LSBs (2.498169 V)	111 . . . 100 to 111 . . . 101
AGND + 3 LSBs (0.001831 V)	000 . . . 010 to 010 . . . 011
AGND + 2 LSBs (0.001221 V)	000 . . . 001 to 001 . . . 010

NOTES
[1]FSR is full-scale range and is 2.5 V with REF IN = +2.5 V.
[2]1 LSB = FSR/4096 = 0.61 mV with REF IN = +2.5 V.

Track/Hold Section

The SHA IN input on the AD7890 connects directly to the input stage of the track/hold amplifier. This is a high impedance input with input leakage currents of less than 50 nA. Connecting the MUX OUT pin directly to the SHA IN pin connects the multiplexer output directly to the track/hold amplifier. The input voltage range for this input is 0 to +2.5 V. If external circuitry is connected between MUX OUT and SHA IN, then the user must ensure that the input voltage range to the SHA IN input is 0 to +2.5 V to ensure that the full dynamic range of the converter is utilized.

The track/hold amplifier on the AD7890 allows the ADC to accurately convert an input sine wave of full-scale amplitude to 12-bit accuracy. The input bandwidth of the track/hold is greater than the Nyquist rate of the ADC even when the ADC is operated at its maximum throughput rate of 117 kHz (i.e., the track/hold can handle input frequencies in excess of 58 kHz).

The track/hold amplifier acquires an input signal to 12-bit accuracy in less than 2 μs. The operation of the track/hold is essentially transparent to the user. The track/hold amplifier goes from its tracking mode to its hold mode at the start of conversion. The start of conversion is the rising edge of $\overline{\text{CONVST}}$ (assuming the internal pulse has timed out) for hardware conversion starts and for software conversion starts is the point where the internal pulse is timed out. The aperture time for the track/hold (i.e., the delay time between the external $\overline{\text{CONVST}}$ signal and the track/hold actually going into hold) is typically 15 ns. For software conversion starts, the time depends on the internal pulse widths. Therefore, for software conversion starts, the sampling instant is not very well defined. For sampling systems which require well defined, equidistant sampling, it may not be possible to achieve optimum performance from the part using the software conversion start. At the end of conversion, the part returns to its tracking mode. The acquisition time of the track/hold amplifier begins at this point.

Reference Section

The AD7890 contains a single reference pin, labelled REF OUT/REF IN, which either provides access to the part's own +2.5 V reference or to which an external +2.5 V reference can be connected to provide the reference source for the part. The part is specified with a +2.5 V reference voltage. Errors in the reference source will result in gain errors in the AD7890's transfer function and will add to the specified full-scale errors on the part. On the AD7893-10, it will also result in an offset error injected in the attenuator stage.

The AD7890 contains an on-chip +2.5 V reference. To use this reference as the reference source for the AD7890, simply connect a 0.1 μF disc ceramic capacitor from the REF OUT/REF IN pin to AGND. The voltage which appears at this pin is internally buffered before being applied to the ADC. If this reference is required for use external to the AD7890, it should be buffered as the source impedance of this output is 2 kΩ nominal. The tolerance on the internal reference is ±10 mV at 25°C with a typical temperature coefficient of 25 ppm/°C and a maximum error over temperature of ±25 mV.

If the application requires a reference with a tighter tolerance or the AD7890 needs to be used with a system reference, then the user has the option of connecting an external reference to this REF OUT/REF IN pin. The external reference will effectively overdrive the internal reference and thus provide the reference source for the ADC. The reference input is buffered but has a nominal 2 kΩ resistor connected to the AD7890's internal reference. Suitable reference sources for the AD7890 include the AD680, AD780 and REF-43 precision +2.5 V references.

Timing and Control Section

The AD7890 is capable of two interface modes, selected by the SMODE input. The first of these is a self-clocking mode where the part provides the frame sync, serial clock and serial data at the end of conversion. In this mode the serial clock rate is determined by the master clock rate of the part (at CLK IN input). The second mode is an external clocking mode where the user provides the frame sync and serial clock signals to obtain the serial data from the part. In this second mode, the user has control of the serial clock rate up to a maximum of 10 MHz. The two modes are discussed in more detail in the Serial Interface section.

The part also provides hardware and software conversion start features. The former provides a well-defined sampling instant with the track/hold going into hold on the rising edge of the $\overline{\text{CONVST}}$ signal. For the software conversion start, a write to the CONV bit to the Control Register initiates the conversion sequence. However, for the software conversion start an internal pulse has to time out before the input signal is sampled. This pulse, plus the difficult in maintaining exactly equal delays between each software conversion start command, means that the dynamic performance of the AD7890 may have difficulty meeting spec when used in software conversion start mode.

The AD7890 provides separate channel select and conversion start control. This allows the user to optimize the throughput rate of the system. Once the track/hold has gone into hold mode, the input channel can be updated and the input voltage can settle to the new value while the present conversion is in progress.

Assuming the internal pulse has timed out before the $\overline{\text{CONVST}}$ pulse is exercised, the conversion will consist of 14.5 master clock cycles. In the self-clocking mode, the conversion time is defined as the time from the rising edge of $\overline{\text{CONVST}}$ to the falling edge of $\overline{\text{RFS}}$ (i.e., when the device starts to transmit its conversion result). This time includes the 14.5 master clock cycles plus the updating of the output register and delay time in outputting the $\overline{\text{RFS}}$ signal, resulting in a total conversion time of 5.9 μs maximum. Figure 4 shows the conversion timing for the AD7890 when used in the Self-Clocking (Master) Mode with hardware $\overline{\text{CONVST}}$. The timing diagram assumes that the internal pulse is not active when the $\overline{\text{CONVST}}$ signal goes high. To ensure this, the channel address to be converted should be selected by writing to the Control Register prior to the $\overline{\text{CONVST}}$ pulse. Sufficient setup time should be allowed between the Control Register write and the $\overline{\text{CONVST}}$ to ensure that the internal pulse has timed out. The duration of the internal pulse (and hence the duration of setup time) depends on the value of C_{EXT}.

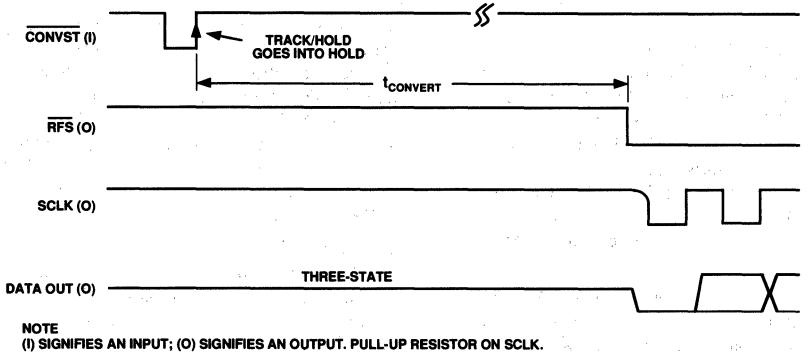

Figure 4. Self-Clocking (Master) Mode Conversion Sequence

When using the device in the External-Clocking Mode, the output register can be read at any time and the most up-to-date conversion result will be obtained. However, reading data from the output register or writing data to the Control Register during conversion or during the 500 ns prior to the next $\overline{\text{CONVST}}$ will result in reduced performance from the part. A read operation to the output register has most effect on performance with the signal-to-noise ratio likely to degrade especially when higher serial clock rates are used while the code flicker from the part will also increase (see AD7890 Performance section).

Figure 5 shows the timing and control sequence required to obtain optimum performance from the part in the external clocking mode. In the sequence shown, conversion is initiated on the rising edge of $\overline{\text{CONVST}}$ and new data is available in the output register of the AD7890 5.9 μs later. Once the read operation has taken place, a further 500 ns should be allowed before the next rising edge of $\overline{\text{CONVST}}$ to optimize the settling of the track/hold before the next conversion is initiated. The diagram shows the read operation and the write operation taking place in parallel. On the sixth falling edge of SCLK in the write sequence the internal pulse will be initiated. Assuming MUX OUT is connected to SHA IN, 2 μs are required between this sixth falling edge of SCLK and the rising edge of $\overline{\text{CONVST}}$ to allow for the full acquisition time of the track/hold amplifier. With the serial clock rate at its maximum of 10 MHz, the achievable throughput rate for the part is 5.9 μs (conversion time) plus 0.6 μs (six serial clock pulses before internal pulse is initiated) plus 2 μs (acquisition time). This results in a minimum throughput time of 8.5 μs (equivalent to a throughput rate of 117 kHz). If the part is operated with a slower serial clock, it will impact the achievable throughput rate for optimum performance.

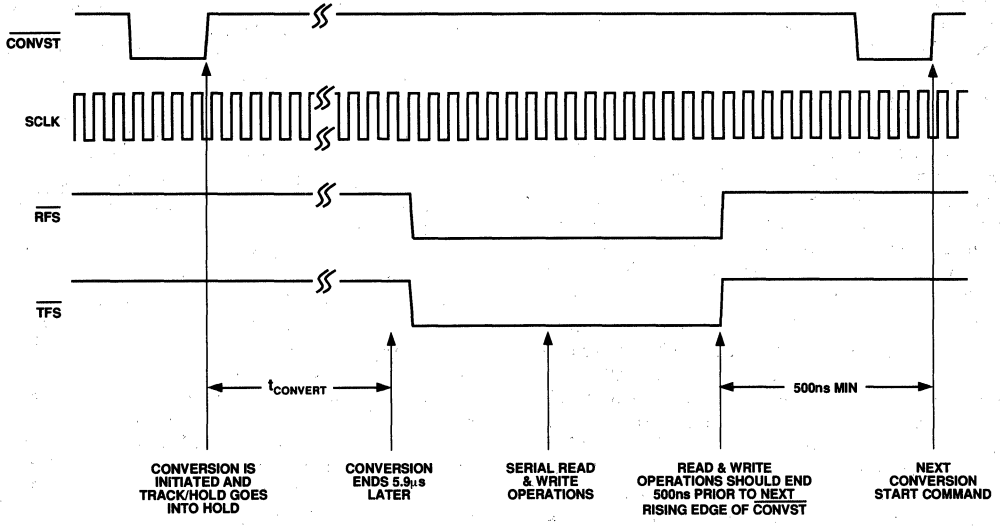

Figure 5. External Clocking (Slave) Mode Timing Sequence for Optimum Performance

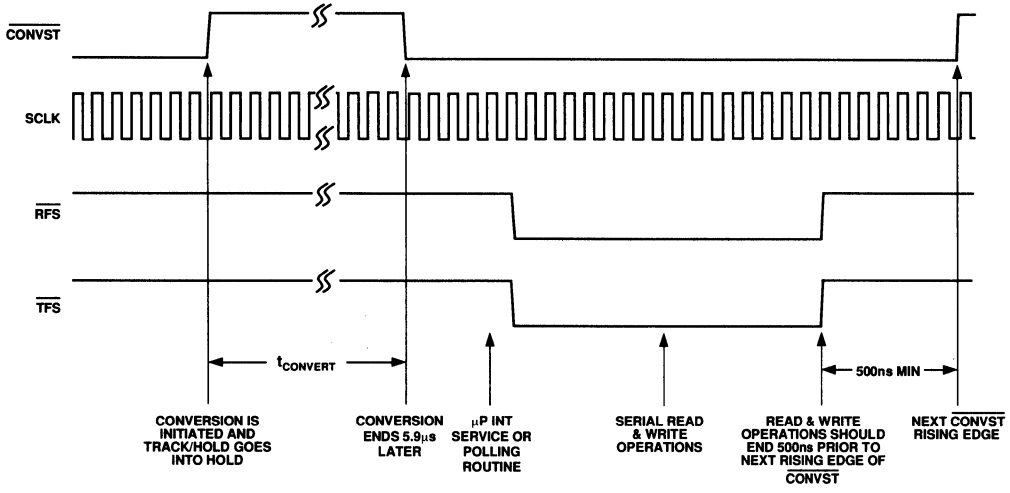

Figure 6. $\overline{CONVST}$ Used as Status Signal in External Clocking Mode

In the Self-Clocking Mode, the AD7890 indicates when conversion is complete by bringing the $\overline{RFS}$ line low and initiating a serial data transfer. In the external clocking mode, there is no indication of when conversion is complete. In many applications, this will not be a problem as the data can be read from the part during conversion or after conversion. However, applications which want to achieve optimum performance from the AD7890 will have to ensure that the data read does not occur during conversion or during 500 ns prior to the rising edge of $\overline{CONVST}$. This can be achieved in either of two ways. The first is to ensure in software that the read operation is not initiated until 5.9 µs after the rising edge of $\overline{CONVST}$. This will only be possible if the software knows when the $\overline{CONVST}$ command is issued. The second scheme would be to use the $\overline{CONVST}$ signal as both the conversion start signal and an interrupt signal. The simplest way to do this would be to generate a square wave signal for $\overline{CONVST}$ with high and low times of 5.9 µs (see Figure 6). Conversion is initiated on the rising edge of $\overline{CONVST}$. The falling edge of $\overline{CONVST}$ occurs 5.9 µs later and can be used as either an active low or falling edge-triggered interrupt signal to tell the processor to read the data from the AD7890. Provided the read operation is completed 500 ns before the rising edge of $\overline{CONVST}$, the AD7890 will operate to specification.

This scheme limits the throughput rate to 11.8 µs minimum. However, depending upon the response time of the microprocessor to the interrupt signal and the time taken by the processor to read the data, this may the fastest which the system could have operated. In any case, the $\overline{CONVST}$ signal does not have to have a 50:50 duty cycle. This can be tailored to optimize the throughput rate of the part for a given system.

Alternatively, the $\overline{CONVST}$ signal can be used as a normal narrow pulse width. The rising edge of $\overline{CONVST}$ can be used as an active high or rising edge-triggered interrupt. A software delay of 5.9 µs can then be implemented before data is read from the part.

C_{EXT} FUNCTIONING

The C_{EXT} input on the AD7890 provides a means of determining how long after a new channel address is written to the part that a conversion can take place. The reason behind this is two-fold. Firstly, when the input channel to the AD7890 is changed, the input voltage on this new channel is likely to be very different from the previous channel voltage. Therefore, the part's track/hold has to acquire the new voltage before an accurate conversion can take place. An internal pulse delays any conversion start command (as well as the signal to send the track/hold into hold) until after this pulse has timed out.
The second reason is to allow the user to connect external anti-aliasing or signal conditioning circuitry between MUX OUT and SHA IN. This external circuitry will introduce extra settling time into the system. The C_{EXT} pin provides a means for the user to extend the internal pulse to take this extra settling time into account. Basically, varying the value of the capacitor on the C_{EXT} pin varies the duration of the internal pulse. Figure 7 shows the relationship between the value of the C_{EXT} capacitor and the internal delay.

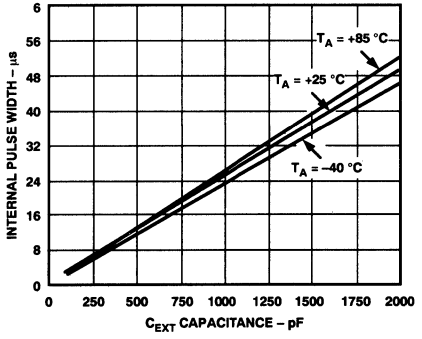

Figure 7. Internal Pulse Width vs. C_{EXT}

The duration of the internal pulse can be seen on the C_{EXT} pin. The C_{EXT} pin goes from a low to a high when a serial write to the part is initiated (on the falling edge of $\overline{TFS}$). It starts to discharge on the sixth falling edge of SCLK in the serial write operation. Once the C_{EXT} pin has discharged to crossing its nominal trigger point of 2.5 V, the internal pulse is timed out.

The internal pulse is initiated each time a write operation to the Control Register takes place. As a result, the pulse is initiated and the conversion process delayed for all software conversion start commands. For hardware conversion start, it is possible to separate the conversion start command from the internal pulse.

If the multiplexer output (MUX OUT) is connected directly to the track/hold input (SHA IN), then no external settling has to be taken into account by the internal pulse width. In applications where the multiplexer is switched and conversion is not initiated until more than 2 μs after the channel is changed (as is possible with a hardware conversion start), the user does not have to worry about connecting any capacitance to the C_{EXT} pin. The 2 μs equates to the track/hold acquisition time of the AD7890. In applications where the multiplexer is switched and conversion is initiated at the same time (such as with a software conversion start), a 120 pF capacitor should be connected to C_{EXT} to allow for the acquisition time of the track/hold before conversion is initiated.

If external circuitry is connected between MUX OUT and SHA IN, then the extra settling time introduced by this circuitry will have to be taken into account. In the case where the multiplexer change command and the conversion start command are separated, they need to be separated by greater than the acquisition time of the AD7890 plus the settling time of the external circuitry if the user does not have to worry about the C_{EXT} capacitance. In applications where the multiplexer is switched and conversion is initiated at the same time (such as with a software conversion start), the capacitor on C_{EXT} needs to allow for the acquisition time of the track/hold plus the settling-time of the external circuitry before conversion is initiated.

SERIAL INTERFACE

The AD7890's serial communications port provides a flexible arrangement to allow easy interfacing to industry-standard microprocessors, microcontrollers and digital signal processors. A serial read to the AD7890 accesses data from the output register via the DATA OUT line. A serial write to the AD7890 writes data to the Control Register via the DATA IN line.

Two different modes of operation are available, optimized for different types of interface where the AD7890 can act either as master in the system (it provides the serial clock and data framing signal) or acts as slave (an external serial clock and framing signal can be provided to the AD7890). These two modes, labelled Self-Clocking Mode and External Clocking Mode, are discussed in detail in the following sections.

Self-Clocking Mode

The AD7890 is configured for its Self-Clocking Mode by tying the SMODE pin of the device to a logic low. In this mode, the AD7890 provides the serial clock signal and the serial data framing signal used for the transfer of data from the AD7890. This Self-Clocking Mode can be used with processors which allow an external device to clock their serial port including most digital signal processors.

Read Operation

Figure 8 shows a timing diagram for reading from the AD7890 in the Self-Clocking mode. At the end of conversion, $\overline{RFS}$ goes low and the serial clock (SCLK) and serial data (DATA OUT) outputs become active. Sixteen bits of data are transmitted with one leading zero, followed by the three address bits of the Control Register, followed by the 12-bit conversion result starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. The $\overline{RFS}$ output remains low for the duration of the sixteen clock cycles. On the sixteenth rising edge of SCLK, the $\overline{RFS}$ output is driven high and DATA OUT is disabled.

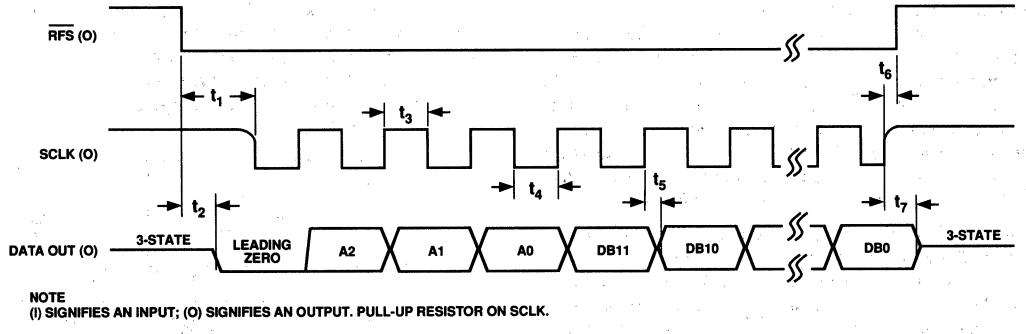

Figure 8. Self-Clocking (Master) Mode Output Register Read

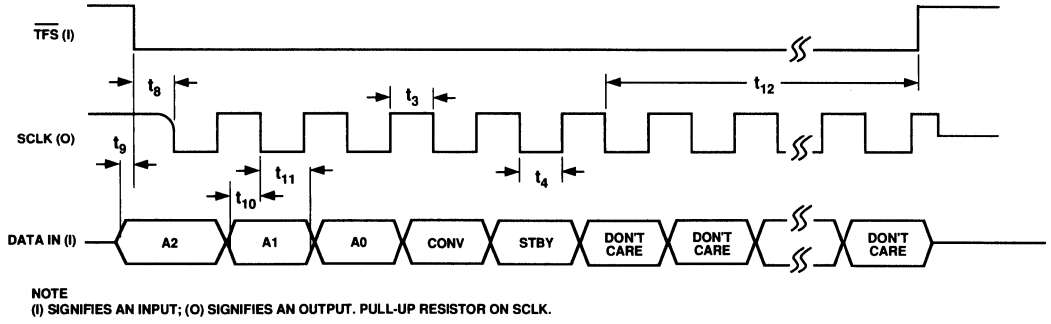

Figure 9. Self-Clocking (Master) Mode Control Register Write

Write Operation

Figure 9 shows a write operation to the Control Register of the AD7890. The $\overline{TFS}$ input is taken low to indicate to the part that a serial write is about to occur. $\overline{TFS}$ going low initiates the SCLK output and this is used to clock data out of the processors serial port and into the Control Register of the AD7890. The AD7890 Control Register requires only five bits of data. These are loaded on the first five clock cycles of the serial clock with data on all subsequent clock cycles being ignored. However, the part requires six serial clock cycles to load data to the Control Register. Serial data to be written to the AD7890 must be valid on the falling edge of SCLK.

External-Clocking Mode

The AD7890 is configured for its external-clocking mode by tying the SMODE pin of the device to a logic high. In this mode, SCLK and $\overline{RFS}$ of the AD7890 are configured as inputs. This external-clocking mode is designed for direct interface to systems which provide a serial clock output which is synchronized to the serial data output including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

Read Operation

Figure 10 shows the timing diagram for reading from the AD7890 in the external-clocking mode. $\overline{RFS}$ goes low to access data from the AD7890. The serial clock input does not have to be continuous. The serial data can be accessed in a number of bytes. However, $\overline{RFS}$ must remain low for the duration of the data transfer operation. Once again, sixteen bits of data are transmitted with one leading zero, followed by the three address bits in the Control Register, followed by the 12-bit conversion result starting with the MSB. If $\overline{RFS}$ goes low during the high time of SCLK, the leading zero is clocked out from the falling edge of $\overline{RFS}$ (as per Figure 10). If $\overline{RFS}$ goes low during the low time of SCLK, the leading zero is clocked out on the next rising edge of SCLK. This ensures that, regardless of whether $\overline{RFS}$ goes low during a high time or low time of SCLK, the leading zero is valid on the first falling edge of SCLK after $\overline{RFS}$ goes low, provided t_{14} and t_{17} are adhered to. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. At the end of the read operation, the DATA OUT line is three-stated by a rising edge on either the SCLK or $\overline{RFS}$ inputs, whichever occurs first. If a serial read from the output register is in progress when conversion is complete, the updating of the output register is deferred until the serial data read is complete and $\overline{RFS}$ returns high.

Write Operation

Figure 11 shows a write operation to the Control Register of the AD7890. As with the Self-Clocking mode, the $\overline{TFS}$ input goes low to indicate to the part that a serial write is about to occur. As before, the AD7890 Control Register requires only five bits of data. These are loaded on the first five clock cycles of the serial clock with data on all subsequent clock cycles being ignored. However, the part requires six serial clocks to load data to the Control Register. Serial data to be written to the AD7890 must be valid on the falling edge of SCLK.

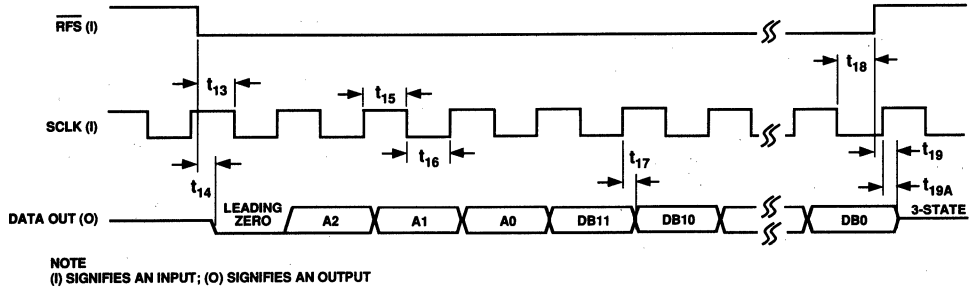

Figure 10. External Clocking (Slave) Mode Output Register Read

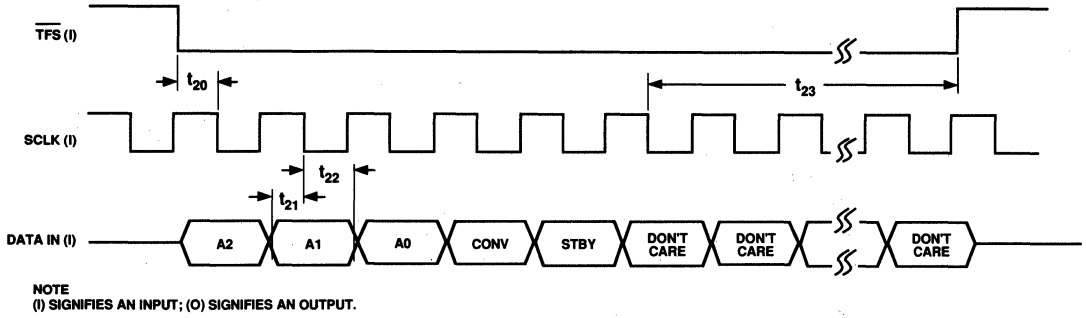

Figure 11. External Clocking (Slave) Mode Control Register Write

SIMPLIFYING THE INTERFACE

To minimize the number of interconnect lines to the AD7890, the user can connect the $\overline{RFS}$ and $\overline{TFS}$ lines of the AD7890 together and read and write from the part simultaneously. In this case, new control register data should be provided on the DATA IN line selecting the input channel and possibly providing a conversion start command while the part provides the result from the conversion just completed on the DATA OUT line.

In the self-clocking mode, this means that the part provides all the signals for the serial interface. It does require that the microprocessor has the data to be written to the Control Register available in its output register when the part brings the $\overline{TFS}$ line low. In the external clocking mode, it means that the user only has to supply a single frame synchronization signal to control both the read and write operations.

Care must be taken with this scheme that the read operation is completed before the next conversion starts if the user wants to obtain optimum performance from the part. In the case of the software conversion start, the conversion command is written to the Control Register on the sixth serial clock edge. However, the read operation continues for another 10 serial clock cycles. To avoid reading during the sampling instant or during conversion, the user should ensure that the internal pulse width is sufficiently long (by choosing C_{EXT}) so that the read operation is completed before the next conversion sequence begins. Failure to do this will result in significantly degraded performance from the part, both in terms of signal-to-noise ratio and dc parameters. In the case of a hardware conversion start, the user should ensure that the delay between the sixth falling edge of the serial clock in the write operation and the next rising edge of $\overline{CONVST}$ is greater than the internal pulse width.

MICROPROCESSOR/MICROCONTROLLER INTERFACE

The AD7890's flexible serial interface allows for easy connection to the serial ports of DSP processors and microcontrollers. Figures 12 through 15 show the AD7890 interfaced to a number of different microcontrollers and DSP processors. In some of the interfaces shown, the AD7890 is configured as the master in the system, providing the serial clock and frame sync for the read operation while in others it acts as a slave with these signals provided by the microprocessor.

AD7890–8051 Interface

Figure 12 shows an interface between the AD7890 and the 8XC51 microcontroller. The AD7890 is configured for its external clocking mode while the 8XC51 is configured for its Mode 0 serial interface mode. The diagram shown in Figure 12 makes no provisions for monitoring when conversion is complete on the AD7890 (assuming hardware conversion start is used). To monitor the conversion time on the AD7890 a scheme such as outlined previously with $\overline{CONVST}$ can be used. This can be implemented in two ways. One is to connect the $\overline{CONVST}$ line to another parallel port bit which is configured as an input. This port bit can then be polled to determine when conversion is complete. An alternative is to use an interrupt driven system in which case the $\overline{CONVST}$ line should be connected to the $\overline{INT1}$ input of the 8XC51.

Since the 8XC51 contains only one serial data line, the DATA OUT and DATA IN lines of the AD7890 must be connected together. This means that the 8XC51 cannot communicate with the output register and Control Register of the AD7890 at the same time. The 8XC51 outputs the LSB first in a write operation so care should be taken in arranging the data which is to be transmitted to the AD7890. Similarly, the AD7890 outputs the MSB first during a read operation while the 8XC51 expects the LSB first. Therefore, the data that is to be read into the serial port needs to be rearranged before the correct data word from the AD7890 is available in the microcontroller.

The serial clock rate from the 8XC51 is limited to significantly less than the allowable input serial clock frequency with which the AD7890 can operate. As a result, the time to read data from the part will actually be longer than the conversion time of the part. This means that the AD7890 cannot run at its maximum throughput rate when used with the 8XC51.

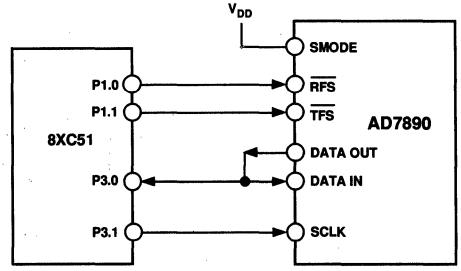

Figure 12. AD7890 to 8XC51 Interface

AD7890–68HC11 Interface

An interface circuit between the AD7890 and the 68HC11 microcontroller is shown in Figure 13. For the interface shown, the AD7890 is configured for its external clocking mode while the 68HC11's SPI port is used and the 68HC11 is configured in its single-chip mode. The 68HC11 is configured in the master mode with its CPOL bit set to a logic zero and its CPHA bit set to a logic one.

As with the previous interface, there are no provisions for monitoring when conversion is complete on the AD7890. To monitor the conversion time on the AD7890 a scheme, such as outlined in the previous interface with $\overline{\text{CONVST}}$, can be used. This can be implemented in two ways. One is to connect the $\overline{\text{CONVST}}$ line to another parallel port bit which is configured as an input. This port bit can then be polled to determine when conversion is complete. An alternative is to use an interrupt driven system in which case the $\overline{\text{CONVST}}$ line should be connected to the $\overline{\text{IRQ}}$ input of the 68HC11.

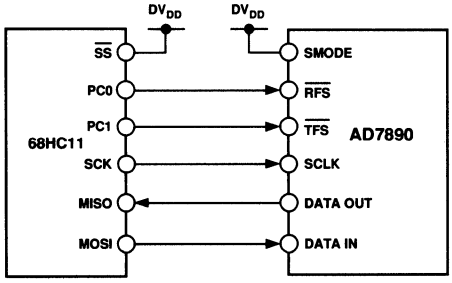

Figure 13. AD7890 to 68HC11 Interface

The serial clock rate from the 68HC11 is limited to significantly less than the allowable input serial clock frequency with which the AD7890 can operate. As a result, the time to read data from the part will actually be longer than the conversion time of the part. This means that the AD7890 cannot run at its maximum throughput rate when used with the 68HC11.

AD7890–ADSP-2101 Interface

An interface circuit between the AD7890 and the ADSP-2101 DSP processor is shown in Figure 14. The AD7890 is configured for its external clocking mode with the ADSP-2101 providing the serial clock and frame synchronization signals. The RFS1 and TFS1 inputs are outputs are configured for active low operation.

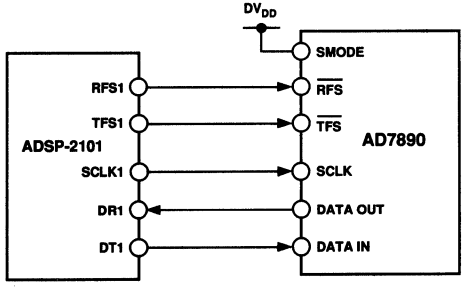

Figure 14. AD7890 to ADSP-2101 Interface

In the scheme shown, the maximum serial clock frequency which the ADSP-2101 can provide is 6.25 MHz. This allows the AD7890 to be operated at a sample rate of 111 kHz. If it is desirable to operate the AD7890 at its maximum throughput rate of 117 kHz, an external serial clock of 10 MHz can be provided to drive the serial clock input of both the AD7890 and the ADSP-2101.

To monitor the conversion time on the AD7890 a scheme, such as outlined in previous interfaces with $\overline{\text{CONVST}}$, can be used. This can be implemented by connecting the $\overline{\text{CONVST}}$ line directly to the $\overline{\text{IRQ2}}$ input of the ADSP-2101. An alternative to this, where the user does not have to worry about monitoring the conversion status, is to operate the AD7890 in its Self-Clocking Mode. In this scheme, the actual interface connections would remain the same as in Figure 14 but now the AD7890 provides the serial clock and receive frame synchronization signals. Using the AD7890 in its Self-Clocking Mode, limits the throughput rate of the system as the serial clock rate is limited to 2.5 MHz.

AD7890–DSP56000 Interface

Figure 15 shows an interface circuit between the AD7890 and the DSP56000 DSP processor. The AD7890 is configured for its external clocking mode. The DSP56000 is configured for normal mode, synchronous operation with continuous clock. It is also set up for a 16-bit word with SCK and SC2 as outputs. The FSL bit of the DSP56000 should be set to 0.

The $\overline{\text{RFS}}$ and $\overline{\text{TFS}}$ inputs of the AD7890 are connected together so data is transmitted to and from the AD7890 at the same time. With the DSP56000 in synchronous mode, it provides a common frame synchronization pulse for read and write operations on its SC2 output. This is inverted before being applied to the $\overline{\text{RFS}}$ and $\overline{\text{TFS}}$ inputs of the AD7890.

To monitor the conversion time on the AD7890 a scheme, such as outlined in previous interface examples with $\overline{\text{CONVST}}$, can be used. This can be implemented by connecting the $\overline{\text{CONVST}}$ line directly to the $\overline{\text{IRQA}}$ input of the DSP56000.

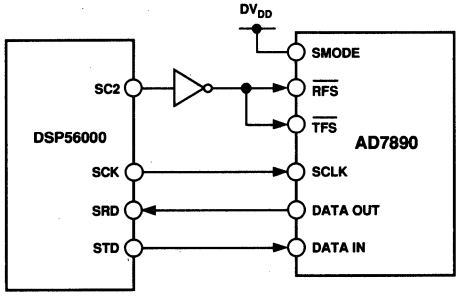

Figure 15. AD7890 to DSP56000 Interface

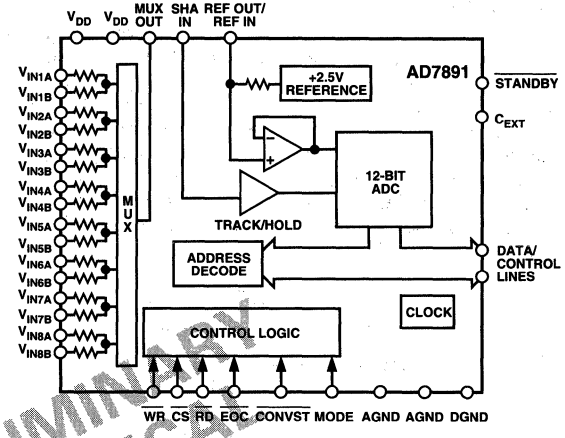
LC²MOS 8-Channel, 12-Bit High Speed Data Acquisition System

AD7891

FEATURES

Fast 12-Bit ADC with 1.6 μs Conversion Time
Eight Single-Ended Analog Input Channels
Selection of Input Ranges:
±5 V, ±10 V for AD7891-1
0 V to +2.5 V, 0 to +5 V ±2.5 V for AD7891-2
Parallel and Serial Interface
Allows Separate Access to Mux and ADC
On-Chip Track/Hold Amplifier
On-Chip Reference
Single Supply, Low Power Operation (75 mW max)
Power-Down Mode (75 μW typ)
Overvoltage Protection on Analog Inputs

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7891 is an eight-channel 12-bit data acquisition system with a choice of either parallel or serial interface structure. The part contains an input multiplexer, an on-chip track/hold amplifier, a high speed 12-bit ADC, a +2.5 V reference and a high speed interface. The part operates from a single +5 V supply and accepts a variety of analog input ranges across two models, the AD7891-1 (±5 V and ±10 V) and the AD7891-2 (0 V to +2.5 V, 0 V to +5 V and ±2.5 V).

The multiplexer on the part is independently accessible. As a result, an antialiasing filter or signal conditioning can be inserted, if required, between the multiplexer and the ADC. This allows one antialiasing filter to be used for all eight channels. The value of an external capacitor determines the time given to the multiplexer settling to allow for any external delays in the filter or signal conditioning circuitry.

The AD7891 provides the option of either a parallel interface or serial interface structure determined by the MODE pin. The part has standard control inputs and fast data access times for both the serial and parallel interfaces which ensures easy interfacing to modern microprocessors, microcontrollers and digital signal processors.

In addition to the traditional dc accuracy specifications such as linearity, full-scale and offset errors, the part is also specified for dynamic performance parameters including harmonic distortion and signal-to-noise ratio.

Power dissipation in normal mode is 60 mW typical while in the standby mode this is reduced to 75 μW typ. The AD7891 is fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 44-pin plastic quad flatpack (PQFP) and a 44-lead plastic leaded chip carrier (PLCC).

PRODUCT HIGHLIGHTS

1. The AD7891 is a complete monolithic 12-bit data acquisition system combining an eight-channel multiplexer, 12-bit ADC, +2.5 V reference and track/hold amplifier on a single chip.
2. The part provides separate access to the multiplexer and the ADC, thus retaining all the flexibility of separate multiplexer and ADC solutions.
3. The part offers high speed parallel or serial interface options for easy connection to microprocessors, microcontrollers and digital signal processors.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

SPECIFICATIONS

NOTES

[1]Temperature ranges are as follows: A, B Versions: –40°C to +85°C; S Version: –55°C to +125°C.

[2]AD7891-1's dynamic performance is measured with an input frequency of 10 kHz while the AD7891-2's dynamic performance is measured with an input frequency of 100 kHz.

[3]See Terminology.

[4]This sample rate can only be achieved when the part is operated in the parallel interface mode. Maximum achievable throughput rate in the serial interface mode is 385 kHz.

[5]Sample tested @ +25°C to ensure compliance.

[6]REF IN must be buffered before being applied to V_{INXB}.

Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7891 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are measured with tr = tf = 1 ns (10% to 90% of +5 V) and timed from a voltage level of +1.6 V.
[2]See Figures 2 and 3.
[3]Specified using 10% and 90% points on the waveform of interest.
[4]Measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.0 V.
[5]These times are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.
Specifications subject to change without notice.

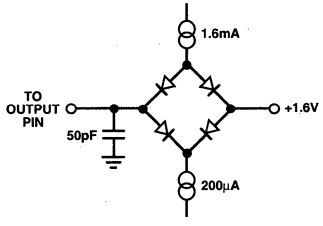

Figure 1. Load Circuit for Access Time and Bus Relinquish Time

PIN DESCRIPTION

Mnemonic	Description
V_{INXA}, V_{INXB}	Analog Input Channels. The AD7891 contains eight pairs of analog input channels. Each channel contains two input pins to allow a number of different input ranges to be used with the AD7891. There are two possible input voltage ranges on the AD7891-1. The ±5 V input range is selected by connecting the input voltage to both V_{INXA} and V_{INXB}, while the ±10 V input range is selected by applying the input voltage to V_{INXA} and connecting V_{INXB} to AGND. The AD7891-2 has three possible input ranges. The 0 V to +2.5 V input range is selected by connecting the analog input voltage to both V_{INXA} and V_{INXB}; the 0 V to +5 V input range is selected by applying the input voltage to V_{INXA} and connecting V_{INXB} to AGND; while the ±2.5 V input range is selected by connecting the analog input voltage to V_{INXA} and connecting V_{INXB} to REF IN (provided this REF IN voltage comes from a low impedance source). The channel to be converted is selected by the A2, A1 and A0 bits of the Control Register. In the parallel interface mode, these bits are available as three data input lines (DB3 to DB5) in a parallel write operation, while in the serial interface mode, these three bits are accessed via the DATA IN line in a serial write operation. The multiplexer has guaranteed break-before-make operation.
V_{DD}	Positive supply voltage, +5 V ± 5%.
AGND	Analog Ground. Ground reference for track/hold, comparator and DAC.
DGND	Digital Ground. Ground reference for digital circuitry.
$\overline{\text{STANDBY}}$	Standby Mode Input. TTL-compatible input which is used to put the device into the power save or standby mode. The $\overline{\text{STANDBY}}$ input is high for normal operation and low for standby operation.
MUX OUT	Multiplexer Output. The output of the multiplexer appears at this pin. The output voltage range from this output is 0 V to +2.5 V for the nominal analog input range to the selected channel. The output impedance of this output is nominally 7.5 kΩ for the AD7891-1 and 1 kΩ for the AD7891-2. If no external antialiasing filter or signal conditioning is required, MUX OUT should be connected to SHA IN.
SHA IN	Track/Hold Input. The input to the on-chip track/hold is applied to this pin. It is a high impedance input and the input voltage range is 0 V to +2.5 V.
C_{EXT}	External capacitor. An external capacitor is connected to this pin to determine the length of the internal pulse (see C_{EXT} FUNCTIONING section). Larger capacitances on this pin extend the pulse to allow for settling-time delays through an external antialiasing filter.
REF OUT/REF IN	Voltage Reference Output/Input. The part can either be used with its own internal reference or with an external reference source. The on-chip +2.5 V reference voltage is provided at this pin. When using this internal reference as the reference source for the part, REF OUT should be decoupled to AGND with a 0.1 µF disc ceramic capacitor. The output impedance of the reference source is typically 2 kΩ. When using an external reference source as the reference voltage for the part, the reference source should be connected to this pin. This overdrives the internal reference and provides the reference source for the part. The reference pin is buffered on-chip but must be able to sink or source current through this 2 kΩ resistor to the output of the on-chip reference. The nominal reference voltage for correct operation of the AD7891 is +2.5 V.
$\overline{\text{CONVST}}$	Convert Start. Edge-triggered logic input. A low to high transition on this input puts the track/hold into hold and initiates conversion. This CONVST signal is not gated with the internal pulse (see C_{EXT} FUNCTIONING section) and so the conversion is initiated from the rising edge of CONVST regardless of whether the internal pulse has timed out or not.
$\overline{\text{EOC}}$	End-of-Conversion. Active low logic output indicating converter status. The end of conversion is signified by a low going pulse on this line. The duration of this $\overline{\text{EOC}}$ pulse is nominally 120 ns.
MODE	Interface Mode. Control input which determines the interface mode for the part. With this pin at a logic low, the AD7891 is in its serial interface mode; with this pin at a logic high, the device is in its parallel interface mode.

PARALLEL INTERFACE MODE FUNCTIONS

Mnemonic	Description
$\overline{CS}$	Chip Select. Active low logic input which is used in conjunction with $\overline{RD}$ to enable the data outputs and with $\overline{WR}$ to allow input data to be written to the part.
$\overline{RD}$	Read. Active low logic input which is used in conjunction with $\overline{CS}$ low to enable the data outputs.
$\overline{WR}$	Write Input. Active low, logic input used in conjunction with $\overline{CS}$ to latch the multiplexer address. The rising edge of this input also initiates an internal pulse, the width of which is determined by the value of capacitance on the C_{EXT} pin. When this pulse is active, it gates off the software conversion start until the pulse has timed out. This allows an external antialiasing filter (the output of which is applied to SHA IN) to settle when a channel address is changed before the track/hold goes into hold and conversion is initiated. If the SWCON bit of the Control Register is set to 1, when this pulse times out, the track/hold then goes into hold and conversion is initiated. If the SWCON bit of the Control Register is set to 0, the track/hold and conversion sequence are unaffected by the $\overline{WR}$ operation.

5

Data I/O Lines

There are twelve data input/output lines on the AD7891. When the part is configured for parallel mode (MODE = 1), the output data from the part is provided at these 12 pins during a read operation. For a write operation in parallel mode, these lines provide access to the part's Control Register.

Parallel Read Operation

During a parallel read operation the 12 lines become the 12 data bit containing the conversion result from the AD7891. These data bits are labelled Data Bit 0 (LSB) to Data Bit 11 (MSB). They are three-state TTL-compatible outputs. Output data coding is 2s complement when the DATA FORMAT Bit of the Control Register is 1 and straight binary when the DATA FORMAT Bit of the Control Register is 0.

Mnemonic	Description
DB0–DB11	Data Bit 0 (LSB) to Data Bit 11 (MSB). Three state TTL-compatible outputs which are controlled by the $\overline{CS}$ and $\overline{RD}$ inputs.

Parallel Write Operation

During a parallel write operation the following functions can be written to the Control Register via the 12 data input/output pins.

Mnemonic	Description
A0	Address Input. The status of this input during a parallel write operation is latched to the A0 bit of the Control Register (see Control Register section).
A1	Address Input. The status of this input during a parallel write operation is latched to the A1 bit of the Control Register (see Control Register section).
A2	Address Input. The status of this input during a parallel write operation is latched to the A2 bit of the Control Register (see Control Register section).
SWCON	Software Conversion Start. The status of this input during a parallel write operation is latched to the SWCONV bit of the Control Register (see Control Register section).
SWSTBY	Software Standby Control. The status of this input during a parallel write operation is latched to the SWSTBY bit of the Control Register (see Control Register section).
FORMAT	Data Format Selection. The status of this input during a parallel write operation is latched to the FORMAT bit of the Control Register (see Control Register section).

SERIAL INTERFACE MODE FUNCTIONS

When the part is configured for serial mode (MODE = 0), five of the twelve data input/output lines provide serial interface functions. These functions are outlined below.

Mnemonic	Description
SCLK	Serial Clock Input. This is an externally applied serial clock which is used to load serial data to the Control Register and to access data from the output register.
$\overline{TFS}$	Transmit Frame Synchronization Pulse. Active low logic input with serial data expected after the falling edge of this signal.

$\overline{RFS}$	Receive Frame Synchronization Pulse. This is an active low logic input with $\overline{RFS}$ provided externally as a strobe or framing pulse to access serial data from the output register. For applications which require that data be transmitted and received at the same time, $\overline{RFS}$ and $\overline{TFS}$ should be connected together.
DATA OUT	Serial Data Output. Sixteen bits of serial data are provided with the DATA FORMAT bit and the three address bits of the Control Register preceding the 12 bits of conversion data. Serial data is valid on the falling edge of SCLK for sixteen edges after $\overline{RFS}$ goes low. Output conversion data coding is 2s complement when the DATA FORMAT Bit of the Control Register is 1 and straight binary when the DATA FORMAT Bit of the Control Register is 0.
DATA IN	Serial Data Input. Serial data to be loaded to the Control Register is provided at this input. The first six bits of serial data are loaded to the Control Register on the first six falling edges of SCLK after $\overline{TFS}$ goes low. Serial data on subsequent SCLK edges is ignored while $\overline{TFS}$ remains low.

*S = Plastic Quad Flatpack (PQFP); P = Plastic Leaded Chip Carrier (PLCC). For outline information see Package Information section.

CONTROL REGISTER

The Control Register for the AD7891 contains 6 bits of information as described below. These 6 bits can be written to the Control Register either in a parallel mode write operation or via a serial mode write operation. The default (power-on) condition of all bits in the Control Register is 0.

MSB

A2	A1	A0	SWCONV	SWSTBY	FORMAT

A2	Address Input. This input is the most significant address input for multiplexer channel selection.
A1	Address Input. This is the 2nd most significant address input for multiplexer channel selection.
A0	Address Input. Least significant address input for multiplexer channel selection. When the address is written to the control register, an internal pulse is initiated, the pulse width of which is determined by the value of capacitance on the C_{EXT} pin. SWCON will not sample the input signal or initiate a conversion until this pulse has timed out. This allows for the multiplexer settling time and track/hold acquisition time before the track/hold goes into hold and conversion is initiated. In applications where there is an antialiasing filter between MUX OUT and SHA IN, the filter settling time can be taken into account before the input at SHA IN is sampled. When the internal pulse times out, the track/hold goes into hold and conversion is initiated.
SWCONV	Conversion Start. Writing a 1 to this bit initiates a conversion in a similar manner to the $\overline{\text{CONVST}}$ input. Continuous conversion starts do not take place when there is a 1 in this location. The internal pulse and the conversion process are initiated when a 1 is written to this bit. With a 1 in this bit, the hardware conversion start, i.e., the $\overline{\text{CONVST}}$ input, is disabled. Writing a 0 to this bit enables the hardware $\overline{\text{CONVST}}$ input.
SWSTBY	Standby Mode Input. Writing a 1 to this bit places the device in its standby or power-down mode. Writing a 0 to this bit places the device in its normal operating mode.
FORMAT	Data Format. Writing a 0 to this bit determines that the conversion data output format is straight (natural) binary. This data format is generally be used for unipolar input ranges. Writing a 1 to this bit determines that the conversion data output format is 2s complement. This output data format is generally used for bipolar input ranges.

CIRCUIT DESCRIPTION

The AD7891 is an eight-channel, high speed, 12-bit data acquisition system. It provides the user with signal scaling, multiplexer, track/hold, reference, A/D converter and high speed parallel and serial interface logic functions on a single chip. The signal conditioning on the AD7891-1 allows the part to accept analog input ranges of ±5 V or ±10 V when operating from a single supply. The input circuitry on the AD7891-2 allows the part to handle input signal ranges of 0 V to +2.5 V, 0 V to +5 V and ±2.5 V again while operating from a single +5 V supply. The part requires a +2.5 V reference which can be provided from the part's own internal reference or from an external reference source.

Unlike other single chip solutions, the AD7891 provides the user with separate access to the multiplexer and the A/D converter. This means that the flexibility of separate multiplexer and ADC solutions is not sacrificed with the one-chip solution. With access to the multiplexer output, the user can implement external signal conditioning between the multiplexer and the track/hold. It means that one antialiasing filter can be used on the output of the multiplexer to provide the antialiasing function for all eight channels. The extra settling time introduced into the circuit by the external circuitry can be allowed for by the AD7891 by connecting a single capacitor to the C_{EXT} pin. If no external signal conditioning is required, the multiplexer output (MUX OUT) can simply be connected directly to the track/hold input (SHA IN).

Conversion is initiated on the AD7891 either by pulsing the $\overline{\text{CONVST}}$ input or by writing a logic 1 to the SWCONV bit of the Control Register. When using the hardware $\overline{\text{CONVST}}$ input, the on-chip track/hold goes from track to hold mode and the conversion sequence is started on the rising edge of the $\overline{\text{CONVST}}$ signal. When a software conversion start is initiated, an internal pulse is generated which delays the track/hold acquisition point and the conversion start sequence until the pulse is timed out. This internal pulse is initiated (goes from low to high) whenever a write to the AD7891 Control Register takes place with a 1 in the SWCONV bit. It then starts to discharge and the track/hold cannot go into hold and conversion cannot be initiated until the C_{EXT} pin has crossed its trigger point of 2.5 V. The discharge time of the voltage on C_{EXT} depends upon the value of capacitor connected to the C_{EXT} pin.

The conversion clock for the part is internally generated and conversion time for the AD7891 is 1.6 µs from the rising edge of the hardware $\overline{\text{CONVST}}$ signal, and the track/hold acquisition time for the part is 400 ns. To obtain optimum performance from the part, the data read operation should not occur during the conversion or during 200 ns prior to the next conversion. This allows the part to operate at throughput rates up to 500 ksps in the parallel mode and achieve data sheet specifications. In the serial mode, the maximum achievable throughput rate for the part is 385 ksps (assuming a 20 MHz serial clock).

INTERFACE INFORMATION

The AD7891 provides two interface options, a 12-bit parallel interface and a high speed serial interface. The required interface mode is selected via the MODE pin. The two interface modes are discussed in the following sections.

Parallel Interface Mode

The parallel interface mode is selected by tying the MODE input to a logic high. Figure 2 shows a timing diagram illustrating the operational sequence of the AD7891 in parallel mode for a hardware conversion start. The multiplexer address is written to the AD7891 on the rising edge of the $\overline{WR}$ input. The on-chip track/hold goes into hold mode on the rising edge of $\overline{CONVST}$, and conversion is also initiated at this point. When conversion is complete, the end of conversion line ($\overline{EOC}$) pulses low to indicate that new data is available in the AD7891's output register. This $\overline{EOC}$ line can be used to drive an edge-triggered interrupt of a microprocessor. $\overline{CS}$ and $\overline{RD}$ going low accesses the 12-bit conversion result. In systems where the part is interfaced to a gate array or ASIC, this $\overline{EOC}$ pulse can be applied to the $\overline{CS}$ and $\overline{RD}$ inputs to latch data out of the AD7891 and into the gate array or ASIC. This means that the gate array or ASIC does not need any conversion status recognition logic, and it also eliminates the logic required in the gate array or ASIC to generate the read signal for the AD7891.

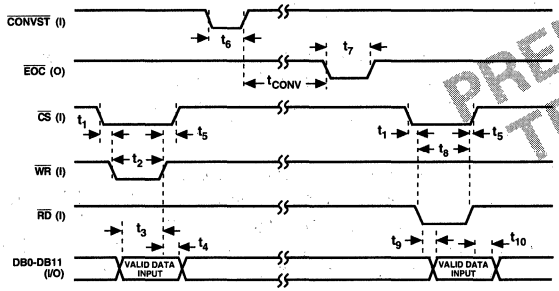

Figure 2. Parallel Mode Timing Diagram

Serial Interface Mode

The serial interface mode is selected by tying the MODE input to a logic low. In this case, five of the data/control inputs of the parallel mode assume serial interface functions. The serial interface on the AD7891 is a five-wire interface with read and write capabilities, with data being read from the output register via the DATA OUT line and data being written to the Control Register via the DATA IN line. The part operates in a slave or external clocking mode and requires an externally applied serial clock to the SCLK input to access data from the data register or write data to the control register. There are separate framing signals for the read ($\overline{RFS}$) and write ($\overline{TFS}$) operations.

Read Operation

Figure 3 shows the timing diagram for reading from the AD7891 in serial mode. $\overline{RFS}$ goes low to access data from the AD7891. The serial clock input does not have to be continuous. The serial data can be accessed in a number of bytes. However, $\overline{RFS}$ must remain low for the duration of the data transfer operation. Sixteen bits of data are transmitted in serial mode with the data FORMAT bit, followed by the three address bits in the Control Register, followed by the 12-bit conversion result starting with the MSB. Serial data is clocked out of the device on the rising edge of SCLK and is valid on the falling edge of SCLK. At the end of the read operation, the DATA OUT line is three-stated by a rising edge on either the SCLK or $\overline{RFS}$ inputs, whichever occurs first.

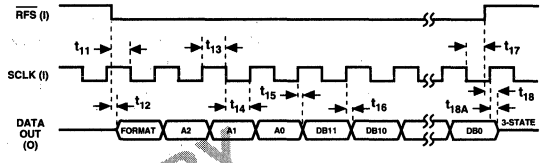

Figure 3. Serial Mode Read Operation

Write Operation

Figure 4 shows a write operation to the Control Register of the AD7891. The $\overline{TFS}$ input goes low to indicate to the part that a serial write is about to occur. The AD7891 Control Register requires only six bits of data. These are loaded on the first six clock cycles of the serial clock with data on all subsequent clock cycles being ignored. Serial data to be written to the AD7891 must be valid on the falling edge of SCLK.

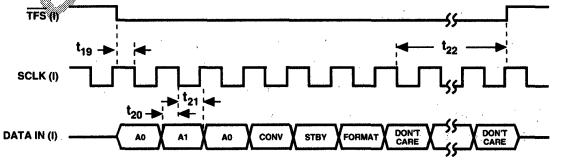

Figure 4. Serial Mode Write Operation

Simplifying the Serial Interface

To minimize the number of interconnect lines to the AD7891 in serial mode, the user can connect the $\overline{RFS}$ and $\overline{TFS}$ lines of the AD7891 together and read and write from the part simultaneously. In this case, new Control Register data line selecting the input channel and providing a conversion start command should be provided on the DATA IN while the part provides the result from the conversion just completed on the DATA OUT line.

C_{EXT} FUNCTIONING

The C_{EXT} input on the AD7891 provides a means of determining how long after a new channel address is written to the part that a conversion can take place. The reason behind this is twofold. First, when the input channel to the AD7891 is changed, the input voltage on this new channel is likely to be very different from the previous channel voltage. Therefore, the part's track/hold has to acquire the new voltage before an accurate conversion can take place. An internal pulse delays any software conversion start command (as well as the signal to send the track/hold into hold) until after this pulse has timed out.

The second reason is to allow the user to connect external antialiasing or signal conditioning circuitry between MUX OUT and SHA IN. This external circuitry will introduce extra settling time into the system. The C_{EXT} pin provides a means for the user to extend the internal pulse to take this extra settling time into account. Basically, varying the value of the capacitor on the C_{EXT} pin varies the duration of the internal pulse.

The duration of the internal pulse can be seen on the C_{EXT} pin. The C_{EXT} pin goes from a low to a high when a software conversion start is written to the part. Once the C_{EXT} pin has discharged to crossing its nominal trigger point of 2.5 V, the internal pulse is timed out. With no capacitor on the C_{EXT} pin, the internal pulse duration is 600 ns.

If the multiplexer output (MUX OUT) is connected directly to the track/hold input (SHA IN), then external settling need not be taken into account by the internal pulse width. In this case, the 600 ns internal pulse duration with no C_{EXT} is sufficient to cater for the 400 ns acquisition time. If external circuitry is connected between MUX OUT and SHA IN, then the extra settling time introduced by this circuitry will have to be taken into account by placing a larger value of capacitance on the C_{EXT} pin.

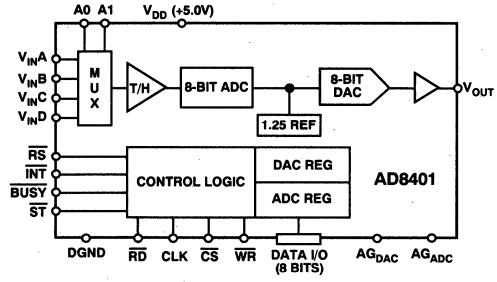
Process Control Equipment

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD8401 is a complete data acquisition and control system containing ADC, DAC, 4-channel MUX, and internal voltage reference. Built using CBCMOS, this monolithic circuit offers the user a complete system with very high package density and reliability.

The converter is a successive approximation ADC with T/H, and is capable of operating with conversion times as short as 2 μs. Analog input bandwidth is 200 kHz, and DAC output voltage settling time is less than 4 μs, making the AD8401 capable of controlling servo loops with speed and precision.

The 8-bit data interface provides both read and write operation for parallel bus interfaces to microcontrollers and DSP processors. An external 5 MHz clock sets the 2 μs conversion rate. Slower clocks reduce the conversion time and the internal power dissipation. The standard control lines: Reset, Busy, Interrupt, Read and Write complete the handshaking signals for microprocessor communication. A start trigger $\overline{ST}$ input allows precise sampling intervals in synchronous sampling applications.

The input multiplexer addressing is designed for direct interface to the AD899 hard-disk drive, read-channel device with no extra hardware or special software. Analog input range levels are likewise compatible with the AD899.

The AD8401 is designed to operate from a single +5 volt supply, which will give an ADC input range of 0 V to 3.0 V, and DAC output range of 0 V to 2.5 V.

The AD8401 is offered in the SOIC-28 surface mount package, and is guaranteed to operate over the extended industrial temperature range of −40°C to +85°C.

NOTES
[1]All input control signals are specified with t_R = t_F = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.
[2]t_{13} and t_{17} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross either 0.8 V or 2.4 V.
[3]t_{14} is defined as the time required for the data line to change 0.5 V when loaded with the circuit of Figure 2.
[4]t_{11} is determined by t_{13}.

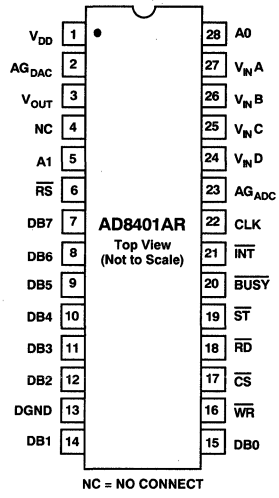
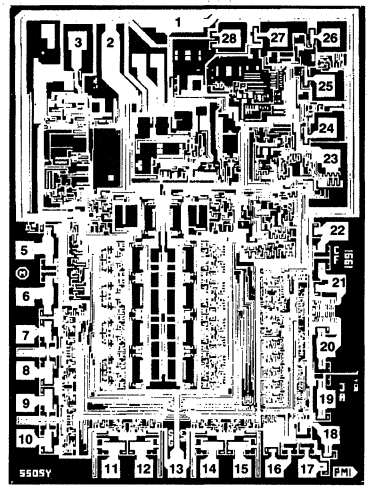
PIN CONFIGURATION



NC = NO CONNECT

DICE CHARACTERISTICS



Die Size 91 X 121 mil = 11,011 sq mil

PIN DESCRIPTIONS

Pin#	Name	Description
1	V_{DD}	Positive Supply. Nominal value +5 volts. This pad requires 2 bonds for die assembly. The substrate is common with V_{DD}.
2	AG_{DAC}	Analog Ground for the DAC. There is a separate analog ground for the ADC.
3	V_{OUT}	Voltage Output from the DAC.
4	NC	No Connect.
5	A1	Address Input that controls multiplexer. See Table I for address decode.
6	RESET ($\overline{RS}$)	Active Low Digital Input that clears the DAC register to zero, setting the DAC to minimum scale. It also asynchronously clears the $\overline{INT}$ line of the ADC.
7–12, 14, 15	DB7 to DB0	Digital I/O Lines. DB7 (7) is the Most Significant Bit (MSB), for both the ADC and the DAC, and DB0 (15) is the Least Significant Bit (LSB).
13	DGND	Digital Ground.
16	$\overline{WR}$	Rising Edge Triggered Write Input. Used to load data into the DAC register.
17	$\overline{CS}$	Chip Select. Active Low Input
18	$\overline{RD}$	Active Low Read Input. When this input is active, ADC data can be read from the part. $\overline{RD}$ going low starts the ADC conversion.
19	$\overline{ST}$	Falling Edge Triggered Start Input. Used for applications requiring precise sample timing. The falling edge of $\overline{ST}$ starts the conversion and sets the $\overline{BUSY}$ low. The $\overline{ST}$ is not gated by $\overline{CS}$.
20	$\overline{BUSY}$	ADC Active Low, Status Output. When the ADC is performing a conversion, the $\overline{BUSY}$ output is low.
21	$\overline{INT}$	Active Low Output. The Interrupt output notifies the system that the ADC has completed its conversion. $\overline{INT}$ goes high on the rising edge of $\overline{CS}$ or $\overline{RD}$. It will also be forced high when RESET is asserted.
22	CLK	External Clock Input Pin. Accepts a TTL or 5 V CMOS input logic levels.
23	AG_{ADC}	Analog ADC Ground
27–24	V_{IN}A, B, C, D	Four Analog Inputs
28	A0	Address input that controls multiplexer. See Table I for address decode.

OPERATION

The AD8401 is a complete data acquisition and control system. It contains the DAC, a four channel input multiplexer, a track/hold, an ADC, as well as an internal bandgap reference. It interfaces to the microcontroller via an 8-bit digital I/O port.

D/A CONVERTER SECTION

The DAC is an 8-bit voltage mode DAC with an output that swings from AG_{DAC} to the 1.25 volt bandgap voltage. It uses an R-2R ladder fed by PNP current sources which allow the output to swing to ground so that the DAC operates in a unipolar mode.

AMPLIFIER SECTION

The DAC's output is buffered by an internal high speed op amp. The op amps output range is set at 0 V to 2.5 V. The op amp has a 500 ns typical settling time to 0.2% for positive slewing signals. There are differences in settling time for negative slewing signals. Signals going to zero volts will settle slightly slower to ground than is seen in the positive direction.

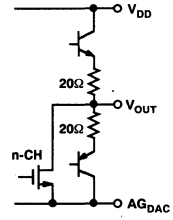


Figure 3. Equivalent Amplifier Output Stage

Current sinking capability is also limited near zero volts in single supply operation. Figure 3 provides an equivalent amplifier output stage schematic.

INTERNAL REFERENCE

An on-chip bandgap is provided as a voltage reference to both the DAC and the ADC. This reference is internal to the AD8401 and is not accessible to the user. It is laser trimmed for both absolute accuracy and temperature coefficients. The reference is internally buffered by a separate control amplifier for both the DAC and ADC to improve isolation between the converters.

DIGITAL I/O

The 8-bit parallel data I/O port on the AD8401 provides access to both the DAC and the ADC. This port is TTL/CMOS compatible with three-state outputs that are ESD protected.

The data format is binary. This data coding applies to both the DAC and the ADC. See the applications information section.

ADC SECTION

A fast successive approximation ADC is used to attain a conversion time of 2 microseconds. Start of conversion is initiated by $\overline{CS}$ and $\overline{RD}$. Following a Start command the $\overline{BUSY}$ signal will become active and another Start command should not be given until the conversion is complete.

The RESET ($\overline{RS}$) input does not affect A/D conversion, but the $\overline{INT}$ (Interrupt or conversion complete) which normally goes active low at the end of a conversion will be forced high by RESET asynchronously.

Figure 4 shows the wave forms for a conversion cycle. The track and hold begins holding the input voltage V_{IN} approximately 50 ns after the falling edge of the Start command. The MSB decision is made approximately 50 ns after the second falling edge of the CLK. If t_X is greater than 50 ns, then the falling edge of the CLK will be seen as the first falling clock edge. If t_X is less than 50 ns, the first MSB conversion will not occur until one clock cycle later. The following bits will each be converted in a similar manner 50 ns after each CLK edge until all eight bits have been converted. After the end of conversion the contents of the ADC SAR register are transferred to the output data latch, the track and hold is returned to the track mode, $\overline{INT}$ goes low and the SAR is reset.

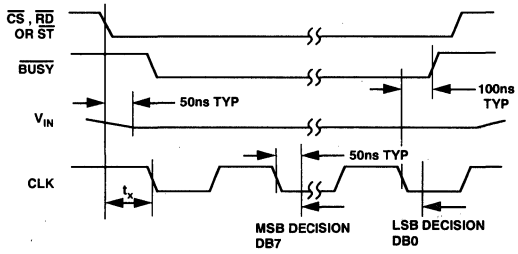

Figure 4. Operating Waveforms Using the External Clock

ANALOG INPUT

The analog inputs of the AD8401 are fed into resistor voltage-divider networks with a typical value of 8.5 kΩ. The amplifiers driving these inputs must have an output resistance low enough to drive these nodes without losing accuracy. Taps from the voltage dividers are connected to the track and hold amplifier by the multiplexer switches.

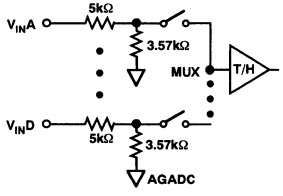

Figure 5. Equivalent Analog Input Circuit

TRACK-AND-HOLD AMPLIFIER

Following the resistive divider at the input of the AD8401 is a track-and-hold amplifier that captures input signals accurately up to the 200 kHz Nyquist frequency of the ADC. To attain this performance the T/H amplifier must have a much greater bandwidth than the signal of interest. Because of this the user must be careful to band limit the input signal to avoid aliasing high frequency components and noise into the passband.

The track-and-hold amplifier is internally controlled by the Start command and is not directly available to the user. After the Start command signal the track-and-hold is placed into the hold mode; it returns to the track mode after the conversion is complete.

CLOCK

The AD8401 uses an external clock that is TTL or 5 V CMOS compatible. The external clock speed is 5 MHz and the duty cycle may vary from 30% to 70%. The external clock can be continuously operated between conversions.

DIGITAL INTERFACE: ADC TIMING AND CONTROL

Two basic ADC operating modes are available with the AD8401. The first mode uses the Start ($\overline{ST}$) pin to trigger a synchronized A/D conversion. As soon as the $\overline{ST}$ pin is asserted, the T/H switches from tracking to the hold mode capturing the present analog input-voltage sample. With the T/H holding the analog sample the successive-approximation analog-to-digital conversion is completed on that sample value. At the end of conversion the T/H returns to the tracking mode. This mode of conversion is ideal for digital signal processing applications where precise interval sampling is necessary to minimize errors due to sampling uncertainty or jitter. A precise clock source can be used to drive the $\overline{ST}$ input.

The second mode of conversion is started by the $\overline{RD}$ and $\overline{CS}$ inputs going low, after which the $\overline{BUSY}$ line puts the microprocessor into a WAIT state until end of conversion. Mode 2 is asserted by connecting the $\overline{ST}$ pin to logic high. The major advantage of this interface is that a single Read Instruction will start and complete a new analog-to-digital conversion without the need for carefully tailored software delays that often are not portable when software routines are taken to a different processor running at a different clock speed.

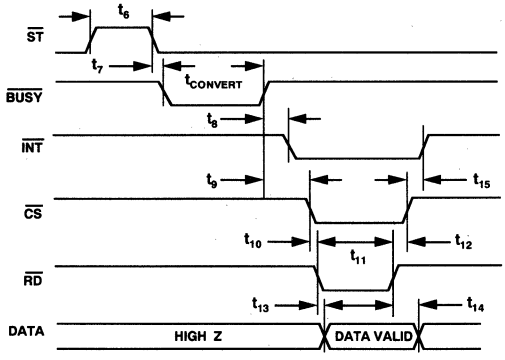

Figure 6. Mode 1, ADC Interface Timing

Mode 1 Interface

As shown in Figure 6, the falling edge of the $\overline{ST}$ pulse initiates a conversion and puts the T/H amplifier into the hold mode. The $\overline{BUSY}$ signal goes low during the whole A/D conversion time and returns high signaling end of conversion. The $\overline{INT}$ line can be used to interrupt the microprocessor. When the microprocessor performs a READ to access the AD8401 data, the rising edges of $\overline{CS}$ or $\overline{RD}$ will reset the $\overline{INT}$ output to high after the t_{15} timing specification. $\overline{INT}$ can also be used to externally trigger a pulse that activates the $\overline{CS}$ and $\overline{RD}$ and places the new data into a buffer or First In First Out FIFO memory. The microprocessor can then load a series of readings from this buffer memory at a convenient time. Care must be taken not to have the $\overline{ST}$ input high when $\overline{RD}$ is brought low; otherwise, the AD8401 will not operate properly. Also triggering the $\overline{ST}$ line a second time before conversion is complete will cause erroneous readings.

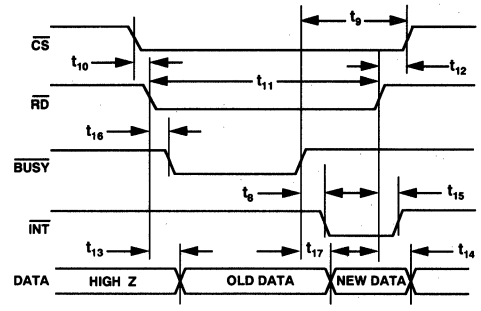

Figure 7. Mode 2, ADC Interface Timing

Mode 2 Interface

This interface mode can be used with microprocessors that can be put into a WAIT state for at least 2 microseconds. The $\overline{ST}$ pin must be tied to logic high for proper operation. The microprocessor begins a conversion by executing a READ instruction that asserts the $\overline{CS}$ and $\overline{RD}$ pins at the AD8401's decoded address. The AD8401 $\overline{BUSY}$ output then goes low, forcing the microprocessor's READY (or WAIT) line into a WAIT state. The analog input signal is captured by the T/H on the falling edge of $\overline{RD}$. When the conversion is complete (8 clocks later), the $\overline{BUSY}$ line returns high, and then the µP completes its READ of the new data now on the digital output port of the AD8401. Note that while conversion is in progress the ADC places the results from the last conversion (Old Data) on the data bus. The Figure 7 timing diagram details the applicable timing specification requirements.

DIGITAL INTERFACE: DAC TIMING AND CONTROL

Table II shows the truth table for DAC operation. The internal 8-bit DAC register contents are loaded from the data bus when both $\overline{WR}$ and $\overline{CS}$ are asserted. The DAC register determines the D/A converter analog-output voltage. The $\overline{WR}$ input is a positive edge triggered input that loads the bus data into the DAC register subject to the data setup and data hold timing requirements. When $\overline{CS}$ and $\overline{WR}$ are low, the DAC register contents will not change with changing data bus values. Figure 8 provides the detail timing diagram for write cycle operation.

Table II. DAC Register Logic

$\overline{CS}$	$\overline{WR}$	$\overline{RS}$	DAC Function
H	H	H	No Effect
L	L	H	No Effect
L	∧	H	DAC Register Updated
∧	L	H	DAC Register Updated
X	X	L	DAC Register Loaded with all Zeros

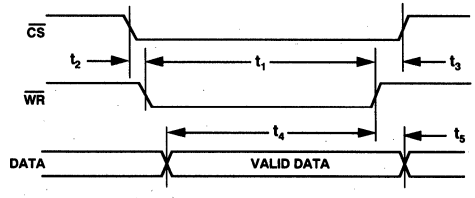

Figure 8. Write Cycle Timing

An active low pulse, at any time, on the RESET pin asynchronously forces all DAC register bits to zero. The DAC output voltage becomes zero volts and stays at that value until a new data word is loaded into the DAC register with a new $\overline{WR}$ command. The equivalent input logic for the DAC register loading is shown in Figure 9.

APPLICATIONS INFORMATION

The software programming needs to format data as defined by the transfer equations and Code Tables that follow.

DAC Transfer Equation

$$V_{OUT} = 2.500 \times \frac{D}{256} = 2.500 \times \frac{255}{256}$$ for a 2.50 V full scale

where D is the decimal value 0 through 255 of the 8-bit data word.

Table III. DAC Unipolar Code

DAC Register Contents		General Transfer Equation	Nominal Analog Output V_{OUT}
Decimal	Binary		
255	1111 1111	$2.500 \times \frac{255}{256}$	2.490 V
129	1000 0001	$2.500 \times \frac{129}{256}$	1.260
128	1000 0000	$2.500 \times \frac{128}{256}$	1.250
127	0111 1111	$2.500 \times \frac{127}{256}$	1.240
1	0000 0001	$2.500 \times \frac{1}{256}$	0.010
0	0000 0000	$2.500 \times \frac{0}{256}$	0.000

The nominal output voltages listed in the Code Table are subject to the static performance specifications. The INL, Zero-Scale and Full-Scale errors describe the total specified variation that will be encountered from part to part. One LSB of error for the 2.5 V FS range is 9.766 millivolts (= 2.50/256).

Although separate AGNDs exist for both the DAC and ADC to minimize crosstalk, writing data to the DAC while the ADC is performing a conversion may result in an incorrect conversion from the ADC due to signal interaction between the DAC and ADC. Therefore, to ensure correct operation of the ADC, the DAC register should not be updated while the ADC is converting.

The AD8401 is configured for an input range of +3.0 volts Full Scale. The nominal transfer characteristic for this range is plotted in Figure 23. The output coding is natural binary with one LSB equal to 11.72 millivolts. Note that the first code transition between 0 and 1 LSB occurs at 5.8 mV, one half of the 11.72 mV LSB step size. The last code transition occurs at Full Scale minus 1.5 LSBs, which is a 2.982 V input.

The AD8401 is easily interfaced to most microprocessors by using either address bits or address decode to select the appropriate multiplexer channel. Figure 24 shows how easily the AD8401 interfaces to the AD899. No additional hardware is required.

ANALOG DEVICES

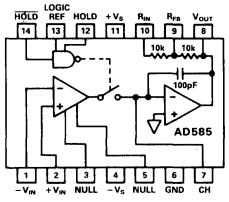
High Speed, Precision Sample-and-Hold Amplifier

AD585

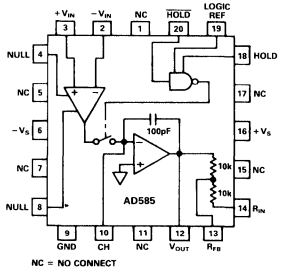
FEATURES
3.0μs Acquisition Time to ±0.01% max
Low Droop Rate: 1.0mV/ms max
Sample/Hold Offset Step: 3mV max
Aperture Jitter: 0.5ns
Extended Temperature Range: −55°C to +125°C
Internal Hold Capacitor
Internal Application Resistors
±12V or ±15V Operation
Available in Surface Mount

APPLICATIONS
Data Acquisition Systems
Data Distribution Systems
Analog Delay & Storage
Peak Amplitude Measurements
MIL-STD-883 Compliant Versions Available

DIP



LCC/PLCC PACKAGE



NC = NO CONNECT

6

PRODUCT DESCRIPTION

The AD585 is a complete monolithic sample-and-hold circuit consisting of a high performance operational amplifier in series with an ultralow leakage analog switch and a FET input integrating amplifier. An internal holding capacitor and matched applications resistors have been provided for high precision and applications flexibility.

The performance of the AD585 makes it ideal for high speed 10- and 12-bit data acquisition systems, where fast acquisition time, low sample-to-hold offset, and low droop are critical. The AD585 can acquire a signal to ±0.01% in 3μs maximum, and then hold that signal with a maximum sample-to-hold offset of 3mV and less than 1mV/ms droop, using the on-chip hold capacitor. If lower droop is required, it is possible to add a larger external hold capacitor.

The high-speed analog switch used in the AD585 exhibits aperture jitter of 0.5ns, enabling the device to sample full-scale (20V peak-to-peak) signals at frequencies up to 78kHz with 12-bit precision.

The AD585 can be used with any user-defined feedback network to provide any desired gain in the sample mode. On-chip precision thin-film resistors can be used to provide gains of +1, −1, or +2. Output impedance in the hold mode is sufficiently low to maintain an accurate output signal even when driving the dynamic load presented by a successive-approximation A/D converter. However, the output is protected against damage from accidental short circuits.

The control signal for the HOLD command can be either active high or active low. The differential HOLD signal is compatible with all logic families, if a suitable reference level is provided. An on-chip TTL reference level is provided for TTL compatibility.

The AD585 is available in three performance grades. The JP grade is specified for the 0 to +70°C commercial temperature range and packaged in a 20-pin PLCC. The AQ grade is specified for the −25°C to +85°C industrial temperature range and is packaged in a 14-pin cerdip. The SQ and SE grades are specified for the −55°C to +125°C military temperature range and are packaged in a 14-pin cerdip and 20-pin LCC.

PRODUCT HIGHLIGHTS

1. The fast acquisition time (3μs) and low aperture jitter (0.5ns) make it the first choice for very high speed data acquisition systems.
2. The droop rate is only 1.0mV/ms so that it may be used in slower high accuracy systems without the loss of accuracy.
3. The low charge transfer of the analog switch keeps sample-to-hold offset below 3mV with the on-chip 100pF hold capacitor, eliminating the trade-off between acquisition time and S/H offset required with other SHAs.
4. The AD585 has internal pretrimmed application resistors for applications versatility.
5. The AD585 is complete with an internal hold capacitor for ease of use. Capacitance can be added externally to reduce the droop rate when long hold times and high accuracy are required.
6. The AD585 is recommended for use with 10- and 12-bit successive-approximation A/D converters such as AD573, AD574A, AD674A, AD7572 and AD7672.
7. The AD585 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD585/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

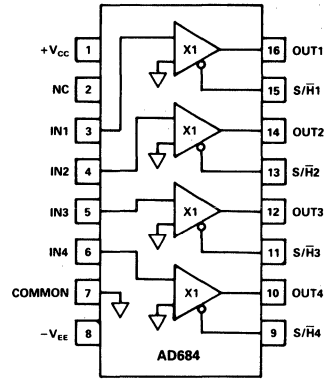
FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD684 is a monolithic quad sample-and-hold amplifier (SHA). It features four complete sampling channels, each controlled by an independent hold command. Each SHA is complete with an internal hold capacitor. The high accuracy SHA channels are self-contained and require no external components or adjustments. The AD684 is manufactured on a BiMOS process which provides a merger of high performance bipolar circuitry and low power CMOS logic.

The AD684 is ideal for high performance, multichannel data acquisition systems. Each SHA channel can acquire a signal in less than 1μs and retain the held value with a droop rate of less than 0.01μV/μs. Excellent linearity and ac performance make the AD684 an ideal front end for high speed 12- and 14-bit ADCs.

The AD684 has a self-correcting architecture that minimizes hold mode errors and insures accuracy over temperature. Each channel of the AD684 is capable of sourcing 5mA and incorporates output short circuit protection.

The AD684 is specified for three temperature ranges. The J grade device is specified for operation from 0 to 70°C, the A grade from −40°C to +85°C and the S grade from −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. Fast acquisition time (1μs) and low aperture jitter (75ps) make the AD684 the best choice for multiple channel data acquisition systems.
2. Monolithic construction insures excellent interchannel matching in terms of timing and accuracy, as well as high reliability.
3. Independent inputs, outputs and sample-and-hold controls allow user flexibility in system architecture.
4. Low droop (0.01μV/μs) and internally compensated hold mode error results in superior system accuracy.
5. The AD684's fast settling time and low output impedance make it ideal for driving high speed analog to digital converters such as the AD578, AD674, AD7572 and the AD7672.
6. The AD684 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD684/883B data sheet for detailed specifications.

PRODUCT DESCRIPTION

The AD781 is a high speed monolithic sample-and-hold amplifier (SHA). The AD781 guarantees a maximum acquisition time of 700 ns to 0.01% over temperature. The AD781 is specified and tested for hold mode total harmonic distortion and hold mode signal-to-noise and distortion. The AD781 is configured as a unity gain amplifier and uses a self-correcting architecture that minimizes hold mode errors and insures accuracy over temperature. The AD781 is self-contained and requires no external components or adjustments.

The low power dissipation, 8-pin mini-DIP package and completeness make the AD781 ideal for highly compact board layouts. The AD781 will acquire a full-scale input in less than 700 ns and retain the held value with a droop rate of 0.01 μV/μs. Excellent linearity and hold mode dc and dynamic performance make the AD781 ideal for 12- and 14-bit high speed analog-to-digital converters.

The AD781 is manufactured on Analog Devices' BiMOS process which merges high performance, low noise bipolar circuitry with low power CMOS to provide an accurate, high speed, low power SHA.

The AD781 is specified for three temperature ranges. The J grade device is specified for operation from 0°C to 70°C, the A grade from −40°C to +85°C and the S grade from −55°C to +125°C. The J and A grades are available in 8-pin plastic DIP packages. The S grade is available in an 8-pin cerdip package.

PRODUCT HIGHLIGHTS

1. Fast acquisition time (700 ns), low aperture jitter (75 ps) and fully specified hold mode distortion make the AD781 an ideal SHA for sampling systems.
2. Low droop (0.01 μV/μs) and internally compensated hold mode error results in superior system accuracy.
3. Low power (95 mW typical), complete functionality and small size make the AD781 an ideal choice for a variety of high performance, low power applications.
4. The AD781 requires no external components or adjustments.
5. Excellent choice as a front-end SHA for high speed analog-to-digital converters such as the AD671, AD7586, AD674B, AD774B, AD7572 and AD7672.
6. Fully specified and tested hold mode distortion guarantees the performance of the SHA in sampled data systems.
7. The AD781 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD781/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.

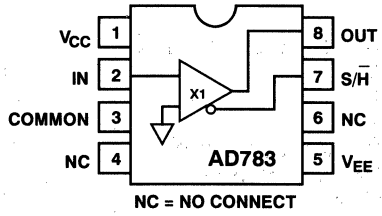
Complete Very High Speed Sample-and-Hold Amplifier

AD783*

FEATURES

Acquisition Time to 0.01%: 250 ns Typical
Low Power Dissipation: 95 mW
Low Droop Rate: 0.02 μV/μs
Fully Specified and Tested Hold Mode Distortion
Total Harmonic Distortion: −85 dB
Aperture Jitter: 50 ps Maximum
Internal Hold Capacitor
Self-Correcting Architecture
8-Pin Mini Cerdip and SOIC Packages

FUNCTIONAL BLOCK DIAGRAM



NC = NO CONNECT

PRODUCT DESCRIPTION

The AD783 is a high speed, monolithic sample-and-hold amplifier (SHA). The AD783 offers a typical acquisition time of 250 ns to 0.01%. The AD783 is specified and tested for hold mode total harmonic distortion with input frequencies up to 100 kHz. The AD783 is configured as a unity gain amplifier and uses a patented self-correcting architecture that minimizes hold mode errors and ensures accuracy over temperature. The AD783 is self-contained and requires no external components or adjustments.

The AD783 retains the held value with a droop rate of 0.02 μV/μs. Excellent linearity and hold mode dc and dynamic performance make the AD783 ideal for high speed 12- and 14-bit analog-to-digital converters.

The AD783 is manufactured on Analog Devices' ABCMOS process which merges high performance, low noise bipolar circuitry with low power CMOS to provide an accurate, high speed, low power SHA.

The J grade device is specified for operation from 0°C to +70°C and the A grade from −40°C to +85°C. The J and A grades are available in 8-pin cerdip and SOIC packages. The military temperature range version is specified for operation from −55°C to +125°C and is available in an 8-pin cerdip package. For details refer to the *Analog Devices Military Products Databook* or AD783/883B data sheet.

***Protected by U.S. Patent Number 4,962,325.**

PRODUCT HIGHLIGHTS

1. Fast acquisition time (250 ns), low aperture jitter (20 ps) and fully specified hold mode distortion make the AD783 an ideal SHA for sampling systems.
2. Low droop (0.02 μV/μs) and internally compensated hold mode error result in superior system accuracy.
3. Low power (95 mW typical), complete functionality and small size make the AD783 an ideal choice for a variety of high performance applications.
4. The AD783 requires no external components or adjustments.
5. The AD783 is an excellent choice as a front-end SHA for high speed analog-to-digital converters such as the AD671, AD7586, AD674B, AD774B, AD7572 and AD7672.
6. Fully specified and tested hold mode distortion guarantees the performance of the SHA in sampled data systems.

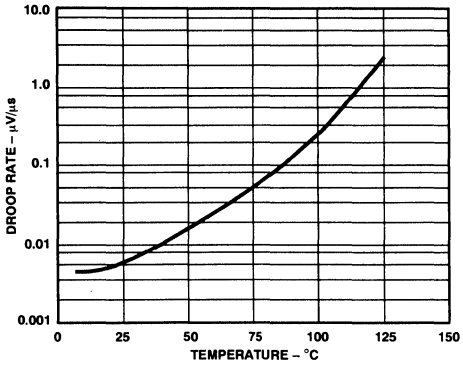
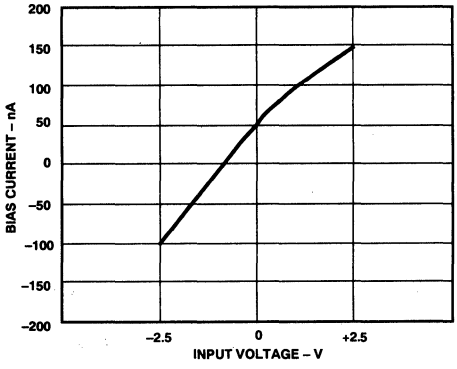
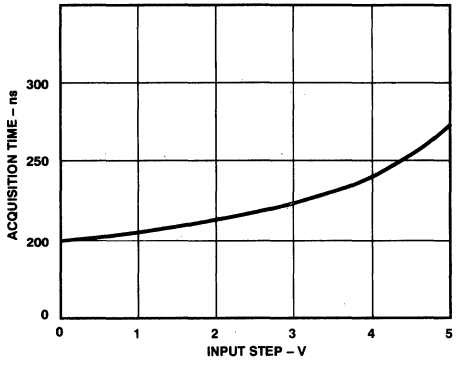
Power Supply Rejection Ratio vs. Frequency



Droop Rate vs. Temperature, V_{IN} = 0 V



Bias Current vs. Input Voltage



Acquisition Time (to 0.01%) vs. Input Step Size

DEFINITIONS OF SPECIFICATIONS

Acquisition Time—The length of time that the SHA must remain in the sample mode in order to acquire a full-scale input step to a given level of accuracy.

Small Signal Bandwidth—The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 100 mV p–p sine wave.

Full Power Bandwidth—The frequency at which the held output amplitude is 3 dB below the input amplitude, under an input condition of a 5 V p–p sine wave.

Effective Aperture Delay—The difference between the switch delay and the analog delay of the SHA channel. A negative number indicates that the analog portion of the overall delay is greater than the switch portion. This effective delay represents the point in time, relative to the hold command, that the input signal will be sampled.

Aperture Jitter—The variations in aperture delay for successive samples. Aperture jitter puts an upper limit on the maximum frequency that can be accurately sampled.

Hold Settling Time—The time required for the output to settle to within a specified level of accuracy of its final held value after the hold command has been given.

Droop Rate—The drift in output voltage while in the hold mode.

Feedthrough—The attenuated version of a changing input signal that appears at the output when the SHA is in the hold mode.

Hold Mode Offset—The difference between the input signal and the held output. This offset term applies only in the hold mode and includes the error caused by charge injection and all other internal offsets. It is specified for an input of 0 V.

Sample Mode Offset—The difference between the input and output signals when the SHA is in the sample mode.

Nonlinearity—The deviation from a straight line on a plot of input vs. (held) output as referenced to a straight line drawn between endpoints, over an input range of −2.5 V and +2.5 V.

Gain Error—Deviation from a gain of +1 on the transfer function of input vs. held output.

Power Supply Rejection Ratio—A measure of change in the held output voltage for a specified change in the positive or negative supply.

Sampled DC Uncertainty—The internal rms SHA noise that is sampled onto the hold capacitor.

Hold Mode Noise—The rms noise at the output of the SHA while in the hold mode, specified over a given bandwidth.

Total Output Noise—The total rms noise that is seen at the output of the SHA while in the hold mode. It is the rms summation of the sampled dc uncertainty and the hold mode noise.

Output Drive Current—The maximum current the SHA can source (or sink) while maintaining a change in hold mode offset of less than 2.5 mV.

Signal-To-Noise and Distortion (S/N+D) Ratio—S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

Total Harmonic Distortion (THD)—THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed in decibels.

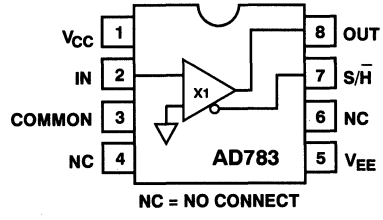
Intermodulation Distortion (IMD)—With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequency of mfa±nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa+fb) and (fa−fb), and the third order terms are (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude, and peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

FUNCTIONAL DESCRIPTION

The AD783 is a complete, high speed sample-and-hold amplifier that provides high speed sampling to 12-bit accuracy in 250 ns.

The AD783 is completely self-contained, including an on-chip hold capacitor, and requires no external components or adjustments to perform the sampling function. Both input and output are treated as a single-ended signal, referred to common.

The AD783 utilizes a proprietary circuit design which includes a self-correcting architecture. This sample-and-hold circuit corrects for internal errors after the hold command has been given, by compensating for amplifier gain and offset errors, and charge injection errors. Due to the nature of the design, the SHA output in the sample mode is not intended to provide an accurate representation of the input. However, in hold mode, the internal circuitry is reconfigured to produce an accurately held version of the input signal. Below is a block diagram of the AD783.



Functional Block Diagram

DYNAMIC PERFORMANCE

The AD783 is compatible with 12-bit A-to-D converters in terms of both accuracy and speed. The fast acquisition time, fast hold settling time and good output drive capability allow the AD783 to be used with high speed, high resolution A-to-D converters like the AD671 and AD7586. The AD783's fast acquisition time provides high throughput rates for multichannel data acquisition systems. Typically, the AD783 can acquire a 5 V step in less than 250 ns. Figure 1 shows the settling accuracy as a function of acquisition time.

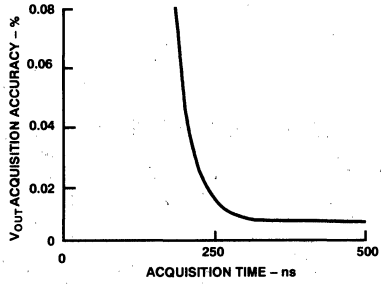


Figure 1. V_{OUT} Settling vs. Acquisition Time

The hold settling determines the required time, after the hold command is given, for the output to settle to its final specified accuracy. The typical settling behavior of the AD783 is 150 ns. The settling time of the AD783 is sufficiently fast to allow the SHA, in most cases, to directly drive an A-to-D converter without the need for an added "start convert" delay.

HOLD MODE OFFSET

The dc accuracy of the AD783 is determined primarily by the hold mode offset. The hold mode offset refers to the difference between the final held output voltage and the input signal at the time the hold command is given. The hold mode offset arises from a voltage error introduced onto the hold capacitor by charge injection of the internal switches. The nominal hold mode offset is specified for a 0 V input condition. Over the input range of −2.5 V to +2.5 V, the AD783 is also characterized for an effective gain error and nonlinearity of the held value, as shown in Figure 2. As indicated by the AD783 specifications, the hold mode offset is very stable over temperature.

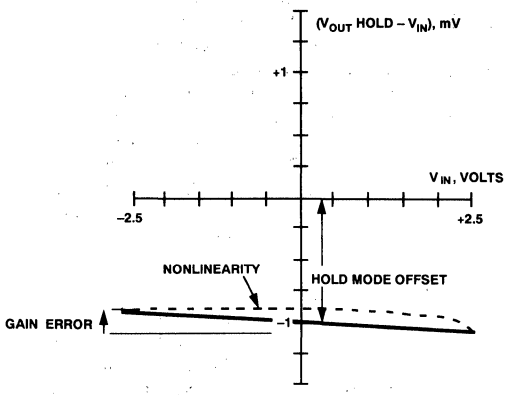

Figure 2. Hold Mode Offset, Gain Error and Nonlinearity

For applications where it is important to obtain zero offset, the hold mode offset may be nulled externally at the input to the A-to-D converter. Adjustment of the offset may be accomplished through the A-to-D itself or by an external amplifier with offset nulling capability (e.g., AD711). The offset will change less than 0.5 mV over the specified temperature range.

SUPPLY DECOUPLING AND GROUNDING CONSIDERATIONS

As with any high speed, high resolution data acquisition system, the power supplies should be well regulated and free from excessive high frequency noise (ripple). The supply connection to the AD783 should also be capable of delivering transient currents to the device. To achieve the specified accuracy and dynamic performance, decoupling capacitors must be placed directly at both the positive and negative supply pins to common. Ceramic type 0.1 μF capacitors should be connected from V_{CC} and V_{EE} to common.

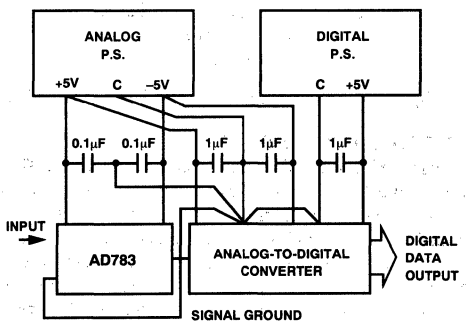

Figure 3. Basic Grounding and Decoupling Diagram

The AD783 does not provide separate analog and digital ground leads as is the case with most A-to-D converters. The common pin is the single ground terminal for the device. It is the reference point for the sampled input voltage and the held output voltage and also the digital ground return path. The common pin should be connected to the reference (analog) ground of the A-to-D converter with a separate ground lead. Since the analog and digital grounds in the AD783 are connected internally, the common pin should also be connected to the digital ground, which is usually tied to analog common at the A-to-D converter. Figure 3 illustrates the recommended decoupling and grounding practice.

NOISE CHARACTERISTICS

Designers of data conversion circuits must also consider the effect of noise sources on the accuracy of the data acquisition system. A sample-and-hold amplifier that precedes the A-to-D converter introduces some noise and represents another source of uncertainty in the conversion process. The noise from the AD783 is specified as the total output noise, which includes both the sampled wideband noise of the SHA in addition to the band limited output noise. The total output noise is the rms sum of the sampled dc uncertainty and the hold mode noise. A plot of the total output noise vs. the equivalent input bandwidth of the converter being used is given in Figure 4.

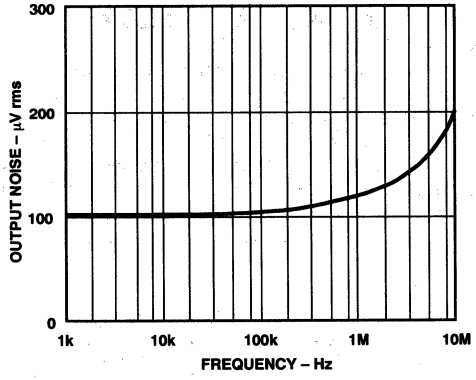

Figure 4. RMS Noise vs. Input Bandwidth of ADC

DRIVING THE ANALOG INPUTS

For best performance, it is important to drive the AD783 analog input from a low impedance signal source. This enhances the sampling accuracy by minimizing the analog and digital crosstalk. Signals which come from higher impedance sources (e.g., over 5 kΩ) will have a relatively higher level of crosstalk. For applications where signals have high source impedance, an operational amplifier buffer in front of the AD783 is required. The AD711 (precision BiFET op amp) is recommended for these applications.

HIGH FREQUENCY SAMPLING

Aperture jitter and distortion are the primary factors which limit frequency domain performance of a sample-and-hold amplifier. Aperture jitter modulates the phase of the hold command and produces an effective noise on the sampled analog input. The magnitude of the jitter induced noise is directly related to the frequency of the input signal.

A graph showing the magnitude of the jitter induced error vs. frequency of the input signal is given in Figure 5.

The accuracy in sampling high frequency signals is also constrained by the distortion and noise created by the sample-and-hold. The level of distortion increases with frequency and reduces the "effective number of bits" of the conversion.

Measurements of Figures 6 and 7 were made using a 14-bit A/D converter with V_{IN} = 5 V p–p and a sample frequency of 100 ksps.

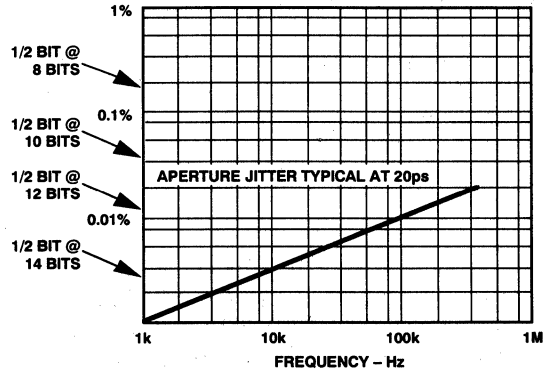

Figure 5. Error Magnitude vs. Frequency

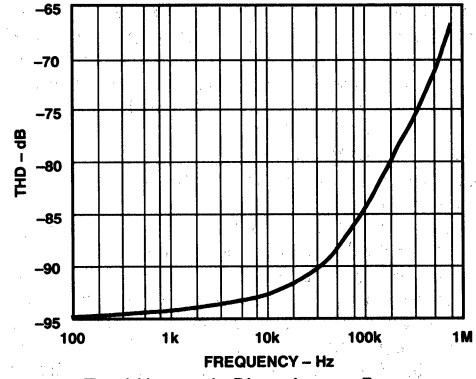

Figure 6. Total Harmonic Distortion vs. Frequency

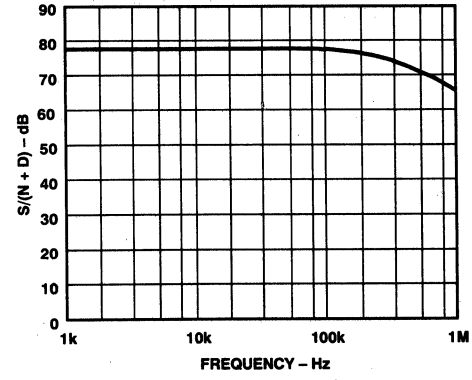

Figure 7. Signal/(Noise and Distortion) vs. Frequency

AD783 TO AD670 INTERFACE

The 15 MHz small signal bandwidth of the AD783 makes it a good choice for undersampling applications. Figure 8 shows the interface between the AD783 and the AD670 ADC, where the AD783 samples the incoming IF signal. For this particular application, the IF carrier was 10.7 MHz and the information signal was a 5 kHz FSK-modulated tone. The sample-and-hold signal is applied to the 8-bit AD670 ADC and then digitally processed for analysis.

The CLKIN signal is connected directly to the S/H pin of the AD783 and must comply with the acquisition and settling requirements of the SHA. A delayed version of CLKIN is applied to the R/$\overline{W}$ input of the AD670 in order to accommodate the hold-mode settling requirements of the AD783. The 10 μs conversion speed of the AD670 combined with the 150 ns hold-mode settling time of the AD783 result in a total system throughput of 10.15 μs.

By keeping the 10.7 MHz IF input to the AD783 at a low amplitude, 255 mV p-p, the resultant distortion and jitter-induced noise result in approximately 45 dB of dynamic range. The AD670 can be conveniently configured such that its full-scale input range is 255 mV in order to retain the full 8-bit dynamic range of the converter. The maximum sample rate of the AD670 is 10 μs; therefore, to comply with the Nyquist criteria the maximum information bandwidth is 50 kHz.

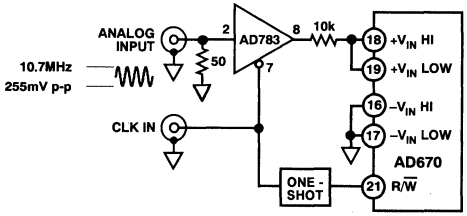

Figure 8. AD783 to AD670 Interface

AD783 to AD671 (12-Bit, 500 ns ADC) Interface

The AD783 to AD671 interface requires an op amp, a dual flip-flop, and a monostable multivibrator or "one-shot." The op amp amplifies the ±2.5 V output of the AD783 to the full-scale input of the AD671. Appropriate op amps include the AD841 and AD845 (see the AD671 data sheet for additional information). The flip-flops and one-shot are used to generate the AD671 ENCODE pulse and the appropriately timed AD783 S/H pulse.

A master sampling clock is tied to the clock input of flip-flop1 and the input of the one-shot. The D1 input of flip-flop1 should be tied high and the one-shot should be configured to generate a pulse on a rising edge of the sampling clock. The rising edge of the sampling clock causes the $\overline{Q1}$ output of the flip-flop to go low placing the AD783 into hold mode. Simultaneously, a low going pulse is generated at the one-shot output. The length of this pulse would usually be made long enough to allow the output of the AD783 to settle (hold-mode settling time), but because of the error-correcting ability of the AD671, the length of this pulse may be reduced to approximately 200 ns.

The low-going one-shot output is connected to the clock input of flip-flop2. The D2 input of flip-flop2 is tied high. The rising edge of the low-going pulse toggles the Q2 output of flip-flop2 to a high state. This output, which is tied to the ENCODE input of the AD671, initiates a conversion of the buffered output signal of the AD783. The AD671 issues the signal DAV when the conversion is complete. The DAV signal is tied to the asynchronous $\overline{CLR1}$ and $\overline{CLR2}$ inputs of both flip-flops. When DAV goes low, the $\overline{Q1}$ output goes high returning the AD783 to the sample or acquisition mode. The Q2 output (ENCODE) returns low until it is again triggered by the rising edge of the one-shot output.

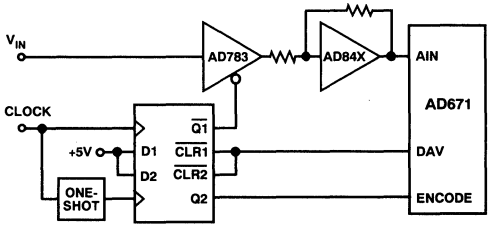

Figure 9. AD783 to AD671 Interface

Ultrahigh Speed Monolithic Track-and-Hold

AD9100*

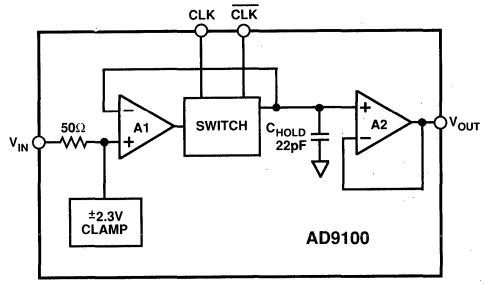
FEATURES

Excellent Hold Mode Distortion into 250 Ω
−88 dB @ 30 MSPS (2.3 MHz V_{IN})
−83 dB @ 30 MSPS (12.1 MHz V_{IN})
−74 dB @ 30 MSPS (19.7 MHz V_{IN})
16 ns Acquisition Time to 0.01%
<1 ps Aperture Jitter
250 MHz Tracking Bandwidth
83 dB Feedthrough Rejection @ 20 MHz
3.3 nV/$\sqrt{Hz}$ Spectral Noise Density
MIL-STD-Compliant Versions Available

APPLICATIONS

A/D Conversion
Direct IF Sampling
Imaging/FLIR Systems
Peak Detectors
Radar/EW/ECM
Spectrum Analysis
CCD ATE

BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9100 is a monolithic track-and-hold amplifier which sets a new standard for high speed and high dynamic range applications. It is fabricated in a mature high speed complementary bipolar process. In addition to innovative design topologies, a custom package is utilized to minimize parasitics and optimize dynamic performance.

Acquisition time (hold to track) is 13 ns to 0.1% accuracy, and 16 ns to 0.01%. The AD9100 boasts superlative hold-mode frequency domain performance; when sampling at 30 MSPS hold mode distortion is less than −83 dBfs for analog frequencies up to 12 MHz; and −74 dBfs at 20 MHz. The AD9100 can also drive capacitive loads up to 100 pF with little degradation in acquisition time; it is therefore well suited to drive 8- and 10-bit flash converters at clock speeds to 50 MSPS. With a spectral noise density of 3.3 nV/$\sqrt{Hz}$ and feedthrough rejection of 83 dB at 20 MHz, the AD9100 is well suited to enhance the dynamic range of many 8- to 16-bit systems.

The AD9100 is "user friendly" and easy to apply: (1) it requires +5 V/−5.2 V power supplies; (2) the hold capacitor and switch power supply decoupling capacitors are built into the DIP package; (3) the encode clock is differential ECL to minimize clock jitter; (4) the input resistance is typically 800 kΩ; (5) the analog input is internally clamped to prevent damage from voltage transients.

The AD9100 is available in a 20-lead side-brazed "skinny DIP" package and a 28-lead LCC package. Commercial, industrial, and military temperature grade parts are available. Consult the factory for information about the availability of 883-qualified devices.

PRODUCT HIGHLIGHTS

1. Hold Mode Distortion is guaranteed.
2. Monolithic construction.
3. Analog input is internally clamped to protect against overvoltage transients and ensure fast recovery.
4. Output is short circuit protected.
5. Drives capacitive loads to 100 pF.
6. Differential ECL clock inputs.

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Analog input voltage should not exceed $\pm V_S$.
[3]AD9100JD: 0°C to +70°C. AD9100AD: −40°C to +85°C. AD9100SD: −55°C to +125°C. DIP θ_{JA} = 38°C/W; this is valid with the device mounted flush to a grounded 2 oz copper clad board with 16 sq inches of surface area and no air flow. LCC θ_{JA} = 48°C/W.
[4]The input to the AD9100 is internally clamped at ±2.3 V. The internal input series resistance is nominally 50 Ω.
[5]Hold mode noise is proportional to the length of time a signal is held. For example, if the hold time (t_H) is 20 ns, the accumulated noise is typically 6 μV (300 V/s × 20 ns). This value must be combined with the track mode noise to obtain total noise.
[6]Min and max droop rates are based on the military temperature range (−55°C to +125°C). Refer to the "Droop Rate vs Temperature" chart for min/max limits over the commercial and industrial ranges.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level

125 MSPS Monolithic Sampling Amplifier

AD9101

FEATURES
350 MHz Sampling Bandwidth
125 MHz Sampling Rate
Excellent Hold Mode Distortion
−75 dB @ 50 MSPS (25 MHz V_{IN})
−57 dB @ 125 MSPS (50 MHz V_{IN})
7 ns Acquisition Time to 0.1%
<1 ps Aperture Jitter
66 dB Feedthrough Rejection @ 50 MHz
3.3 nV/$\sqrt{Hz}$ Spectral Noise Density

APPLICATIONS
Direct IF Sampling
Digital Sampling Oscilloscopes
HDTV Cameras
Peak Detectors
Radar/EW/ECM
Spectrum Analysis
Test Equipment/CCD Testers
DDS DAC Deglitcher

GENERAL DESCRIPTION

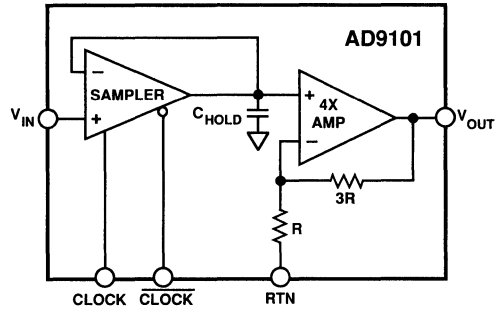
The AD9101 is an extremely accurate, general purpose, high speed sampling amplifier. Its fast and accurate acquisition speed allows for a wide range of frequency vs. resolution performance. The AD9101 is capable of 8 to 12 bits of accuracy at clock rates of 125 MSPS or 50 MSPS, respectively. This level of performance makes it an ideal driver for almost all 8- to 12-bit A/D encoders on the market today.

In effect, the AD9101 is a track-and-hold with a post amplifier. This configuration allows the front end sampler to operate at relatively low signal amplitudes. This results in dramatic improvement in both track and hold mode distortion while keeping power low.

The gain-of-four output amplifier has been optimized for fast and accurate large signal step settling characteristics even when heavily loaded. This amplifier's fast Settling Time Linearity (STL) characteristic causes the amplifier to be transparent to the low signal level distortion of the sampler. When sampled, output distortion levels reflect only the distortion performance of the sampler.

Dramatic SNR and distortion improvements can be realized when using the AD9101 with high speed flash converters. Flash converters generally have excellent linearity at dc and low frequencies. However, as signal slew rate increases, their performance degrades due to the internal comparators' aperture delay variations and finite gain bandwidth product.

FUNCTIONAL BLOCK DIAGRAM



The benefits of using a track-and-hold ahead of a flash converter have been well known for many years. However, before the AD9101, there was no track-and-hold amplifier with sufficient bandwidth and linearity to markedly increase the dynamic performance of such flashes as the AD9002, AD9012, AD9020, and AD9060.

A new application made possible by the AD9101 is direct IF-to-digital conversion. Utilizing the Nyquist principle, the IF frequency can be rejected, and the baseband signal can be recovered. As an example, a 40 MHz IF is modulated by a 10 MHz bandwidth signal. By sampling at 25 MSPS, the signal of interest is detected.

The AD9101 is offered in commercial and military temperature ranges. Commercial versions include the AD9101AR in plastic SOIC and AD9101AE in ceramic LCC. Military devices are available in ceramic LCC. Contact the factory for availability of versions in DIP and/or military versions.

PRODUCT HIGHLIGHTS

1. Guaranteed Hold-Mode Distortion
2. 125 MHz Sampling Rate to 8 Bits; 50 MHz to 12 Bits
3. 350 MHz Sampling Bandwidth
4. Super-Nyquist Sampling Capability
5. Output Offset Adjustable

NOTES
[1]If the analog input exceeds ±300 mV, the clock levels should be shifted as shown in the Theory of Operation section entitled "Driving the Encode Clock."
[2]Time to recover within rated error band from 160% overdrive.
[3]Sampling bandwidth is defined as the −3 dB frequency response of the input sampler to the hold capacitor when operating in the sampling mode. It is greater than tracking bandwidth because it does not include the bandwidth of the output amplifier.
[4]Hold mode noise is proportional to the length of time a signal is held. For example, if the hold time (t_H) is 20 ns, the accumulated noise is typically 3 μV (150 mV/s × 20 ns). This value must be combined with the track mode noise to obtain total noise.
[5]Total energy of worst case track-to-hold or hold-to-track glitch.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

Supply Voltage ($+V_S$) . . . . . −0.5 V to +6 V
Supply Voltage ($-V_S$) . . . . . −6 V to +0.5 V
Analog Input Voltage . . . . . ±5 V
CLOCK/$\overline{\text{CLOCK}}$ Input . . . . . −5 V to +0.5 V
Continuous Output Current[4] . . . . . 70 mA
Storage Temperature . . . . . −65°C to +150°C
Operating Temperature Range
AE, AR . . . . . −40°C to +85°C
SE . . . . . −55°C to +125°C
Junction Temperature (Ceramic)[2] . . . . . +175°C
Junction Temperature (Plastic)[2] . . . . . +150°C
Soldering Temperature (1 minute)[3] . . . . . +220°C

NOTES
[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.
[2]Typical thermal impedances (no air flow, soldered to PC board) are as follows: Ceramic LCC: θ_{JA} = 48°C/W; θ_{JC} = 9.9°C/W; Plastic SOIC: θ_{JA} = 54°C/W; θ_{JC} = 7.3°C/W.
[3]For surface mount devices, mounted by vapor phase soldering. Prior to vapor phase soldering, plastic units should receive a minimum eight hour bakeout at 110°C to drive off any moisture absorbed in plastic during shipping or storage. Through-hole devices can be soldered at +300°C for 10 seconds.
[4]Output is short circuit protected to ground. Continuous short circuit may affect device reliability.

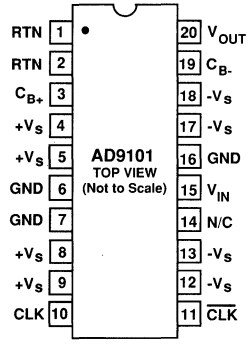
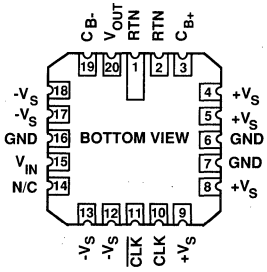
PIN CONFIGURATIONS

20-Pin SOIC



20-PIN LCC PACKAGE (E-20A)



CMOS Quad Sample-and-Hold Amplifier

SMP04

FEATURES

- Four Independent Sample-and-Holds
- Internal Hold Capacitors
- High Accuracy – 12-Bit
- Very Low Droop Rate (2mV/s Typ)
- Output Buffers Stable for $C_L \leq 500pF$
- TTL/CMOS Compatible Logic Inputs
- Single or Dual Supply Applications
- Monolithic Low Power CMOS Design

APPLICATIONS

- Signal Processing Systems
- Multichannel Data Acquisition Systems
- Automatic Test Equipment
- Medical and Analytical Instrumentation
- Event Analysis
- DAC Deglitching

GENERAL DESCRIPTION

The SMP-04 is a monolithic quad sample-and-hold; it has four internal precision buffer amplifiers and internal hold capacitors. It is manufactured in PMI's advanced oxide isolated CMOS technology to obtain high accuracy, low droop rate and fast acquisition time required by data acquisition and signal processing systems. The device can acquire an 8-bit input signal to ±1/2 LSB in less than seven microseconds. The SMP-04 can operate from single or dual power supplies with TTL/CMOS logic compatibility. Its output swing includes the negative supply.

The SMP-04 is ideally suited for a wide variety of sample-and-hold applications including amplifier offset or VCA gain adjustments. One or more can be used with a single or multiple DACs to provide multiple set points within a system.

The SMP-04 offers significant cost and size reduction over equivalent module or discrete designs. It is available in a 16-pin hermetic or plastic DIP and surface mount SOIC packages. It is specified over the extended industrial temperature range of –40°C to +85°C. See SMP-04/883 data sheet for –55°C to +125°C specifications.

(Not short-circuit protected)
Digital Input Voltage to DGND ..... –0.3V, V_{DD} +0.3V
Operating Temperature Range
EQ, EP, ES ..... –40°C to +85°C
AQ ..... –55°C to +125°C
Junction Temperature ..... +150°C
Storage Temperature ..... –65°C to +150°C
Lead Temperature (Soldering, 60 sec) ..... +300°C

PACKAGE TYPE	Θ_{JA} (Note 1)	Θ_{JC}	UNITS
16-Pin CerDIP (Q)	94	12	°C/W
16-Pin Plastic DIP (P)	76	33	°C/W
16-Pin SO (S)	92	27	°C/W

NOTE:
1. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP and P-DIP packages; Θ_{JA} is specified for device soldered to printed circuit board for SO package.

CAUTION:
1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and function operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper anti-static handling procedures.
3. Remove power before inserting or removing units from their sockets.

Octal Sample-and-Hold with Multiplexed Input

SMP08

FEATURES

- Internal Hold Capacitors
- Low Droop Rate
- TTL/CMOS Compatible Logic Inputs
- Single or Dual Supply Operation
- Break-Before-Make Channel Addressing
- Compatible With CD4051 Pinout
- Low Cost

APPLICATIONS

- Multiple Path Timing Deskew for A.T.E.
- Memory Programmers
- Mass Flow/Process Control Systems
- Multichannel Data Acquisition Systems
- Robotics and Control Systems
- Medical and Analytical Instrumentation
- Event Analysis
- Stage Lighting Control

GENERAL DESCRIPTION

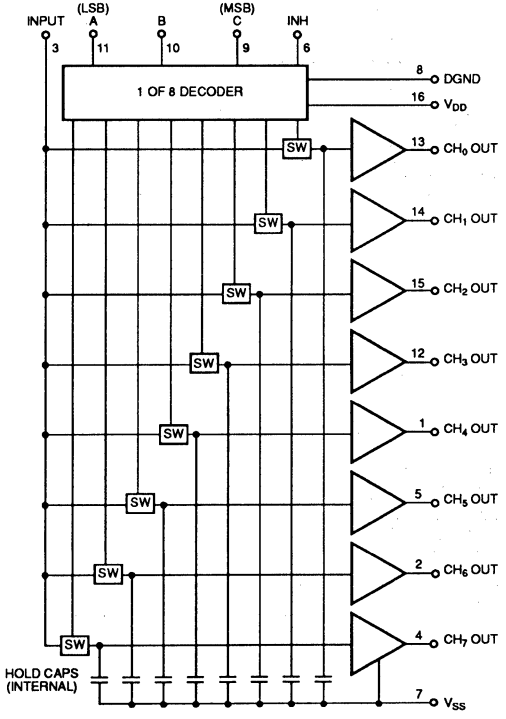
The SMP-08 is a monolithic octal sample-and-hold; it has eight internal buffer amplifiers, input multiplexer, and internal hold capacitors. It is manufactured in an advanced oxide isolated CMOS technology to obtain high accuracy, low droop rate, and fast acquisition time. The SMP-08 has a typical linearity error of only 0.01% and can accurately acquire a 10-bit input signal to ±1/2 LSB in less than seven microseconds. The SMP-08's output swing includes the negative supply in both single and dual supply operation.

The SMP-08 was specifically designed for systems that use a calibration cycle to adjust a multiple of system parameters. The low cost and high level of integration makes the SMP-08 ideal for calibration requirements that have previously required an ASIC, or high cost multiple D/A converters.

The SMP-08 is also ideally suited for a wide variety of sample-and-hold applications including amplifier offset or VCA gain adjustments. One or more SMP-08s can be used with single or multiple DACs to provide multiple set points within a system.

The SMP-08 offers significant cost and size reduction over discrete designs. It is available in a 16-pin hermetic or plastic DIP, or surface mount SOIC package.

FUNCTIONAL DIAGRAM



Manufactured under the following U.S. patent: 4,739,281

ABSOLUTE MAXIMUM RATINGS[1]

V_{DD} to DGND . . . . . −0.3 V, 17 V
V_{DD} to V_{SS} . . . . . −0.3 V, 17 V
V_{LOGIC} to DGND . . . . . −0.3 V, V_{DD}
V_{IN} to DGND . . . . . V_{SS}, V_{DD}
V_{OUT} to DGND . . . . . V_{SS}, V_{DD}
Analog Output Current . . . . . ±20 mA
(Not short-circuit protected)
Operating Temperature Range
FQ, FP, FS . . . . . −40°C to +85°C
Junction Temperature . . . . . +150°C
Storage Temperature . . . . . −65°C to +150°C
Lead Temperature (Soldering, 60 sec) . . . . . +300°C

Package Type	θ_{JA}[2]	θ_{JC}	Units
16-Pin Hermetic DIP (Q)	94	12	°C/W
16-Pin Plastic DIP (P)	76	33	°C/W
16-Pin SOIC (S)	92	27	°C/W

NOTES
[1]Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.
[2]θ_{JA} is specified for worst case mounting conditions, i.e., θ_{JA} is specified for device in socket for cerdip and plastic DIP packages; θ_{JA} is specified for device soldered to printed circuit board for SOIC package.

CAUTION

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper antistatic handling procedures.
3. Remove power before inserting or removing units from their sockets.

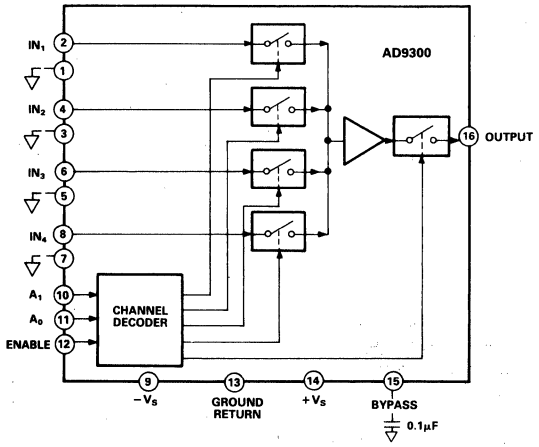
4 × 1 Wideband Video Multiplexer

AD9300

FEATURES
34MHz Full Power Bandwidth
±0.1dB Gain Flatness to 8MHz
72dB Crosstalk Rejection @ 10MHz
0.03°/0.01% Differential Phase/Gain
Cascadable for Switch Matrices
MIL-STD-883 Compliant Versions Available

APPLICATIONS
Video Routing
Medical Imaging
Electro-Optics
ECM Systems
Radar Systems
Data Acquisition

FUNCTIONAL BLOCK DIAGRAM
(Based on Cerdip)



GENERAL DESCRIPTION

The AD9300 is a monolithic high-speed video signal multiplexer useable in a wide variety of applications.

Its four channels of video input signals can be randomly switched at megahertz rates to the single output. In addition, multiple devices can be configured in either parallel or cascade arrangements to form switch matrices. This flexibility in using the AD9300 is possible because the output of the device is in a high-impedance state when the chip is not enabled; when the chip is enabled, the unit acts as a buffer with a high input impedance and low output impedance.

An advanced bipolar process provides fast, wideband switching capabilities while maintaining crosstalk rejection of 72dB at 10MHz. Full power bandwidth is a minimum 27MHz. The device can be operated from ±10V to ±15V power supplies.

The AD9300K is available in a 16-pin ceramic DIP and a 20-pin PLCC and is designed to operate over the commercial temperature range of 0 to +70°C. The AD9300TQ is a hermetic 16-pin ceramic DIP for military temperature range (−55°C to +125°C) applications. This part is also available processed to MIL-STD-883. The AD9300 is available in a 20-pin LCC as the model AD9300TE, which operates over a temperature range of −55°C to +125°C.

The AD9300 Video Multiplexer is available in versions compliant with MIL-STD-883. Refer to the Analog Devices *Military Products Databook* or current AD9300/883B data sheet for detailed specifications.

EXPLANATION OF TEST LEVELS

Test Level I – 100% production tested.
Test Level II – 100% production tested at + 25°C, and sample tested at specified temperatures.
Test Level III – Sample tested only.
Test Level IV – Parameter is guaranteed by design and characterization testing.
Test Level V – Parameter is a typical value only.
Test Level VI – All devices are 100% production tested at + 25°C. 100% production tested at temperature extremes for military temperature devices; sample tested at temperature extremes for commercial/industrial devices.

Parameter (Conditions)	Temp	Test Level	COMMERCIAL 0°C to +70°C AD9300KQ/KP Min	Typ	Max	Units
DIGITAL INPUTS						
Logic "1" Voltage	Full	VI	2			V
Logic "0" Voltage	Full	VI			0.8	V
Logic "1" Current	Full	VI			5	μA

POWER SUPPLY						
Positive Supply Current (+12V)	+25°C	I		13	16	mA
Positive Supply Current (+12V)	Full	VI		13	16	mA
Negative Supply Current (−12V)	+25°C	I		12.5	15	mA
Negative Supply Current (−12V)	Full	VI		12.5	16	mA
Power Supply Rejection Ratio ($\pm V_S = \pm 12V \pm 5\%$)	Full	VI	67	75		dB
Power Dissipation (±12V)[18]	+25°C	V		306		mW

NOTES
[1]Permanent damage may occur if any one absolute maximum rating is exceeded. Functional operation is not implied, and device reliability may be impaired by exposure to higher-than-recommended voltages for extended periods of time.
[2]Measured at extremes of temperature range.
[3]Measured as slope of V_{OUT} versus V_{IN} with $V_{IN} = \pm 1V$.
[4]Measured as worst deviation from end-point fit with $V_{IN} = \pm 1V$.
[5]Full Power Bandwith (FPBW) based on Slew Rate (SR). FPBW = $SR/2\pi V_{PEAK}$
[6]Measured between 20% and 80% transition points of ±1V output.
[7]T-Step = Sin^2X Step, when Step between 0V and +700mV points has 10%-to-90% risetime = 125ns.
[8]Measured with a pulse input having slew rate >250V/μs.
[9]Measured at output between 0.28Vdc and 1.0Vdc with V_{IN} = 284mV p–p at 3.58MHz and 4.43MHz.
[10]This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and 10MHz 2V p–p signal applied to remaining three channels. If selected channel is grounded through 75Ω, value is approximately 6dB higher.
[11]This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and 10MHz 2V p–p signal applied to one other channel. If selected channel is grounded through 75Ω, value is approximately 6dB higher. Minimum specification in ( ) applies to DIPs.
[12]Consult system timing diagram.
[13]Measured from address change to 90% point of −2V to +2V output LOW-to-HIGH transition.
[14]Measured from address change to 90% point of +2V to −2V output HIGH-to-LOW transition.
[15]Measured from 50% transition point of ENABLE input to 90% transition of 0V to −2V and 0V to +2V output.
[16]Measured from 50% transition point of ENABLE input to 10% transition of +2V to 0V and −2V to 0V output.
[17]Measured while switching between two grounded channels.
[18]Maximum power dissipation is a package-dependent parameter related to the following typical thermal impedances:
16-Pin Ceramic $\theta_{JA} = 87°C/W$; $\theta_{JC} = 25°C/W$
20-Pin LCC $\theta_{JA} = 74°C/W$; $\theta_{JC} = 10°C/W$
20-Pin PLCC $\theta_{JA} = 71°C/W$; $\theta_{JC} = 26°C/W$

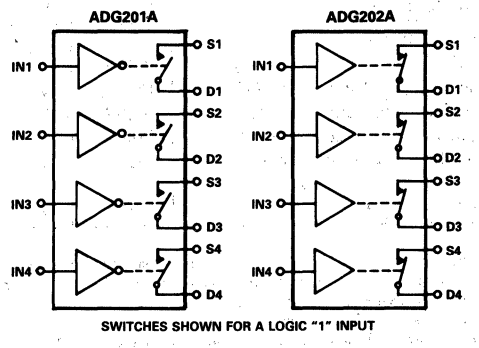
LC²MOS Quad SPST Switches

ADG201A/ADG202A

FEATURES

44V Supply Maximum Rating
±15V Analog Signal Range
Low R_{ON} (60Ω)
Low Leakage (0.5nA)
Break Before Make Switching
Extended Plastic Temperature Range (−40°C to +85°C)
Low Power Dissipation (33mW)
Available in 16-Lead DIP/ SOIC and 20-Lead PLCC/LCCC Packages
Superior Second Source:
ADG201A Replaces DG201A, HI-201
ADG202A Replaces DG202

FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The ADG201A and ADG202A are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low R_{ON}.

The ADG201A and ADG202A consist of four SPST switches. They differ only in that the digital control logic is inverted. All devices exhibit break before make switching action. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended Signal Range:
   These switches are fabricated on an enhanced LC²MOS process, resulting in high breakdown and an increased analog signal range of ±15V.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

Lead Temperature (Soldering 10sec) . . . . . +300°C

NOTE
[1]Overvoltage at IN, S or D will be clamped by diodes. Current should be limited to the Maximum Rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

FEATURES

50ns max Switching Time Over Full Temperature Range
Low R_{ON} (30Ω typ)
Single Supply Specifications for +10.8V to +16.5V Operation
Extended Plastic Temperature Range (−40°C to +85°C)
Break-Before-Make Switching
Low Leakage (100pA typ)
44V Supply max Rating
Available in 16-Lead DIP/SOIC and 20-Lead LCCC/PLCC Packages
ADG201HS (K, B, T) Replaces HI-201HS
ADG201HS (J, A, S) Replaces DG271

GENERAL DESCRIPTION

The ADG201HS is a monolithic CMOS device comprising four independently selectable SPST switches. It is designed on an enhanced LC²MOS process which gives very fast switching speeds and low R_{ON}.

The switches also feature break-before-make switching action for use in multiplexer applications and low charge injection for minimum transients on the output when switching the digital inputs.

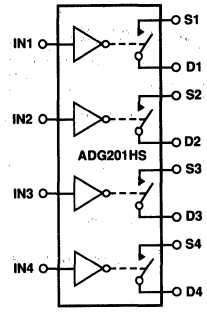
FUNCTIONAL BLOCK DIAGRAM



PRODUCT HIGHLIGHTS

1. 50ns max t_{ON} and t_{OFF}:
The ADG201HS top grades (K, B, T) have guaranteed 50ns max turn-on and turn-off times over the full operating temperature range. The lower grades (J,A,S) have guaranteed 75ns switching times over the full operating temperature range.

2. Single Supply Specifications:
The ADG201HS is fully specified for applications which require a single positive power supply in the +10.8V to +16.5V range.

3. Low Leakage:
Leakage currents in the range of 100pA make these switches suitable for high precision circuits. The added feature of break-before-make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

IN	Switch Condition
0	ON
1	OFF

Lead Temperature (Soldering 10sec)	+300°C

NOTES

[1]If V_{SS} is open circuited with V_{DD} and GND applied, the V_{SS} pin will be pulled positive, exceeding the Absolute Maximum Ratings. If this possibility exists, a Schottky diode from V_{SS} to GND (cathode end to GND) ensures that the Absolute Maximum Ratings will be observed.

[2]Overvoltage at IN, S or D, will be clamped by diodes. Current should be limited to the maximum rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

7

CAUTION:

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

SWITCHES SHOWN FOR A LOGIC "1" INPUT

GENERAL DESCRIPTION

The ADG211A and ADG212A are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low R_{ON}.

The ADG211A and ADG212A consist of four SPST switches. They differ only in that the digital control logic is inverted. In multiplexer applications, all switches exhibit break-before-make switching action when driven simultaneously. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended Signal Range:
   These switches are fabricated on an enhanced LC²MOS process, resulting in high breakdown and an increased analog signal range of ±15V.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

*N = Plastic DIP; R = 0.15" Small Outline IC (SOIC); P = Plastic Leaded Chip Carrier (PLCC). For outline information see Package Information section.

Typical Performance Characteristics

The switches can comfortably operate anywhere in the 10V to 15V single or dual supply range, with only a slight degradation in performance. The following graphs show the relevant performance curves. The test circuits and test conditions are given in a following section, "Test Circuits."

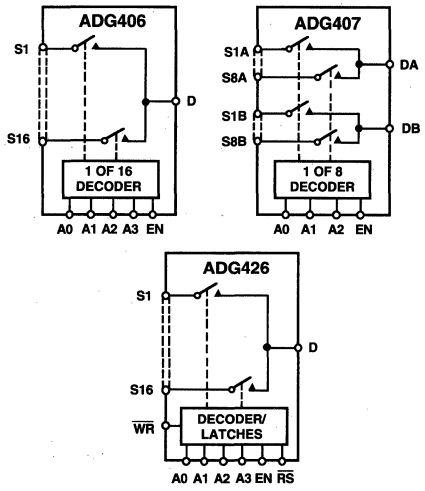
LC²MOS 8-/16-Channel High Performance Analog Multiplexers

ADG406/ADG407/ADG426

FEATURES
44 V Supply Maximum Ratings
V_{SS} to V_{DD} Analog Signal Range
Low On Resistance (80 Ω max)
Low Power
Fast Switching
t_{ON} < 160 ns
t_{OFF} < 150 ns
Break Before Make Switching Action
Plug-In Upgrade for
DG506A/ADG506A, DG507A/ADG507A, DG526/ADG526A
ADG406/ADG407 are Plug-In Replacements for DG406/DG407

APPLICATIONS
Audio and Video Routing
Automatic Test Equipment
Data Acquisition Systems
Battery Powered Systems
Sample Hold Systems
Communication Systems
Avionics

FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The ADG406, ADG407 and ADG426 are monolithic CMOS analog multiplexers. The ADG406 and ADG426 switch one of sixteen inputs to a common output as determined by the 4-bit binary address lines A0, A1, A2 and A3. The ADG426 has on-chip address and control latches that facilitate microprocessor interfacing. The ADG407 switches one of eight differential inputs to a common differential output as determined by the 3-bit binary address lines A0, A1 and A2. An EN input on all devices is used to enable or disable the device. When disabled, all channels are switched OFF.

The ADG406/ADG407/ADG426 are designed on an enhanced LC²MOS process that provides low power dissipation yet gives high switching speed and low on resistance. These features make the parts suitable for high speed data acquisition systems and audio signal switching. Low power dissipation makes the parts suitable for battery powered systems. Each channel conducts equally well in both directions when ON and has an input signal range which extends to the supplies. In the OFF condition, signal levels up to the supplies are blocked. All channels exhibit break before make switching action preventing momentary shorting when switching channels. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended Signal Range
   The ADG406/ADG407/ADG426 are fabricated on an enhanced LC²MOS process giving an increased signal range which extends to the supply rails
2. Low Power Dissipation
3. Low R_{ON}
4. Single/Dual Supply Operation
5. Single Supply Operation
   For applications where the analog signal is unipolar, the ADG406/ADG407/ADG426 can be operated from a single rail power supply. The parts are fully specified with a single +12 V power supply and will remain functional with single supplies as low as +5 V.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one absolute maximum rating may be applied at any one time.
[2]Overvoltages at A, S, D, $\overline{WR}$ or $\overline{RS}$ will be clamped by internal diodes. Current should be limited to the maximum ratings given.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

TIMING DIAGRAMS (ADG426)

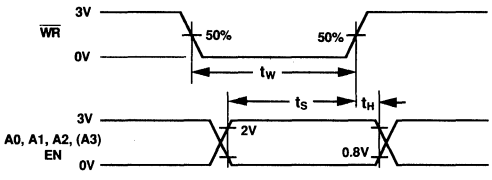

Figure 1.

Figure 1 shows the timing sequence for latching the switch address and enable inputs. The latches are level sensitive; therefore, while $\overline{WR}$ is held low, the latches are transparent and the switches respond to the address and enable inputs. This input data is latched on the rising edge of $\overline{WR}$.

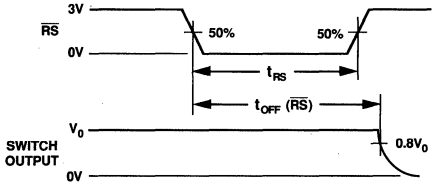

Figure 2.

Figure 2 shows the Reset Pulse Width, t_{RS}, and the Reset Turn Off Time, t_{OFF} ($\overline{RS}$).

Note: All digital input signals rise and fall times are measured from 10% to 90% of 3 V. $t_R = t_F = 20$ ns.

TERMINOLOGY

V_{DD}	Most positive power supply potential.
V_{SS}	Most negative power supply potential in dual supplies. In single supply applications, it may be connected to ground.
GND	Ground (0 V) reference.
R_{ON}	Ohmic resistance between D and S.
R_{ON} Match	Difference between the R_{ON} of any two channels.
I_S (OFF)	Source leakage current when the switch is off.
I_D (OFF)	Drain leakage current when the switch is off.
I_D, I_S (ON)	Channel leakage current when the switch is on.
V_D (V_S)	Analog voltage on terminals D, S.
C_S (OFF)	Channel input capacitance for "OFF" condition.
C_D (OFF)	Channel output capacitance for "OFF" condition.
C_D, C_S (ON)	"ON" switch capacitance.
C_{IN}	Digital input capacitance.
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition.
t_{OFF} (EN)	Delay time between the 50% and 90% points of the digital input and switch "OFF" condition.
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and the switch "ON" condition when switching from one address state to another.
t_{OPEN}	"OFF" time measured between 80% points of both switches when switching from one address state to another.
V_{INL}	Maximum input voltage for logic "0."
V_{INH}	Minimum input voltage for logic "1."
I_{INL} (I_{INH})	Input current of the digital input.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" channel.
Charge Injection	A measure of the glitch impulse transferred from the digital input to the analog output during switching.
I_{DD}	Positive supply current.
I_{SS}	Negative supply current.

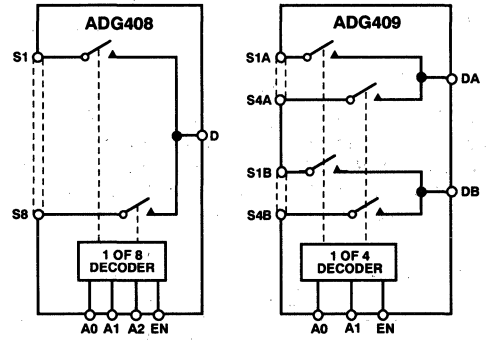
LC²MOS 4/8 Channel High Performance Analog Multiplexers

ADG408/ADG409

FEATURES
- 44 V Supply Maximum Ratings
- V_{SS} to V_{DD} Analog Signal Range
- Low On Resistance (100 Ω max)
- Low Power (I_{SUPPLY} < 75 μA)
- Fast Switching
- Break-Before-Make Switching Action
- Plug-in Replacement for DG408/DG409

APPLICATIONS
- Audio and Video Routing
- Automatic Test Equipment
- Data Acquisition Systems
- Battery Powered Systems
- Sample and Hold Systems
- Communication Systems

FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The ADG408 and ADG409 are monolithic CMOS analog multiplexers comprising 8 single channels and four differential channels respectively. The ADG408 switches one of eight inputs to a common output as determined by the 3-bit binary address lines A0, A1 and A2. The ADG409 switches one of four differential inputs to a common differential output as determined by the 2-bit binary address lines A0 and A1. An EN input on both devices is used to enable or disable the device. When disabled, all channels are switched OFF.

The ADG408/ADG409 are designed on an enhanced LC²MOS process which provides low power dissipation yet gives high switching speed and low on resistance. Each channel conducts equally well in both directions when ON and has an input signal range which extends to the supplies. In the OFF condition, signal levels up to the supplies are blocked. All channels exhibit break before make switching action preventing momentary shorting when switching channels. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

The ADG408/ADG409 are improved replacements for the DG408/DG409 Analog Multiplexers.

PRODUCT HIGHLIGHTS

1. Extended Signal Range
   The ADG408/ADG409 are fabricated on an enhanced LC²MOS process giving an increased signal range that extends to the supply rails.
2. Low Power Dissipation
3. Low R_{ON}
4. Single Supply Operation
   For applications where the analog signal is unipolar, the ADG408/ADG409 can be operated from a single rail power supply. The parts are fully specified with a single +12 V power supply and will remain functional with single supplies as low as +5 V.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

TERMINOLOGY

V_{DD}	Most positive power supply potential.
V_{SS}	Most negative power supply potential in dual supplies. In single supply applications, it may be connected to ground.
GND	Ground (0 V) reference.
R_{ON}	Ohmic resistance between D and S.
ΔR_{ON}	Difference between the R_{ON} of any two channels.
I_S (OFF)	Source leakage current when the switch is off.
I_D (OFF)	Drain leakage current when the switch is off.
I_D, I_S (ON)	Channel leakage current when the switch is on.
V_D (V_S)	Analog voltage on terminals D, S.
C_S (OFF)	Channel input capacitance for "OFF" condition.
C_D (OFF)	Channel output capacitance for "OFF" condition.
C_D, C_S (ON)	"ON" switch capacitance.
C_{IN}	Digital input capacitance.
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition.
t_{OFF} (EN)	Delay time between the 50% and 90% points of the digital input and switch "OFF" condition.
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and the switch "ON" condition when switching from one address state to another.
t_{OPEN}	"OFF" time measured between the 80% points of both switches when switching from one address state to another.
V_{INL}	Maximum input voltage for logic "0."
V_{INH}	Minimum input voltage for logic "1."
I_{INL} (I_{INH})	Input current of the digital input.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" channel.
Charge Injection	A measure of the glitch impulse transferred from the digital input to the analog output during switching.
I_{DD}	Positive supply current.
I_{SS}	Negative supply current.

DI LC²MOS
Precision Quad SPST Switches

ADG411/ADG412/ADG413

FEATURES
44 V Supply Maximum Ratings
±15 V Analog Signal Range
Low On Resistance (<35 Ω)
Ultralow Power Dissipation (35 μW)
Fast Switching Times
t_{ON} <175 ns
t_{OFF} <145 ns
Latch-up Proof
TTL/CMOS Compatible
Plug-in Replacement for DG411/DG412/DG413

APPLICATIONS
Audio and Video Switching
Automatic Test Equipment
Precision Data Acquisition
Battery Powered Systems
Sample Hold Systems
Communication Systems

GENERAL DESCRIPTION

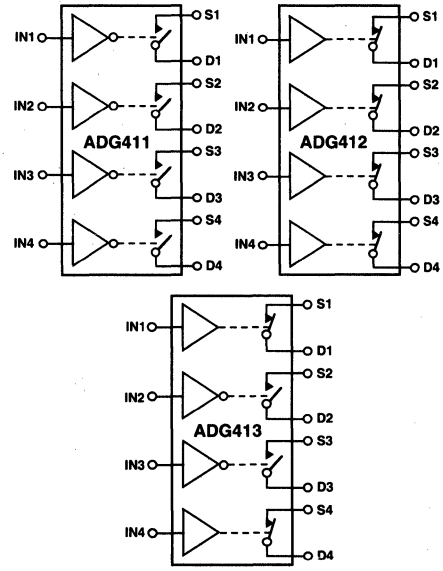
The ADG411, ADG412 and ADG413 are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS, trench isolated process which provides low power dissipation yet gives high switching speed and low on resistance. Trench isolation gives all the benefits of dielectric isolation and ensures no latch up even under extreme overvoltage conditions.

The on resistance profile is very flat over the full analog input range ensuring excellent linearity and low distortion when switching audio signals. Fast switching speed coupled with high signal bandwidth also make the parts suitable for video signal switching. CMOS construction ensures ultralow power dissipation making the parts ideally suited for portable and battery powered instruments.

The ADG411, ADG412 and ADG413 contain four independent SPST switches. The ADG411 and ADG412 differ only in that the digital control logic is inverted. The ADG411 switches are turned on with a logic low on the appropriate control input, while a logic high is required for the ADG412. The ADG413 has two switches with digital control logic similar to that of the ADG411 while the logic is inverted on the other two switches.

Each switch conducts equally well in both directions when ON and has an input signal range which extends to the supplies. In the OFF condition, signal levels up to the supplies are blocked. All switches exhibit break before make switching action for use in multiplexer applications. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

FUNCTIONAL BLOCK DIAGRAMS



SWITCHES SHOWN FOR A LOGIC "1" INPUT

PRODUCT HIGHLIGHTS

1. Extended Signal Range
   The ADG411, ADG412 and ADG413 are fabricated on an enhanced LC²MOS, trench isolated process giving an increased signal range which extends fully to the supply rails.
2. Ultralow Power Dissipation
3. Low R_{ON}
4. Trench Isolation Guards Against Latch-up
   A dielectric trench separates the P and N channel transistors thereby preventing latch-up even under severe overvoltage conditions.
5. Break Before Make Switching
   This prevents channel shorting when the switches are configured as a multiplexer.
6. Single Supply Operation
   For applications where the analog signal is unipolar, the ADG411, ADG412 and ADG413 can be operated from a single rail power supply. The parts are fully specified with a single +12 V power supply and will remain functional with single supplies as low as +5 V.

SPECIFICATIONS[1]

ESD SUSCEPTIBILITY

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 volts, which readily accumulate on the human body and on test equipment, can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper precautions are recommended to avoid any performance degradation or loss of functionality.

V_L	Logic power supply (+5 V).
GND	Ground (0 V) reference.
S	Source terminal. May be an input or output.
D	Drain terminal. May be an input or output.
IN	Logic control input.
R_{ON}	Ohmic resistance between D and S.
I_S (OFF)	Source leakage current with the switch "OFF."
I_D (OFF)	Drain leakage current with the switch "OFF."
I_D, I_S (ON)	Channel leakage current with the switch "ON."
V_D (V_S)	Analog voltage on terminals D, S.
C_S (OFF)	"OFF" switch source capacitance.
C_D (OFF)	"OFF" switch drain capacitance.
C_D, C_S (ON)	"ON" switch capacitance.

t_{ON}	Delay between applying the digital control input and the output switching on.
t_{OFF}	Delay between applying the digital control input and the output switching off.
t_D	"OFF" time or "ON" time measured between the 90% points of both switches, when switching from one address state to another.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" switch.
Charge Injection	A measure of the glitch impulse transferred from the digital input to the analog output during switching.

TRENCH ISOLATION

In the ADG411, ADG412 and ADG413, an insulating oxide layer (trench) is placed between the NMOS and the PMOS transistors of each CMOS switch. Parasitic junctions, which occur between the transistors in Junction Isolated switches, are eliminated, the result being a completely latch-up proof switch.

In Junction Isolation, the N and P wells of the PMOS and NMOS transistors form a diode which is reverse-biased under normal operation. However, during overvoltage conditions, this diode becomes forward biased. A Silicon-Controlled Rectifier (SCR) type circuit is formed by the two transistors causing a significant amplification of the current which, in turn, leads to latch-up. With Trench Isolation, this diode is removed, the result being a latch-up proof switch.

Trench Isolation also leads to lower leakage currents. The ADG411, ADG412 and ADG413 have a leakage current of 0.25 nA as compared with a leakage current of several nanoamps in non-Trench Isolated switches. Leakage current is an important parameter in sample-and-hold circuits, this current being responsible for the discharge of the holding capacitor with time causing droop. The ADG411/ADG412/ADG413's low leakage current, along with its fast switching speeds, make it suitable for fast and accurate sample-and-hold circuits.

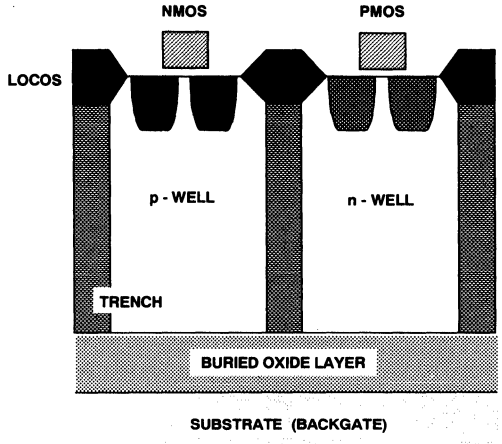

Figure 9. Trench Isolation

APPLICATION

Figure 10 illustrates a precise, fast sample-and-hold circuit. An AD845 is used as the input buffer while the output operational amplifier is an AD711. During the track mode, SW1 is closed and the output V_{OUT} follows the input signal V_{IN}. In the hold mode, SW1 is opened and the signal is held by the hold capacitor C_H.

Due to switch and capacitor leakage, the voltage on the hold capacitor will decrease with time. The ADG411/ADG412/ADG413 minimizes this droop due to its low leakage specifications. The droop rate is further minimized by the use of a polystyrene hold capacitor. The droop rate for the circuit shown is typically 30 μV/μs.

A second switch SW2, which operates in parallel with SW1, is included in this circuit to reduce pedestal error. Since both switches will be at the same potential, they will have a differential effect on the op amp AD711 which will minimize charge injection effects. Pedestal error is also reduced by the compensation network R_C and C_C. This compensation network also reduces the hold time glitch while optimizing the acquisition time. Using the illustrated op amps and component values, the pedestal error has a maximum value of 5 mV over the ±10 V input range. Both the acquisition and settling times are 850 ns.

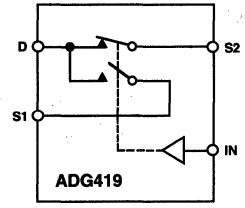
LC²MOS Precision Mini-DIP Analog Switch

ADG419

FEATURES
44 V Supply Maximum Ratings
V_{SS} to V_{DD} Analog Signal Range
Low On Resistance (< 35 Ω)
Ultralow Power Dissipation (< 35 μW)
Fast Transition Time (145 ns max)
Break-Before-Make Switching Action
Latch-Up Proof
Plug-In Replacement for DG419

APPLICATIONS
Precision Test Equipment
Precision Instrumentation
Battery Powered Systems
Sample Hold Systems

FUNCTIONAL BLOCK DIAGRAM



SWITCH SHOWN FOR A LOGIC "1" INPUT

GENERAL DESCRIPTION

The ADG419 is a monolithic CMOS SPDT switch. This switch is designed on an enhanced LC²MOS process which provides low power dissipation yet gives high switching speed, low on resistance and low leakage currents.

The on resistance profile of the ADG419 is very flat over the full analog input range ensuring excellent linearity and low distortion. The part also exhibits high switching speed and high signal bandwidth. CMOS construction ensures ultralow power dissipation making the parts ideally suited for portable and battery powered instruments.

Each switch of the ADG419 conducts equally well in both directions when ON and has an input signal range which extends to the supplies. In the OFF condition, signal levels up to the supplies are blocked. The ADG419 exhibits break-before-make switching action.

PRODUCT HIGHLIGHTS

1. Extended Signal Range
   The ADG419 is fabricated on an enhanced LC²MOS, trench isolated process giving an increased signal range that extends to the supply rails.
2. Ultralow Power Dissipation
3. Low R_{ON}
4. Trench Isolation Guards Against Latch Up
   A dielectric trench separates the P and N channel transistors thereby preventing latch-up even under severe overvoltage conditions
5. Single Supply Operation
   For applications where the analog signal is unipolar, the ADG419 can be operated from a single rail power supply. The part is fully specified with a single +12 V power supply and will remain functional with single supplies as low as +5 V.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTE

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one absolute maximum rating may be applied at any one time.

[2]Overvoltages at IN, S or D will be clamped by internal diodes. Current should be limited to the maximum ratings given.

7

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this device features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

TERMINOLOGY

V_{DD}	Most positive power supply potential.
V_{SS}	Most negative power supply potential in dual supplies. In single supply applications, it may be connected to GND.
V_L	Logic power supply (+5 V).
GND	Ground (0 V) reference.
S	Source terminal. May be an input or an output.
D	Drain terminal. May be an input or an output.
IN	Logic control input.
R_{ON}	Ohmic resistance between D and S.
I_S (OFF)	Source leakage current with the switch "OFF."
I_D (OFF)	Drain leakage current with the switch "OFF."
I_D, I_S (ON)	Channel leakage current with the switch "ON."
V_D (V_S)	Analog voltage on terminals D, S.
C_S (OFF)	"OFF" switch source capacitance.
C_D, C_S (ON)	"ON" switch capacitance.
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and the switch "ON" condition when switching from one address state to another.
t_D	"OFF" time or "ON" time measured between the 90% points of both switches when switching from one address state to the other.
V_{INL}	Maximum input voltage for logic "0."
V_{INH}	Minimum input voltage for logic "1."
I_{INL} (I_{INH})	Input current of the digital input.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" channel.
I_{DD}	Positive supply current.
I_{SS}	Negative supply current.

LC²MOS Latchable 4/8 Channel High Performance Analog Multiplexers

ADG428/ADG429

FEATURES
44 V Supply Maximum Ratings
V_{SS} to V_{DD} Analog Signal Range
Low On Resistance (60 Ω typ)
Low Power Consumption (1.6 mW max)
Low Charge Injection (<4 pC typ)
Fast Switching
Break Before make Switching Action
Plug-In Replacement for DG428/DG429

APPLICATIONS
Automatic Test Equipment
Data Acquisition Systems
Communication Systems
Avionics and Military Systems
Microprocessor Controlled Analog Systems
Medical Instrumentation

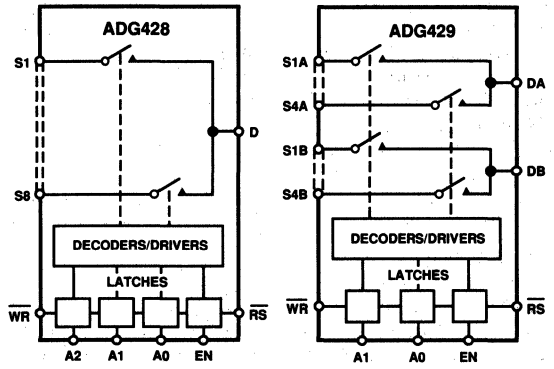
GENERAL DESCRIPTION

The ADG428 and ADG429 are monolithic CMOS analog multiplexers comprising eight single channels and four differential channels respectively. On-chip address and control latches facilitate microprocessor interfacing. The ADG428 switches one of eight inputs to a common output as determined by the 3-bit binary address lines A0, A1 and A2. The ADG429 switches one of four differential inputs to a common differential output as determined by the 2 bit binary address lines A0 and A1. An EN input on both devices is used to enable or disable the device. When disabled, all channels are switched OFF. All the control inputs, address and enable inputs are TTL compatible over the full specified operating temperature range. This makes the part suitable for bus-controlled systems such as data acquisition systems, process controls, avionics and ATEs because the TTL compatible address latches simplify the digital interface design and reduce the board space required.

The ADG428/ADG429 are designed on an enhanced LC²MOS process that provides low power dissipation yet gives high switching speed and low on resistance. Each channel conducts equally well in both directions when ON and has an input signal range that extends to the supplies. In the OFF condition, signal levels up to the supplies are blocked. All channels exhibit break before make switching action preventing momentary shorting when switching channels. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

The ADG428/ADG429 are improved replacements for the DG428/DG429 Analog Multiplexers.

FUNCTIONAL BLOCK DIAGRAMS



PRODUCT HIGHLIGHTS

1. Extended Signal Range
   The ADG428/ADG429 are fabricated on an enhanced LC²MOS process giving an increased signal range that extends to the supply rails.
2. Low Power Dissipation
3. Low R_{ON}
4. Single/Dual Supply Operation
5. Single Supply Operation
   For applications where the analog signal is unipolar, the ADG428/ADG429 can be operated from a single rail power supply. The parts are fully specified with a single +12 V power supply and will remain functional with single supplies as low as +5 V.

ADG428TQ	−55°C to +125°C	Q-18
ADG429BN	−40°C to +85°C	N-18
ADG429BP	−40°C to +85°C	P-20A
ADG429TQ	−55°C to +125°C	Q-18

NOTES
[1]To order MIL-STD-883, Class B processed parts, add /883B to T grade part numbers.
[2]N = Plastic DIP; P = Plastic Leaded Chip Carrier (PLCC); Q = Cerdip. For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

TERMINOLOGY

V_{DD}	Most positive power supply potential.
V_{SS}	Most negative power supply potential in dual supplies. In single supply applications, it may be connected to ground.
GND	Ground (0 V) reference.
R_{ON}	Ohmic resistance between D and S.
ΔR_{ON}	Difference between the R_{ON} of any two channels.
I_S (OFF)	Source leakage current when the switch is off.
I_D (OFF)	Drain leakage current when the switch is off.
I_D, I_S (ON)	Channel leakage current when the switch is on.
V_D (V_S)	Analog voltage on terminals D, S.
C_S (OFF)	Channel input capacitance for "OFF" condition.
C_D (OFF)	Channel output capacitance for "OFF" condition.
C_D, C_S (ON)	"ON" switch capacitance.
C_{IN}	Digital input capacitance.
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition.
t_{OFF} (EN)	Delay time between the 50% and 90% points of the digital input and switch "OFF" condition.
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and the switch "ON" condition when switching from one address state to another.
t_{OPEN}	"OFF" time measured between 80% points of both switches when switching from one address state to another.
V_{INL}	Maximum input voltage for logic "0".
V_{INH}	Minimum input voltage for logic "1".
I_{INL} (I_{INH})	Input current of the digital input.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" channel.
Charge Injection	A measure of the glitch impulse transferred from the digital input to the analog output during switching.
I_{DD}	Positive supply current.
I_{SS}	Negative supply current.

TIMING DIAGRAMS

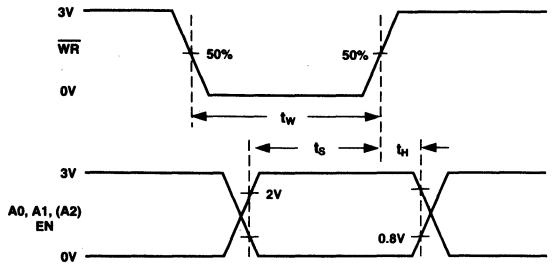

Figure 1.

Figure 1 shows the timing sequence for latching the switch address and enable inputs. The latches are level sensitive; therefore, while $\overline{WR}$ is held low, the latches are transparent and the switches respond to the address and enable inputs. This input data is latched on the rising edge of $\overline{WR}$.

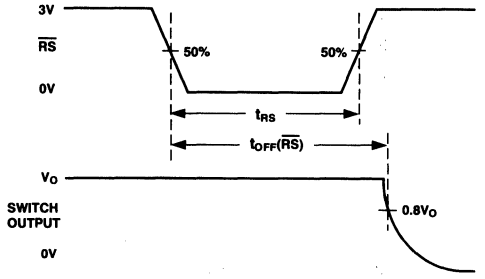

Figure 2.

Figure 2 shows the Reset Pulse Width, t_{RS}, and the Reset Turn-off Time, $t_{OFF}(\overline{RS})$.

Note: All digital input signals rise and fall times are measured from 10% to 90% of 3 V. tr = tf = 20 ns.

DI LC²MOS
Precision Quad SPST Switches

ADG431/ADG432/ADG433

FEATURES
44 V Supply Maximum Ratings
±15 V Analog Signal Range
Low On Resistance (<24 Ω)
Ultralow Power Dissipation (3.9 μW)
Low Leakage (<0.25 nA)
Fast Switching Times
t_{ON} <165 ns
t_{OFF} <130 ns
Latch-up Proof
Break-Before-Make Switching Action
TTL/CMOS Compatible
Plug-in Replacement for DG411/DG412/DG413

APPLICATIONS
Audio and Video Switching
Automatic Test Equipment
Precision Data Acquisition
Battery Powered Systems
Sample Hold Systems
Communication Systems

GENERAL DESCRIPTION

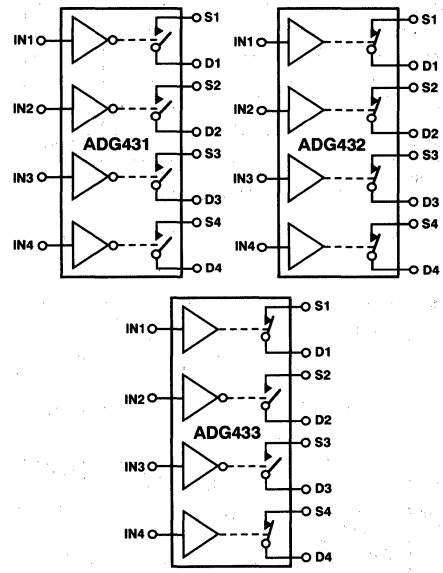
The ADG431, ADG432 and ADG433 are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS, trench isolated process which provides low power dissipation yet gives high switching speed and low on resistance. Trench isolation gives all the benefits of dielectric isolation and ensures no latch up even under extreme overvoltage conditions.

The on resistance profile is very flat over the full analog input range ensuring excellent linearity and low distortion when switching audio signals. Fast switching speed coupled with high signal bandwidth also make the parts suitable for video signal switching. CMOS construction ensures ultralow power dissipation making the parts ideally suited for portable and battery powered instruments.

The ADG431, ADG432 and ADG433 contain four independent SPST switches. The ADG431 and ADG432 differ only in that the digital control logic is inverted. The ADG431 switches are turned on with a logic low on the appropriate control input, while a logic high is required for the ADG432. The ADG433 has two switches with digital control logic similar to that of the ADG431 while the logic is inverted on the other two switches.

Each switch conducts equally well in both directions when ON and has an input signal range which extends to the supplies. In the OFF condition, signal levels up to the supplies are blocked. All switches exhibit break before make switching action for use in multiplexer applications. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

FUNCTIONAL BLOCK DIAGRAMS



SWITCHES SHOWN FOR A LOGIC "1" INPUT

PRODUCT HIGHLIGHTS

1. Extended Signal Range
   The ADG431, ADG432 and ADG433 are fabricated on an enhanced LC²MOS, trench isolated process giving an increased signal range which extends fully to the supply rails.
2. Ultralow Power Dissipation
3. Low R_{ON}
4. Trench Isolation Guards Against Latch-up
   A dielectric trench separates the P and N channel transistors thereby preventing latch-up even under severe overvoltage conditions.
5. Break Before Make Switching
   This prevents channel shorting when the switches are configured as a multiplexer.
6. Single Supply Operation
   For applications where the analog signal is unipolar, the ADG431, ADG432 and ADG433 can be operated from a single rail power supply. The parts are fully specified with a single +12 V power supply and will remain functional with single supplies as low as +5 V.

SPECIFICATIONS[1]

TERMINOLOGY

V_{DD}	Most positive power supply potential.
V_{SS}	Most negative power supply potential in dual supplies. In single supply applications, it may be connected to GND.
V_L	Logic power supply (+5 V).
GND	Ground (0 V) reference.
S	Source terminal. May be an input or output.
D	Drain terminal. May be an input or output.
IN	Logic control input.
R_{ON}	Ohmic resistance between D and S.
R_{ON} vs. V_D (V_S)	The variation in R_{ON} due to a change in the analog input voltage with a constant load current.
R_{ON} Drift	Change in R_{ON} vs. temperature.
R_{ON} Match	Difference between the R_{ON} of any two switches.
I_S (OFF)	Source leakage current with the switch "OFF."
I_D (OFF)	Drain leakage current with the switch "OFF."
I_D, I_S (ON)	Channel leakage current with the switch "ON."
V_D (V_S)	Analog voltage on terminals D, S.

C_S (OFF)	"OFF" switch source capacitance.
C_D (OFF)	"OFF" switch drain capacitance.
C_D, C_S (ON)	"ON" switch capacitance.
C_{IN}	Input Capacitance to ground of a digital input.
t_{ON}	Delay between applying the digital control input and the output switching on.
t_{OFF}	Delay between applying the digital control input and the output switching off.
t_D	"OFF" time or "ON" time measured between the 90% points of both switches, when switching from one address state to another.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" switch.
Charge Injection	A measure of the glitch impulse transferred from the digital input to the analog output during switching.

TRENCH ISOLATION

In the ADG431, ADG432 and ADG433, an insulating oxide layer (trench) is placed between the NMOS and the PMOS transistors of each CMOS switch. Parasitic junctions, which occur between the transistors in Junction Isolated switches, are eliminated, the result being a completely latch-up proof switch.

In Junction Isolation, the N and P wells of the PMOS and NMOS transistors form a diode which is reverse-biased under normal operation. However, during overvoltage conditions, this diode becomes forward biased. A Silicon-Controlled Rectifier (SCR) type circuit is formed by the two transistors causing a significant amplification of the current which, in turn, leads to latch-up. With Trench Isolation, this diode is removed, the result being a latch-up proof switch.

Trench Isolation also leads to lower leakage currents. The ADG431, ADG432 and ADG433 have a leakage current of 0.25 nA as compared with a leakage current of several nanoamps in non-Trench Isolated switches. Leakage current is an important parameter in sample-and-hold circuits, this current being responsible for the discharge of the holding capacitor with time causing droop. The ADG431/ADG432/ADG433's low leakage current, along with its fast switching speeds, make it suitable for fast and accurate sample-and-hold circuits.

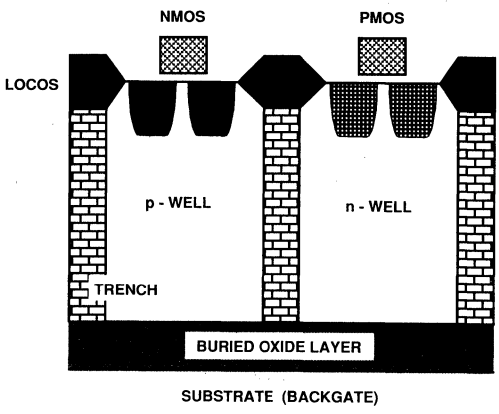

Figure 9. Trench Isolation

APPLICATION

Figure 10 illustrates a precise, fast sample-and-hold circuit. An AD845 is used as the input buffer while the output operational amplifier is an AD711. During the track mode, SW1 is closed and the output V_{OUT} follows the input signal V_{IN}. In the hold mode, SW1 is opened and the signal is held by the hold capacitor C_H.

Due to switch and capacitor leakage, the voltage on the hold capacitor will decrease with time. The ADG431/ADG432/ADG433 minimizes this droop due to its low leakage specifications. The droop rate is further minimized by the use of a polystyrene hold capacitor. The droop rate for the circuit shown is typically 30 μV/μs.

A second switch SW2, which operates in parallel with SW1, is included in this circuit to reduce pedestal error. Since both switches will be at the same potential, they will have a differential effect on the op amp AD711 which will minimize charge injection effects. Pedestal error is also reduced by the compensation network R_C and C_C. This compensation network also reduces the hold time glitch while optimizing the acquisition time. Using the illustrated op amps and component values, the pedestal error has a maximum value of 5 mV over the ±10 V input range. Both the acquisition and settling times are 850 ns.

LC²MOS Quad SPST Switches

ADG441/ADG442/ADG444

FEATURES
- 44 V Supply Maximum Ratings
- V_{SS} to V_{DD} Analog Signal Range
- Low On Resistance (< 70 Ω)
- Low ΔR_{ON} (9 Ω max)
- Low R_{ON} Match (3 Ω max)
- Low Power Dissipation
- Fast Switching Times
  - t_{ON} < 110 ns
  - t_{OFF} < 60 ns
- Low Leakage Currents (3 nA max)
- Low Charge Injection (6 pC max)
- Break-Before-Make Switching Action
- Latch-Up Proof
- Plug-In Upgrade for DG201A/ADG201A, DG202A/ADG202A, DG211/ADG211A
- Plug in Replacement for DG441/DG442/DG444

APPLICATIONS
- Audio and Video Switching
- Automatic Test Equipment
- Precision Data Acquisition
- Battery Powered Systems
- Sample Hold Systems
- Communication Systems

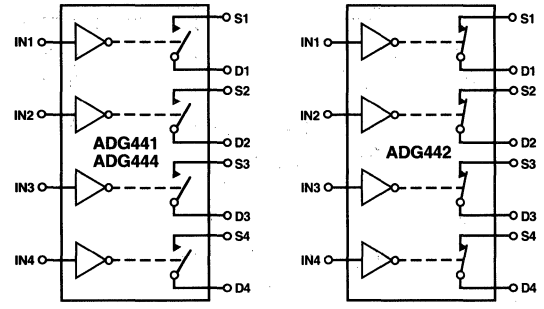
GENERAL DESCRIPTION

The ADG441, ADG442 and ADG444 are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS process that provides low power dissipation yet gives high switching speed and low on resistance.

The on resistance profile is very flat over the full analog input range ensuring good linearity and low distortion when switching audio signals. High switching speed also makes the parts suitable for video signal switching. CMOS construction ensures ultralow power dissipation making the parts ideally suited for portable and battery powered instruments.

The ADG441, ADG442 and ADG444 contain four independent SPST switches. Each switch of the ADG441 and ADG444 turns on when a logic low is applied to the appropriate control input. The ADG442 switches are turned on with a logic high on the appropriate control input. The ADG441 and ADG444 switches differ in that the ADG444 requires a 5 V logic power supply which is applied to the V_L pin. The ADG441 and ADG442 do not have a V_L pin, the logic power supply being generated internally by an on-chip voltage generator.

FUNCTIONAL BLOCK DIAGRAMS



SWITCHES SHOWN FOR A LOGIC "1" INPUT

Each switch conducts equally well in both directions when ON and has an input signal range that extends to the power supplies. In the OFF condition, signal levels up to the supplies are blocked. All switches exhibit break-before-make switching action for use in multiplexer applications. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended Signal Range
   The ADG441/ADG442/ADG444 are fabricated on an enhanced LC²MOS, trench-isolated process, giving an increased signal range that extends to the supply rails.
2. Low Power Dissipation
3. Low R_{ON}
4. Trench Isolation Guards Against Latch Up
   A dielectric trench separates the P and N channel transistors thereby preventing latch up even under severe overvoltage conditions.
5. Break-Before-Make Switching
   This prevents channel shorting when the switches are configured as a multiplexer.
6. Single Supply Operation
   For applications where the analog signal is unipolar, the ADG441/ADG442/ADG444 can be operated from a single rail power supply. The parts are fully specified with a single +12 V power supply.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one absolute maximum rating may be applied at any one time.

[2]Overvoltages at IN, S or D will be clamped by internal diodes. Current should be limited to the maximum ratings given.

TERMINOLOGY

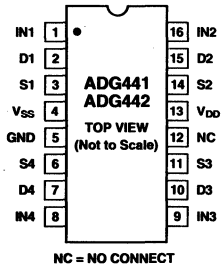
V_{DD}	Most Positive Power Supply Potential.
V_{SS}	Most Negative Power Supply Potential in dual supplies. In single supply applications, it may be connected to ground.
V_L	Logic Power Supply (+5 V).
GND	Ground (0 V) Reference.
S	Source Terminal. May be an input or output.
D	Drain Terminal. May be an input or output.
IN	Logic Control Input.
R_{ON}	Ohmic resistance between D and S.
R_{ON} Match	Difference between the R_{ON} of any two channels.
I_S (OFF)	Source leakage current with the switch "OFF."
I_D (OFF)	Drain leakage current with the switch "OFF."
I_D, I_S (ON)	Channel leakage current with the switch "ON."
V_D (V_S)	Analog voltage on terminals D, S.
C_S (OFF)	"OFF" Switch Source Capacitance.
C_D (OFF)	"OFF" Switch Drain Capacitance.
C_D, C_S (ON)	"ON" Switch Capacitance.
t_{ON}	Delay between applying the digital control input and the output switching on.
t_{OFF}	Delay between applying the digital control input and the output switching off.
t_{OPEN}	Break-Before-Make Delay when switches are configured as a multiplexer.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" switch.
Charge Injection	A measure of the glitch impulse transferred from the digital input to the analog output during switching.

7

CAUTION

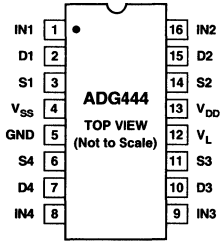
ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

ADG441/ADG442 PIN CONFIGURATION (DIP/SOIC)



NC = NO CONNECT

ADG444 PIN CONFIGURATION (DIP/SOIC)



TRENCH ISOLATION

In the ADG441, ADG442 and ADG444, an insulating oxide layer (trench) is placed between the NMOS and the PMOS transistors of each CMOS switch. Parasitic junctions, which occur between the transistors in junction isolated switches, are eliminated, the result being a completely latch-up proof switch.

In junction isolation, the N and P wells of the PMOS and NMOS transistors form a diode that is reverse-biased under normal operation. However, during overvoltage conditions, this diode becomes forward biased. A silicon-controlled rectifier (SCR) type circuit is formed by the two transistors causing a significant amplification of the current which, in turn, leads to latch up. With trench isolation, this diode is removed, the result being a latch-up proof switch.

Trench isolation also leads to lower leakage currents. The ADG441, ADG442 and ADG444 have a leakage current of 0.5 nA as compared with a leakage current of several nanoamperes in non-trench isolated switches. Leakage current is an important parameter in sample-and-hold circuits, this current being responsible for the discharge of the holding capacitor with time causing droop. The ADG441/ADG442/ADG444's low leakage current, along with its fast switching speeds, make it suitable for fast and accurate sample-and-hold circuits.

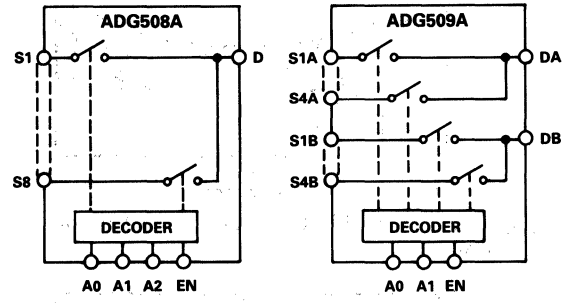
ANALOG DEVICES

CMOS 4/8 Channel Analog Multiplexers

ADG508A/ADG509A

FEATURES
- 44V Supply Maximum Rating
- V_{SS} to V_{DD} Analog Signal Range
- Single/Dual Supply Specifications
- Wide Supply Ranges (10.8V to 16.5V)
- Extended Plastic Temperature Range (−40°C to +85°C)
- Low Power Dissipation (28mW max)
- Low Leakage (20pA typ)
- Available in 16-Lead DIP/SOIC and 20-Lead PLCC/LCCC Packages
- Superior Alternative to:
  - DG508A, HI-508
  - DG509A, HI-509

FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The ADG508A and ADG509A are CMOS monolithic analog multiplexers with 8 channels and dual 4 channels respectively. The ADG508A switches one of 8 inputs to a common output depending on the state of three binary addresses and an enable input. The ADG509A switches one of 4 differential inputs to a common differential output depending on the state of two binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG508A and ADG509A are designed on an enhanced LC^{2}MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Extended Signal Range:
   The enhanced LC^{2}MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
3. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
4. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

TERMINOLOGY

R_{ON}	Ohmic resistance between terminals D and S
R_{ON} Match	Difference between the R_{ON} of any two channels
R_{ON} Drift	Change in R_{ON} versus temperature
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_S (V_D)	Analog voltage on terminal S or D
C_S (OFF)	Channel input capacitance for "OFF" condition
C_D (OFF)	Channel output capacitance for "OFF" condition
C_{IN}	Digital input capacitance
t_{OFF} (EN)	Delay time between the 50% and 10% points of the digital input and switch "OFF" condition
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and switch "ON" condition when switching from one address state to another
t_{OPEN}	"OFF" time measured between 50% points of both switches when switching from one address state to another
V_{INL}	Maximum input voltage for Logic "0"
V_{INH}	Minimum input voltage for Logic "1"
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current

Derates above +75°C by . . . . . 6mW/°C

Operating Temperature
Commercial (K Version) . . . . . −40°C to +85°C
Industrial (B Version) . . . . . −40°C to +85°C
Extended (T Version) . . . . . −55°C to +125°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Overvoltage at A, EN, S or D will be clamped by diodes. Current should be limited to the Maximum Rating above.

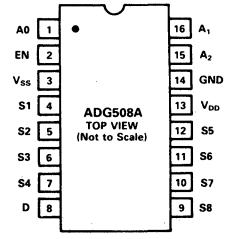
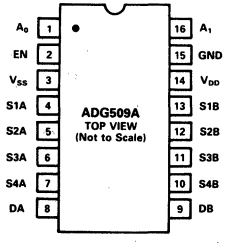
CAUTION

ESD (Electro-Static-Discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

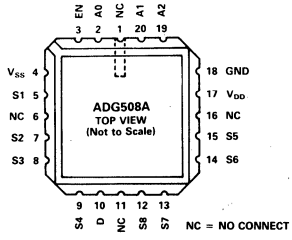
PIN CONFIGURATIONS

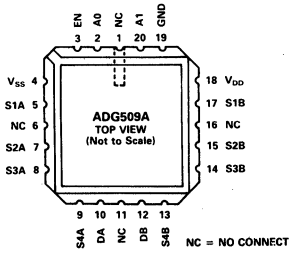
DIP, SOIC



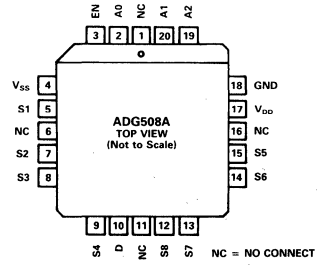


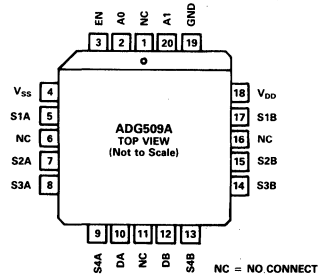
LCCC





PLCC





LC²MOS 4/8 Channel Fault-Protected Analog Multiplexers

ADG508F/ADG509F/ADG528F/ADG529F

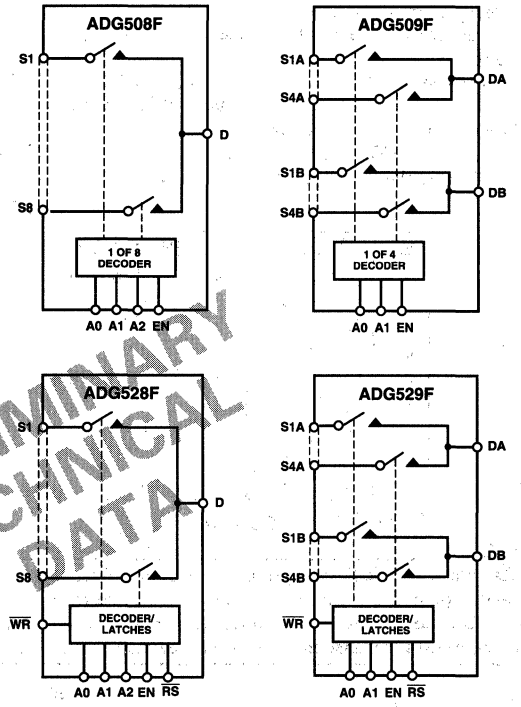
FEATURES

Wide Supply Ranges (10.8 V to 16.5 V)
Low On Resistance (300 Ω max)
Fast Switching Times
t_{ON} 300 ns max
t_{OFF} 300 ns max
Low Power Dissipation (3.3 mW max)
Fault and Overvoltage Protection
All Switches OFF with Power Supply OFF
ON Channel Turns OFF if Overvoltage Occurs
Latch-Up Proof Construction
Break-Before-Make Construction
TTL and CMOS Compatible Inputs
Superior Alternative to
MAX358/MAX359
DG458/DG459

APPLICATIONS

Data Acquisition Systems
Industrial and Process Control Systems
Avionics Test Equipment
Signal Routing Between Systems
High Reliability Control Systems

FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The ADG508F, ADG509F, ADG528F and ADG529F are CMOS analog multiplexers comprising eight single channels and four differential channels respectively which have fault protection. Using a series n-channel, p-channel, n-channel MOSFET structure, both device and signal source protection is provided in the event of an overvoltage or power loss. The multiplexer can withstand continuous overvoltage inputs up to ±35 V. During fault conditions, the multiplexer input (or output) appears as an open circuit and only a few nanoamperes of leakage current will flow. This protects not only the multiplexer and the circuitry driven by the multiplexer, but also protects the sensors or signal sources that drive the multiplexer.

The ADG508F/ADG509F/ADG528F/ADG529F are designed on an enhanced LC²MOS, trench-isolated process that provides low power dissipation yet gives high switching speed and low on resistance. All channels exhibit break-before-make switching action preventing momentary shorting when switching channels.

The ADG508F and ADG528F switch one of eight inputs to a common output as determined by the 3-bit binary address lines A0, A1 and A2. The ADG509F and ADG529F switch one of four differential inputs to a common differential output as determined by the 2-bit binary address lines A0 and A1. The ADG528F and ADG529F have on-chip address and control latches that facilitate microprocessor interfacing. An EN input on each device is used to enable or disable the device. When disabled, all channels are switched OFF.

PRODUCT HIGHLIGHTS

1. Fault Protection
   The ADG508F/ADG509F/ADG528F/ADG529F can withstand continuous voltage inputs up to ±35 V. When a fault occurs, due to the power supplies being turned off or due to an overvoltage being applied to the ADG508F/ADG509F/ADG528F/ADG529F, all the channels are turned off and only a leakage current of a few nanoamperes flows.
2. Dual Supply Specifications with a Wide Tolerance
   The devices are specified in the 10.8 V to 16.5 V range.
3. Low R_{ON}
4. Fast Switching Times
5. Break-Before-Make Switching
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
6. Trench Isolation Guards Against Latch Up
   A dielectric trench separates the p and n-channel MOSFETs thereby preventing latch-up.

This is a preliminary data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

SPECIFICATIONS[1]

Dual Supply (V_{DD} = +10.8 V to +16.5 V, V_{SS} = −10.8 V to −16.5 V, GND = 0 V, unless otherwise noted)

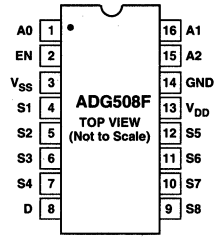
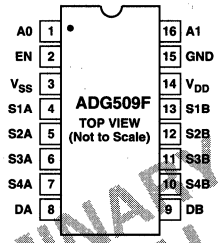
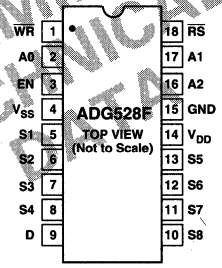
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one absolute maximum rating may be applied at any one time.

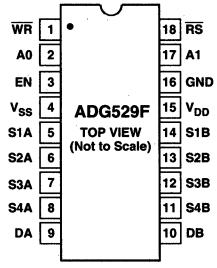
PIN CONFIGURATIONS

DIP

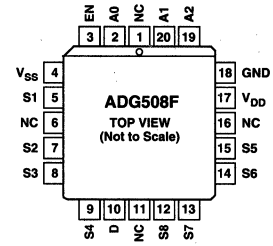


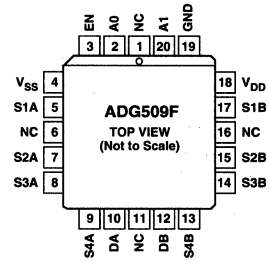


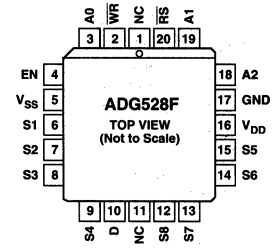


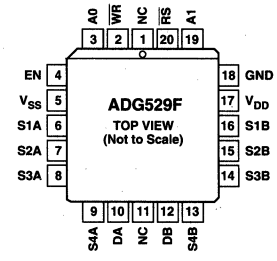


PLCC









NC = NO CONNECT

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

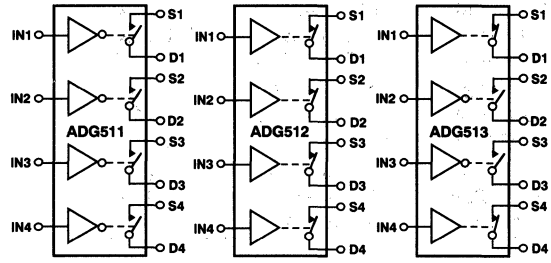
DI LC²MOS
Precision 5 V/3 V Quad SPST Switches

ADG511/ADG512/ADG513

FEATURES
+3 V, +5 V or ±5 V Power Supplies
Ultralow Power Dissipation (<0.5 μW)
Low Leakage (<100 pA)
Low On Resistance (<50 Ω)
Fast Switching Times
Low Charge Injection
Latch-Up Proof
TTL/CMOS Compatible
16-Pin DIP or SOIC Package

APPLICATIONS
Battery Powered Instruments
Single Supply Systems
Remote Powered Equipment
+5 V Supply Systems
Computer Peripherals such as Disk Drives
Precision Instrumentation
Audio and Video Switching
Automatic Test Equipment
Precision Data Acquisition
Sample Hold Systems
Communication Systems
Compatible with ±5 V Supply DACs and ADCs such as AD7840/8, AD7870/1/2/4/5/6/8

FUNCTIONAL BLOCK DIAGRAM



SWITCHES SHOWN FOR A LOGIC "1" INPUT

GENERAL DESCRIPTION

The ADG511, ADG512 and ADG513 are monolithic CMOS ICs containing four independently selectable analog switches. These switches feature low, well-controlled on resistance and wide analog signal range, making them ideal for precision analog signal switching.

These switch arrays are fabricated using Analog Devices' advanced linear compatible CMOS (LC²MOS) process which offers the additional benefits of low leakage currents, ultralow power dissipation and low capacitance for fast switching speeds with minimum charge injection. These features make the ADG511, ADG512 and ADG513 the optimum choice for a wide variety of signal switching tasks in precision analog signal processing and data acquisition systems.

The ability to operate from single +3 V, +5 V or ±5 V bipolar supplies make the ADG511, ADG512 and ADG513 perfect for use in battery-operated instruments, 4–20 mA loop systems and with the new generation of DACs and ADCs from Analog Devices. The use of 5 V supplies and reduced operating currents give much lower power dissipation than devices operating from ±15 V supplies.

The ADG511, ADG512 and ADG513 contain four independent SPST switches. The ADG511 and ADG512 differ only in that the digital control logic is inverted. The ADG511 switch is turned on with a logic low on the appropriate control input, while a logic high is required for the ADG512. The ADG513 contains two switches whose digital control logic is similar to that of the ADG511 while the logic is inverted in the remaining two switches.

PRODUCT HIGHLIGHTS

1. +5 Volt Single Supply Operation
   The ADG511/ADG512/ADG513 offers high performance, including low on resistance and wide signal range, fully specified and guaranteed with +3 V, ±5 V as well as +5 V supply rails.
2. Ultralow Power Dissipation
   CMOS construction ensures ultralow power dissipation.
3. Low R_{ON}
4. Trench Isolation Guards Against Latch-up
   A dielectric trench separates the P and N channel transistors thereby preventing latch-up even under severe overvoltage conditions.
5. Break Before Make Switching
   Switches are guaranteed to have break-before-make operation. This allows multiple outputs to be tied together for multiplexer applications without the possibility of momentary shorting between channels.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one absolute maximum rating may be applied at any one time.
[1]Overvoltages at IN, S or D will be clamped by internal diodes. Current should be limited to the maximum ratings given.

ESD SUSCEPTIBILITY

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 volts, which readily accumulate on the human body and on test equipment, can discharge without detection. Although the ADG511/ADG512/ADG513 features proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid any performance degradation or loss of functionality.

ORDERING GUIDE

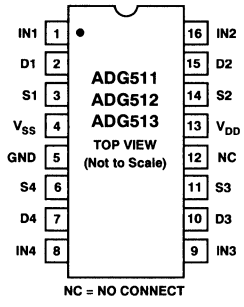
PIN CONFIGURATION (DIP/SOIC)



Truth Table (ADG511/ADG512)

ADG511 In	ADG512 In	Switch Condition
0	1	ON
1	0	OFF

Truth Table (ADG513)

Logic	Switch 1, 4	Switch 2, 3
0	OFF	ON
1	ON	OFF

TERMINOLOGY

V_{DD}	Most positive power supply potential.
V_{SS}	Most negative power supply potential in dual supplies. In single supply applications, it may be connected to GND.
GND	Ground (0 V) reference.
S	Source terminal. May be an input or output.
D	Drain terminal. May be an input or output.
IN	Logic control input.
R_{ON}	Ohmic resistance between D and S.
I_S (OFF)	Source leakage current with the switch "OFF."
I_D (OFF)	Drain leakage current with the switch "OFF."
I_D, I_S (ON)	Channel leakage current with the switch "ON."
V_D (V_S)	Analog voltage on terminals D, S.
C_S (OFF)	"OFF" switch source capacitance.
C_D (OFF)	"OFF" switch drain capacitance.
C_D, C_S (ON)	"ON" switch capacitance.
t_{ON}	Delay between applying the digital control input and the output switching on.
t_{OFF}	Delay between applying the digital control input and the output switching off.
t_D	"OFF" or "ON" time measured between the 90% points of both switches when switching from one address state to another.
Crosstalk	A measure of unwanted signal which is coupled through from one channel to another as a result of parasitic capacitance.
Off Isolation	A measure of unwanted signal coupling through an "OFF" switch.
Charge Injection	A measure of the glitch impulse transferred from the digital input to the analog output during switching.

TRENCH ISOLATION

In the ADG511/ADG512/ADG513, an insulating oxide layer (trench) is placed between the NMOS and the PMOS transistors of each CMOS switch. Parasitic junctions, which occur between the transistors in Junction Isolated switches, are eliminated. The result is a completely latch-up proof switch.

In Junction Isolation, the N and P wells of the PMOS and NMOS transistors form a diode which is reverse-biased under normal operation. However, during overvoltage conditions, this diode becomes forward biased. A Silicon-Controlled Rectifier (SCR) type circuit is formed by the two transistors causing a significant amplification of the current which, in turn, leads to latch-up. With Trench Isolation, this diode is removed, the result being a latch-up proof switch.

Trench Isolation also leads to lower leakage currents. The ADG511/ADG512/ADG513 has a leakage current of 0.1 nA as compared with a leakage current of several nanoamps in non-Trench Isolated switches. Leakage current is an important parameter in sample-and-hold circuits, this current being responsible for the discharge of the holding capacitor with time causing droop. The ADG511/ADG512/ADG513's low leakage current, along with its fast switching speeds, make it suitable for fast and accurate sample-and-hold circuits.

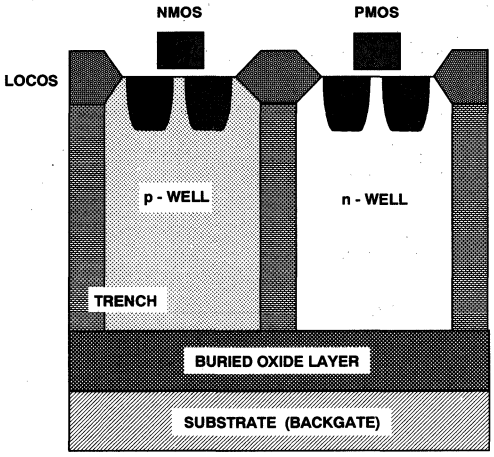

Figure 9. Trench Isolation

APPLICATION

Figure 10 illustrates a precise sample-and-hold circuit. An AD845 is used as the input buffer while the output operational amplifier is an OP-07. During the track mode, SW1 is closed and the output V_{OUT} follows the input signal V_{IN}. In the hold mode, SW1 is opened and the signal is held by the hold capacitor C_H.

Due to switch and capacitor leakage, the voltage on the hold capacitor will decrease with time. The ADG511/ADG512/ADG513 minimizes this droop due to its low leakage specifications. The droop rate is further minimized by the use of a polystyrene hold capacitor. The droop rate for the circuit shown is typically 15 μV/μs.

A second switch SW2, which operates in parallel with SW1, is included in this circuit to reduce pedestal error. Since both switches will be at the same potential, they will have a differential effect on the op amp OP-07 which will minimize charge injection effects. Pedestal error is also reduced by the compensation network R_C and C_C. This compensation network also reduces the hold time glitch while optimizing the acquisition time. Using the illustrated op amps and component values, the pedestal error has a maximum value of 5 mV over the ±3 V input range. The acquisition time is 2.5 μs while the settling time is 1.85 μs.

GENERAL DESCRIPTION

The MUX-08 is a monolithic eight-channel analog multiplexer which connects a single output to one of the eight analog inputs depending upon the state of a 3-bit binary address.

The MUX-24 is a monolithic four-channel differential analog multiplexer configured in a double pole, four-position (plus OFF) electronic switch array. A two-bit binary input address connects a pair of independent analog inputs from each four-channel input section to the corresponding pair of independent analog outputs.

All switches in the MUX-08/MUX-24 are turned OFF by applying logic "0" to the ENABLE pin, thereby providing a package select function.

Fabricated with Precision Monolithics' high performance Bipolar-JFET technology, these devices offer low, constant "ON" resistance, low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. These multiplexers do not suffer from latch-up or static charge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pull-up resistors over the full operating temperature range.

For single sixteen-channel and dual eight-channel models, refer to the MUX-16/MUX-28 data sheet.

Negative Supply Current	I−	All Digital Inputs Logic "0" or "1"		—	—	5	—	—	5	mA

NOTES:

1. Conditions applied to leakage tests insure worst case leakages. Exceeding 11V on the analog input may cause an "OFF" channel to turn "ON".
2. $R_L = 10M\Omega$, $C_L = 10pF$.
3. Crosstalk is measured by driving channel 8 with channel 4 "ON". $R_L = 1M\Omega$, $C_L = 10pF$, $V_S = 5V$ RMS, f = 500kHz.
4. "OFF" isolation is measured by driving channel 8 with ALL channels "OFF". $R_L = 1k\Omega$, $C_L = 10pF$, $V_S = 5V$ RMS, f = 500kHz. C_{DS} is computed from the OFF isolation measurement.
5. Sample tested.
6. Guaranteed by leakage current and R_{ON} tests.
7. Leakage tests are performed only on military temperature grades at 125°C.

16-Channel/Dual 8-Channel JFET Analog Multiplexers (Overvoltage Protected)

MUX16/MUX28

FEATURES

- **JFET Switches Rather Than CMOS**
- **Highly Resistant To Static Discharge Damage**
- **No SCR Latch-up Problems**
- **Low "ON" Resistance — 290Ω Typical**
- **Low Leakage Current**
- **Digital Inputs Compatible With TTL and CMOS**
- **Break-Before-Make Action**
- **125° C Temperature-Tested Dice Available**
- **Overvoltage Protected**
- **Supply Loss Protection**
- **MUX-16 Pin Compatible With DG506, HI-506A, AD7506**
- **MUX-28 Pin Compatible With DG507, HI-507A, AD7507**
- **Available In Die Form**

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

GENERAL DESCRIPTION

The MUX-16 is a monolithic 16-channel analog multiplexer which connects a single output to 1 of the 16 analog inputs depending upon the state of a 4-bit binary address. Disconnection of the output is provided by a logical "0" at the ENABLE input, thereby providing a package selection function.

The MUX-28 is a monolithic 8-channel differential analog multiplexer configured in a double pole, 8-position (plus OFF) electronic switch array. A 3-bit binary input address connects a pair of independent analog inputs from each 8-channel input section to the corresponding pair of independent analog outputs. Disconnection of both inputs is provided by a logical "0" at the ENABLE input, thereby offering a package select function.

Fabricated with Precision Monolithics' high performance Bipolar-JFET technology, these devices offer low, constant "ON" resistance. Performance advantages include low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. These multiplexers do not suffer from latch-up or static discharge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pull-up resistors. For single 8-channel and dual 4-channel models, refer to the MUX-08/MUX-24 data sheet.

ANALOG DEVICES

Quad SPST JFET Analog Switch

SW06

FEATURES

- **Two Normally Open and Two Normally Closed SPST Switches with Disable**
- **Switches can be Easily Configured as a Dual SPDT or a DPDT**
- **Highly Resistant to Static Discharge Destruction**
- **Higher Resistance to Radiation Than Analog Switches Designed with MOS Devices**
- **Guaranteed R_{ON} Matching ..... 10% Max**
- **Guaranteed Switching Speeds ..... T_{ON} = 500ns Max**
  T_{OFF} = 400ns Max
- **Guaranteed Break-Before-Make Switching**
- **Low "ON" Resistance ..... 80Ω Max**
- **Low R_{ON} Variation from Analog Input Voltage 5%**
- **Low Total Harmonic Distortion 0.01%**
- **Low Leakage Currents at High Temperature:**
  T_A = 125° C ..... 100nA Max
  T_A = 85° C ..... 30nA Max
- **Digital Inputs TTL/CMOS Compatible and Independent of V+**
- **Improved Specifications and Pin Compatible to LF-11333/13333**
- **Dual or Single Power Supply Operation**
- **Available in Die Form**

PIN CONNECTIONS

Switches are shown in the logic "0" input state and DIS = "1"

1 or NC	1	ON	OFF

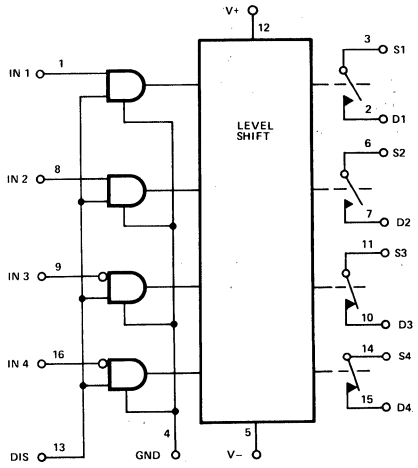
GENERAL DESCRIPTION

The SW-06 is a four channel single-pole, single-throw analog switch that employs both bipolar and ion-implanted FET devices. The SW-06 FET switches use bipolar digital logic inputs which are more resistant to static electricity than CMOS devices. Ruggedness and reliability are inherent in the SW-06 design and construction technology.

Increased reliability is complemented by excellent electrical specifications. Potential error sources are reduced by minimizing "ON" resistance and controlling leakage currents at high temperatures. The switching FET exhibits minimal R_{ON} variation over a 20V analog signal range and with power supply voltage changes. Operation from a single positive power supply voltage is possible. With V+ = 36V, V– = 0V, the analog signal range will extend from ground to +32V.

PNP logic inputs are TTL and CMOS compatible to allow the SW-06 to upgrade existing designs. The logic "0" and logic "1" input currents are at micro-ampere levels reducing loading on CMOS and TTL logic.

FUNCTIONAL DIAGRAM



ORDERING INFORMATION †

PLASTIC 16-PIN	CERDIP 16-PIN	LCC 20-CONTACT	OPERATING TEMPERATURE RANGE
–	SW06BQ*	SW06BRC/883	MIL
SW06GP	SW06FQ	–	XIND
SW06GS	–	–	XIND

* For devices processed in total compliance to MIL-STD-883, add /883 after part number. Consult factory for 883 data sheet.

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

ABSOLUTE MAXIMUM RATINGS (Note 1)

Operating Temperature Range
- SW-06BQ, BRC ..... –55°C to +125°C
- SW-06FQ ..... –40°C to +85°C
- SW-06GP, GS ..... –40°C to +85°C

Storage Temperature Range ..... –65°C to +150°C
Lead Temperature (Soldering, 60 sec) ..... 300°C
Maximum Junction Temperature ..... 150°C
V+ Supply To V– Supply 36V
V+ Supply to Ground 36V
Logic Input Voltage ..... (–4V or V–) to V+ Supply
Analog Input Voltage Range
Continuous ..... V– Supply to V+ Supply +20V

Maximum Current Through
Any Pin Including Switch 30mA

PACKAGE TYPE	Θ_{JA} (Note 2)	Θ_{JC}	UNITS
16-Pin Hermetic DIP (Q)	100	16	°C/W
16-Pin Plastic DIP (P)	82	39	°C/W
20-Contact LCC (RC)	98	38	°C/W
16-Pin SOL (S)	98	30	°C/W

NOTES:
1. Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.
2. Θ_{JA} is specified for worst case mounting conditions, i.e., Θ_{JA} is specified for device in socket for CerDIP, P-DIP, and LCC packages; Θ_{JA} is specified for device soldered to printed circuit board for SO package.

ELECTRICAL CHARACTERISTICS at V+ = 15V, V– = –15V and T_A = 25°C, unless otherwise noted.

NOTES:

1. V_S = 0V, I_S = 100μA. Specified as a percentage of $R_{AVERAGE}$ where:

$$R_{AVERAGE} = \frac{R_{ON1} + R_{ON2} + R_{ON3} + R_{ON4}}{4}$$

2. Guaranteed by design.
3. Switch is guaranteed by design to provide break-before-make operation.
4. Current tested at V_{IN} = 2.0V. This is worst case condition.
5. Switch being tested ON or OFF as indicated, V_{INH} = 2.0V or V_{INL} = 0.8V, per logic truth table.
6. Also applies to disable pin.
7. Parameter tested only at T_A = +125°C for military grade device.
8. Guaranteed by R_{ON} and leakage tests. For normal operation maximum analog signal voltages should be restricted to less than (V+) –4V.
9. Sample tested.

High Precision 2.5V IC Reference

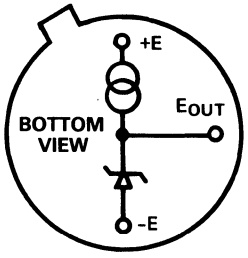
AD580*

FEATURES

Laser Trimmed to High Accuracy: 2.500V ±0.4%
3-Terminal Device: Voltage In/Voltage Out
Excellent Temperature Stability: 10ppm/°C (AD580M, U)
Excellent Long Term Stability: 250μV (25μV/Month)
Low Quiescent Current: 1.5mA max
Small, Hermetic IC Package: TO-52 Can
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM†

TO-52



8

PRODUCT DESCRIPTION

The AD580 is a three-terminal, low cost, temperature compensated, bandgap voltage reference which provides a fixed 2.5V output for inputs between 4.5V and 30V. A unique combination of advanced circuit design and laser-wafer-trimmed thin-film resistors provide the AD580 with an initial tolerance of ±0.4%, a temperature stability of better than 10ppm/°C and long-term stability of better than 250μV. In addition, the low quiescent current drain of 1.5mA max offers a clear advantage over classical zener techniques.

The AD580 is recommended as a stable reference for all 8-, 10- and 12-bit D-to-A converters that require an external reference. In addition, the wide input range of the AD580 allows operation with 5 volt logic supplies making the AD580 ideal for digital panel meter applications or whenever only a single logic power supply is available.

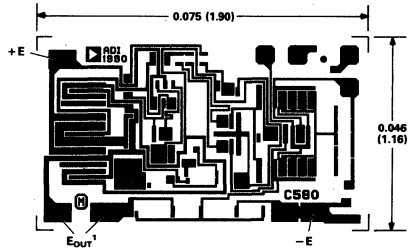
The AD580J, K, L and M are specified for operation over the 0 to +70°C temperature range; the AD580S, T and U are specified for operation over the extended temperature range of -55°C to +125°C.

PRODUCT HIGHLIGHTS

1. Laser-trimming of the thin-film resistors minimizes the AD580 output error. For example, the AD580L output tolerance is ±10mV.
2. The three-terminal voltage in/voltage out operation of the AD580 provides regulated output voltage without any external components.
3. The AD580 provides a stable 2.5V output voltage for input voltages between 4.5V and 30V. The capability to provide a stable output voltage using a 5-volt input makes the AD580 an ideal choice for systems that contain a single logic power supply.
4. Thin film resistor technology and tightly controlled bipolar processing provide the AD580 with temperature stabilities to 10ppm/°C and long term stability better than 250μV.
5. The low quiescent current drain of the AD580 makes it ideal for CMOS and other low power applications.
6. The AD580 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD580/883B data sheet for detailed specifications.

AD580 CHIP DIMENSIONS AND PAD LAYOUT

Dimensions shown in inches and (mm).



NOTE
†BOTH E_{OUT} PADS MUST BE CONNECTED TO THE OUTPUT.

The AD580 is also available in chip form. Consult the factory for specifications and applications information.

PRODUCT DESCRIPTION

The AD581 is a three-terminal, temperature compensated, monolithic band-gap voltage reference which provides a precise 10.00 volt output from an unregulated input level from 12 to 30 volts. Laser Wafer Trimming (LWT) is used to trim both the initial error at +25°C as well as the temperature coefficient, which results in high precision performance previously available only in expensive hybrids or oven-regulated modules. The 5mV initial error tolerance and 5ppm/°C guaranteed temperature coefficient of the AD581L represent the best performance combination available in a monolithic voltage reference.

The band-gap circuit design used in the AD581 offers several advantages over classical Zener breakdown diode techniques. Most important, no external components are required to achieve full accuracy and stability of significance to low power systems. In addition, total supply current to the device, including the output buffer amplifier (which can supply up to 10mA) is typically 750μA. The long-term stability of the band-gap design is equivalent or superior to selected Zener reference diodes.

The AD581 is recommended for use as a reference for 8-, 10- or 12-bit D/A converters which require an external precision reference. The device is also ideal for all types of A/D converters up to 14 bit accuracy, either successive approximation or integrating designs, and in general can offer better performance than that provided by standard self-contained references.

The AD581J, K, and L are specified for operation from 0 to +70°C; the AD581S, T, and U are specified for the −55°C to +125°C range. All grades are packaged in a hermetically-sealed three-terminal TO-5 metal can.

***Covered by Patent Nos. 3,887,863; RE 30,586**

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficient results in very low errors over temperature without the use of external components. The AD581L has a maximum deviation from 10.000 volts of ±7.25mV from 0 to +70°C, while the AD581U guarantees ±15mV maximum total error without external trims from −55°C to +125°C.
2. Since the laser trimming is done on the wafer prior to separation into individual chips, the AD581 will be extremely valuable to hybrid designers for its ease of use, lack of required external trims, and inherent high performance.
3. The AD581 can also be operated in a two-terminal "Zener" mode to provide a precision negative 10 volt reference with just one external resistor to the unregulated supply. The performance in this mode is nearly equal to that of the standard three-terminal configuration.
4. Advanced circuit design using the band-gap concept allows the AD581 to give full performance with an unregulated input voltage down to 13 volts. With an external resistor, the device will operate with a supply as low as 11.4 volts.
5. The AD581 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD581/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

8

PRODUCT DESCRIPTION

The AD584 is an eight-terminal precision voltage reference offering pin-programmable selection of four popular output voltages: 10.000V, 7.500V, 5.000V and 2.500V. Other output voltages, above, below or between the four standard outputs, are available by the addition of external resistors. Input voltage may vary between 4.5 and 30 volts.

Laser Wafer Trimming (LWT) is used to adjust the pin-programmable output levels and temperature coefficients, resulting in the most flexible high precision voltage reference available in monolithic form.

In addition to the programmable output voltages, the AD584 offers a unique strobe terminal which permits the device to be turned on or off. When the AD584 is used as a power supply reference, the supply can be switched off with a single, low-power signal. In the "off" state the current drain by the AD584 is reduced to about 100μA. In the "on" state the total supply current is typically 750μA including the output buffer amplifier.

The AD584 is recommended for use as a reference for 8-, 10- or 12-bit D/A converters which require an external precision reference. The device is also ideal for all types of A/D converters of up to 14 bit accuracy, either successive approximation or integrating designs, and in general can offer better performance than that provided by standard self-contained references.

The AD584J, K and L are specified for operation from 0 to +70°C; the AD584S and T are specified for the -55°C to +125°C range. All grades are packaged in a hermetically sealed eight-terminal TO-99 metal can; the AD584J and K are also available in an 8-pin plastic DIP.

PRODUCT HIGHLIGHTS

1. The flexibility of the AD584 eliminates the need to design-in and inventory several different voltage references. Furthermore one AD584 can serve as several references simultaneously when buffered properly.
2. Laser trimming of both initial accuracy and temperature coefficient results in very low errors over temperature without the use of external components. The AD584LH has a maximum deviation from 10.000 volts of ±7.25mV from 0 to +70°C.
3. The AD584 can be operated in a two-terminal "Zener" mode at 5 volts output and above. By connecting the input and the output, the AD584 can be used in this "Zener" configuration as a negative reference.
4. The output of the AD584 is configured to sink or source currents. This means that small reverse currents can be tolerated in circuits using the AD584 without damage to the reference and without disturbing the output voltage (10V, 7.5V and 5V outputs).
5. The AD584 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD584/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

APPLYING THE AD584

With power applied to pins 8 and 4 and all other pins open the AD584 will produce a buffered nominal 10.0V output between pins 1 and 4 (see Figure 1). The stabilized output voltage may be reduced to 7.5V, 5.0V or 2.5V by connecting the programming pins as follows:

OUTPUT VOLTAGE	PIN PROGRAMMING
7.5V	Join the 2.5V and 5.0V pins (2) and (3).
5.0V	Connect the 5.0V pin (2) to the output pin (1).
2.5V	Connect the 2.5V pin (3) to the output pin (1).

The options shown above are available without the use of any additional components. Multiple outputs using only one AD584, are also possible by simply buffering each voltage programming pin with a unity-gain noninverting op amp.

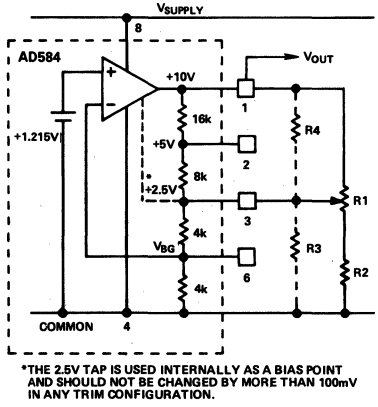

Figure 1. Variable Output Options

The AD584 can also be programmed over a wide range of output voltages, including voltages greater than 10V, by the addition of one or more external resistors. Figure 1 illustrates the general adjustment procedure, with approximate values given for the internal resistors of the AD584. The AD584 may be modeled as an op amp with a noninverting feedback connection, driven by a high stability 1.215 volt bandgap reference (see Figure 3 for schematic).

When the feedback ratio is adjusted with external resistors, the output amplifier can be made to multiply the reference voltage by almost any convenient amount, making popular outputs of 10.24V, 5.12V, 2.56V or 6.3V easy to obtain. The most general adjustment (which gives the greatest range and poorest resolution) uses R1 and R2 alone (see Figure 1). As R1 is adjusted to its upper limit the 2.5V pin 3 will be connected to the output, which will reduce to 2.5V. As R1 is adjusted to its lower limit, the output voltage will rise to a value limited by R2. For example, if R2 is about 6kΩ, the upper limit of the output range will be about 20V even for large values of R1. R2 should not be omitted; its value should be chosen to limit the output to a value which can be tolerated by the load circuits. If R2 is zero, adjusting R1 to its lower limit will result in a loss of control over the output voltage. If precision voltages are required to be set at levels other than the standard outputs, the 20% absolute tolerance in the internal resistor ladder must be accounted for.

Alternatively, the output voltage can be raised by loading the 2.5V tap with R3 alone. The output voltage can be lowered by connecting R4 alone. Either of these resistors can be a fixed resistor selected by test or an adjustable resistor. In all cases the resistors should have a low temperature coefficient to match the AD584 internal resistors, which have a negative T.C. less than 60ppm/°C. If both R3 and R4 are used, these resistors should have matched temperature coefficients.

When only small adjustments or trims are required, the circuit of Figure 2 offers better resolution over a limited trim range. The circuit can be programmed to 5.0V, 7.5V or 10V and adjusted by means of R1 over a range of about ±200mV. To trim the 2.5V output option, R2 (Figure 2) can be reconnected to the bandgap reference (pin 6). In this configuration, the adjustment should be limited to ±100mV in order to avoid affecting the performance of the AD584.

PRODUCT DESCRIPTION

The AD586 represents a major advance in the state-of-the-art in monolithic voltage references. Using a proprietary ion-implanted buried Zener diode and laser wafer trimming of high stability thin-film resistors, the AD586 provides outstanding performance at low cost.

The AD586 offers much higher performance than most other 5V references. Because the AD586 uses an industry standard pinout, many systems can be upgraded instantly with the AD586. The buried Zener approach to reference design provides lower noise and drift than bandgap voltage references. The AD586 offers a noise reduction pin which can be used to further reduce the noise level generated by the buried Zener.

The AD586 is recommended for use as a reference for 8-, 10-, 12-, 14- or 16-bit D/A converters which require an external precision reference. The device is also ideal for successive approximation or integrating A/D converters with up to 14 bits of accuracy and, in general, can offer better performance than the standard on-chip references.

The AD586J, K, L and M are specified for operation from 0 to +70°C, the AD586A and B are specified for −40°C to +85°C operation, and the AD586S and T are specified for −55°C to +125°C operation. The AD586J, K, L and M are available in an 8-pin plastic DIP. The AD586J, K, L, A and B are available in an 8-pin plastic surface mount small outline (SO) package. The AD586J, K, L, S and T are available in an 8-pin cerdip package.

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficients results in very low errors over temperature without the use of external components. The AD586M has a maximum deviation from 5.000V of ±2.45mV between 0 and +70°C, and the AD586T guarantees ±7.5mV maximum total error between −55°C and +125°C.
2. For applications requiring higher precision, an optional fine-trim connection is provided.
3. Any system using an industry standard pinout reference can be upgraded instantly with the AD586.
4. Output noise of the AD586 is very low, typically 4μV p-p. A noise reduction pin is provided for additional noise filtering using an external capacitor.
5. The AD586 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD586/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

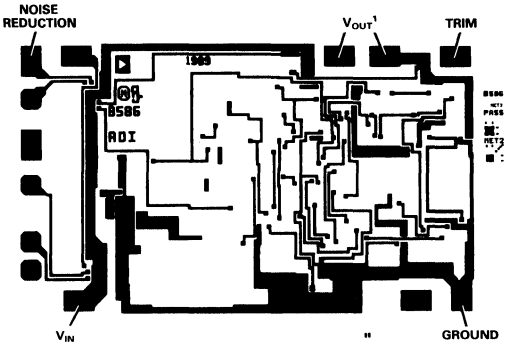
DIE SPECIFICATIONS

The following specifications are tested at the die level for AD586JCHIPS. These die are probed at 25°C only. (T_A = +25°C, V_{IN} = +15V unless otherwise specified)

Parameter	AD586JCHIPS Min	Typ	Max	Units
Output Voltage	4.980		5.020	V
Gain Adjustment	+6			%
	−2			%
Line Regulation				
10.8V < + V_{IN} < 36V			100	± μV/V
Load Regulation				
Sourcing 0 < I_{OUT} < 10mA			100	μV/mA
Sinking −10 < I_{OUT} < 0mA			400	μV/mA
Quiescent Current			3	mA
Short-Circuit Current-to-Ground			60	mA

DIE LAYOUT



Die Size: 0.096 × 0.061 Inches

NOTES
[1]Both V_{OUT} pads should be connected to the output.

Die Thickness: The standard thickness of Analog Devices Bipolar dice is 24 mils ± 2 mils.

Die Dimensions: The dimensions given have a tolerance of ± 2 mils.

Backing: The standard backside surface is silicon (not plated). Analog Devices does not recommend gold-backed dice for most applications.

Edges: A diamond saw is used to separate wafers into dice thus providing perpendicular edges half-way through the die. In contrast to scribed dice, this technique provides a more uniform die shape and size. The perpendicular edges facilitate handling (such as tweezer pick-up) while the uniform shape and size simplifies substrate design and die attach.

Top Surface: The standard top surface of the die is covered by a layer of glassivation. All areas are covered except bonding pads and scribe lines.

Surface Metalization: The metalization to Analog Devices bipolar dice is aluminum. Minimum thickness is 10,000Å.

Bonding Pads: All bonding pads have a minimum size of 4 mils by 4 mils. The passivation windows have 3.5 mils by 3.5 mils minimum.

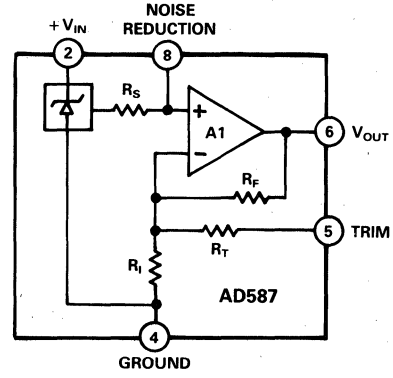
FUNCTIONAL BLOCK DIAGRAM



NOTE: PINS 1, 3 & 7 ARE INTERNAL TEST POINTS. NO CONNECTIONS TO THESE POINTS.

PRODUCT DESCRIPTION

The AD587 represents a major advance in the state-of-the-art in monolithic voltage references. Using a proprietary ion-implanted buried Zener diode and laser wafer trimming of high stability thin-film resistors, the AD587 provides outstanding performance at low cost.

The AD587 offers much higher performance than most other 10V references. Because the AD587 uses an industry standard pinout, many systems can be upgraded instantly with the AD587. The buried Zener approach to reference design provides lower noise and drift than band-gap voltage references. The AD587 offers a noise reduction pin which can be used to further reduce the noise level generated by the buried Zener.

The AD587 is recommended for use as a reference for 8-, 10-, 12-, 14- or 16-bit D/A converters which require an external precision reference. The device is also ideal for successive approximation or integrating A/D converters with up to 14 bits of accuracy and, in general, can offer better performance than the standard on-chip references.

The AD587J, K and L are specified for operation from 0 to +70°C, and the AD587S, T and U are specified for −55°C to +125°C operation. All grades are available in 8-pin cerdip. The J and K versions are also available in an 8-pin Small Outline IC (SOIC) package for surface mount applications, while the J, K and L grades also come in an 8-pin plastic package.

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficients results in very low errors over temperature without the use of external components. The AD587L has a maximum deviation from 10.000V of ±8.5mV between 0 and +70°C, and the AD587U guarantees ±14mV maximum total error between −55°C and +125°C.
2. For applications requiring higher precision, an optional fine-trim connection is provided.
3. Any system using an industry standard pinout 10 volt reference can be upgraded instantly with the AD587.
4. Output noise of the AD587 is very low, typically 4μV p-p. A noise reduction pin is provided for additional noise filtering using an external capacitor.
5. The AD587 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD587/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

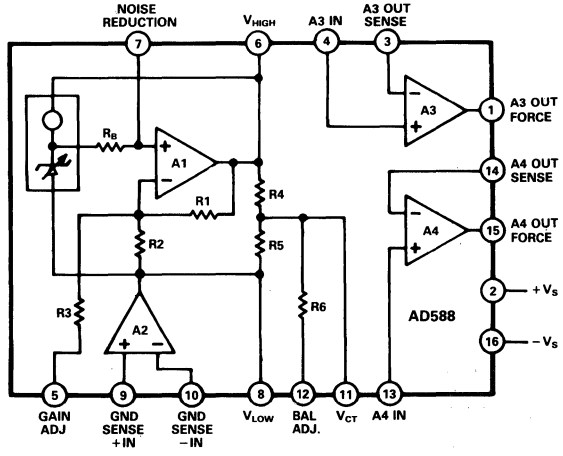
FUNCTIONAL BLOCK DIAGRAMS



PRODUCT DESCRIPTION

The AD588 represents a major advance in the state-of-the-art in monolithic voltage references. Low initial error and low temperature drift give the AD588 absolute accuracy performance previously not available in monolithic form. The AD588 uses a proprietary ion-implanted buried Zener diode, and laser-wafer-drift-trimming of high stability thin-film resistors to provide outstanding performance at low cost.

The AD588 includes the basic reference cell and three additional amplifiers which provide pin-programmable output ranges. The amplifiers are laser-trimmed for low offset and low drift to maintain the accuracy of the reference. The amplifiers are configured to allow Kelvin connections to the load and/or boosters for driving long lines or high-current loads, delivering the full accuracy of the AD588 where it is required in the application circuit.

The low initial error allows the AD588 to be used as a system reference in precision measurement applications requiring 12-bit absolute accuracy. In such systems, the AD588 can provide a known voltage for system calibration in software and the low drift allows compensation for the drift of other components in a system. Manual system calibration and the cost of periodic recalibration can therefore be eliminated. Furthermore, the mechanical instability of a trimming potentiometer and the potential for improper calibration can be eliminated by using the AD588 in conjunction autocalibration software.

The AD588 is available in seven versions. The AD588 JQ and KQ grades are packaged in a 16-pin cerdip and are specified for 0 to +70°C operation. AD588AD and BD grades are packaged in a 16-pin side-brazed ceramic DIP and are specified for the −25°C to +85°C industrial temperature range. The ceramic AD588SD and TD grades are specified for the full military/aerospace temperature range. For military surface mount applications, the AD588SE and TE grades will also be available in 20-pin LCC packages.

*Covered by Patent Number 4,644,253

PRODUCT HIGHLIGHTS

1. The AD588 offers 12-bit absolute accuracy without any user adjustments. Optional fine-trim connections are provided for applications requiring higher precision. The fine-trimming does not alter the operating conditions of the Zener or the buffer amplifiers and thus does not increase the temperature drift.
2. Output noise of the AD588 is very low – typically 6μV p-p. A pin is provided for additional noise filtering using an external capacitor.
3. A precision ±5V tracking mode with Kelvin output connections is available with no external components. Tracking error is less than one millivolt and a fine-trim is available for applications requiring exact symmetry between the +5V and −5V outputs.
4. Pin strapping capability allows configuration of a wide variety of outputs: ±5V, +5V & +10V, −5V & −10V dual outputs or +5V, −5V, +10V, −10V single outputs.
5. Extensive temperature testing at −55°C, −25°C, 0, +25°C, +50°C, +70°C, +85°C and +125°C ensures that the specified temperature coefficient is truly representative of device performance.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

ABSOLUTE MAXIMUM RATINGS*

$+V_S$ to $-V_S$	36V
Power Dissipation (+25°C)	
D Package	600mW
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10sec)	300°C
Package Thermal Resistance	
D (θ_{JA}/θ_{JC})	90/25°C/W
Output Protection: All outputs safe if shorted to ground	

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

APPLYING THE AD588

The AD588 can be configured to provide +10V and −10V reference outputs as shown in Figures 2a and 2c respectively. It can also be used to provide +5V, −5V or a ±5V tracking reference as shown in Figure 2b. Table I details the appropriate pin connections for each output range. In each case, pin 9 is connected to system ground and power is applied to pins 2 and 16.

The architecture of the AD588 provides ground sense and uncommitted output buffer amplifiers which offer the user a great deal of functional flexibility. The AD588 is specified and tested in the configurations shown in Figure 2. The user may choose to take advantage of the many other configuration options available with the AD588. However, performance in these configurations is not guaranteed to meet the extremely stringent data sheet specifications.

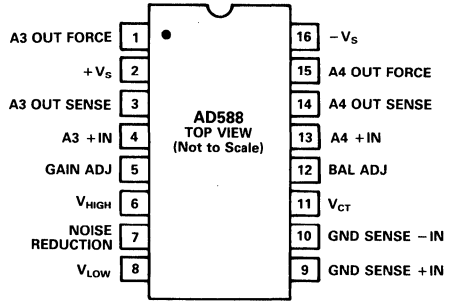
As indicated in Table I, a +5V buffered output can be provided using amplifier A4 in the +10V configuration (Figure 2a). A −5V buffered output can be provided using amplifier A3 in the −10V configuration (Figure 2c). Specifications are not guaranteed for the +5V or −5V outputs in these configurations. Performance will be similar to that specified for the +10V or −10V outputs.

As indicated in Table I, unbuffered outputs are available at pins 6, 8 and 11. Loading of these unbuffered outputs will impair circuit performance.

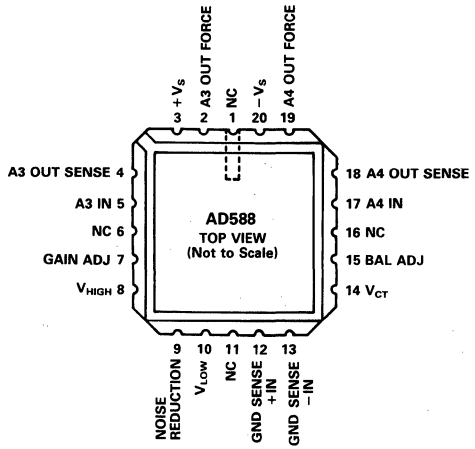
Amplifiers A3 and A4 can be used interchangeably. However, the AD588 is tested (and the specifications are guaranteed) with the amplifiers connected as indicated in Figure 2 and Table I.

PIN CONFIGURATIONS

DIP



LCC



NC = NO CONNECT

When either A3 or A4 is unused, its output force and sense pins should be connected and the input tied to ground.

Two outputs of the same voltage may be obtained by connecting both A3 and A4 to the appropriate unbuffered output on pin 6, 8 or 11. Performance in these dual output configurations will typically meet data sheet specifications.

Range	Connect Pin 10 to Pin:	Unbuffered[1] Output on Pins −10V	−5V	0V	+5V	+10V	Buffered Output Connections	Buffered Output on Pins −10V	−5V	0V	+5V	+10V

Two-Terminal IC 1.2V Reference

AD589

FEATURES

- Superior Replacement for Other 1.2V References
- Wide Operating Range: 50μA to 5mA
- Low Power: 60μW Total P_D at 50μA
- Low Temperature Coefficient:
  - 10ppm/°C max, 0 to +70°C (AD589M)
  - 25ppm/°C max, -55°C to +125°C (AD589U)
- Two-Terminal "Zener" Operation
- Low Output Impedance: 0.6Ω
- No Frequency Compensation Required
- Low Cost
- MIL-STD-883 Compliant Versions Available

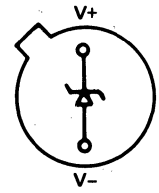
METAL CAN (H-02A)



BOTTOM VIEW

PRODUCT DESCRIPTION

The AD589 is a two-terminal, low cost, temperature compensated bandgap voltage reference which provides a fixed 1.23V output voltage for input currents between 50μA and 5.0mA.

The high stability of the AD589 is primarily dependent upon the matching and thermal tracking of the on-chip components. Analog Devices' precision bipolar processing and thin-film technology combine to provide excellent performance at low cost.

Additionally, the active circuit produces an output impedance ten times lower than typical low-TC zener diodes. This feature allows operation with no external components required to maintain full accuracy under changing load conditions.

The AD589 is available in seven versions. The AD589J, K, L and M grades are specified for 0 to +70°C operation, while the S, T and U grades are rated for the full -55°C to +125°C temperature range. All grades are available in a metal can (H-02A) package. The AD589J is also available in an 8-pin SOIC package.

PRODUCT HIGHLIGHTS

1. The AD589 is a two-terminal device which delivers a a constant reference voltage for a wide range of input current.
2. Output impedance of 0.6Ω and temperature coefficients as low as 10ppm/°C insure stable output voltage over a wide range of operating conditions.
3. The AD589 can be operated as a positive or negative reference. "Floating" operation is also possible.
4. The AD589 will operate with total current as low as 50μA (60μW total power dissipation), ideal for battery powered instrument applications.
5. The AD589 is an exact replacement for other 1.2V references, offering superior temperature performance and reduced sensitivity to capacitive loading.
6. The AD589 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD589/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]See following page for explanation of temperature coefficient measurement method.

[2]Optimum performance is obtained at currents below 500μA. For current operation below 200μA, stray shunt capacitances should be limited to 20pF or increased to 1μF. If strays can not be avoided, operation at 500μA and a shunt capacitor of at least 1000pF are recommended.

[3]H = Hermetic Metal Can; R = SOIC. For outline information see Package Information section.

Specifications shown in boldface are tested on all production units at final electrical test.

Specifications subject to change without notice.

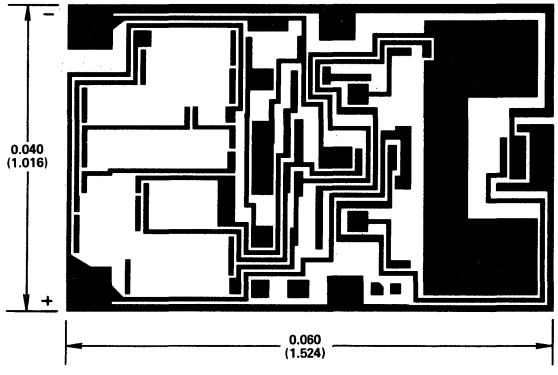
ABSOLUTE MAXIMUM RATINGS

Current 10mA
Reverse Current 10mA
Power Dissipation[1] 125mW
Storage Temperature Range . . . . . −65°C to +175°C
Operating Junction Temperature Range . −55°C to +150°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C

NOTE

[1]Absolute maximum power dissipation is limited by maximum current through the device. Maximum rating at elevated temperatures must be computed assuming $T_J \leq 150°C$, and $\theta_{JA} = 400 = C/W$.

AD589 CHIP DIMENSIONS AND PAD LAYOUT



THE AD589 IS AVAILABLE IN CHIP FORM WITH FULLY TESTED AND GUARANTEED SPECIFICATIONS. CONSULT FACTORY FOR AVAILABLE GRADES AND PRICING.

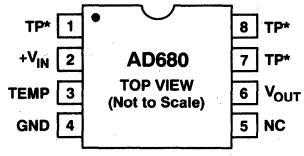
Low Power, Low Cost 2.5 V Reference

AD680*

FEATURES

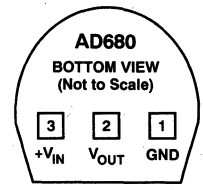
Low Quiescent Current: 250 μA max
Laser Trimmed to High Accuracy:
2.5 V ±5 mV max (AN, AR Grade)
Trimmed Temperature Coefficient:
20 ppm/°C max (AN, AR Grade)
Low Noise: 8 μV p–p from 0.1 to 10 Hz
250 nV/$\sqrt{Hz}$ Wideband
Temperature Output Pin (N, R Packages)
Available in Three Package Styles:
8-Pin Plastic DIP, 8-Pin SOIC and 3-Pin TO-92

CONNECTION DIAGRAMS



NC = NO CONNECT

*TP DENOTES FACTORY TEST POINT. NO CONNECTIONS SHOULD BE MADE TO THESE PINS.



PRODUCT DESCRIPTION

The AD680 is a bandgap voltage reference which provides a fixed 2.5 V output from inputs between 4.5 V and 36 V. The architecture of the AD680 enables the reference to be operated at a very low quiescent current while still realizing excellent dc characteristics and noise performance. Trimming of the high stability thin-film resistors is performed for initial accuracy and temperature coefficient, resulting in low errors over temperature.

The precision dc characteristics of the AD680 make it ideal for use as a reference for D/A converters which require an external precision reference. The device is also ideal for A/D converters and, in general, can offer better performance than the standard on-chip references.

Based upon the low quiescent current of the AD680, which rivals that of many incomplete two-terminal references, the AD680 is recommended for low power applications such as hand-held battery equipment.

A temperature output pin is provided on the 8-pin package versions of the AD680. The temperature output pin provides an output voltage that varies linearly with temperature and allows the AD680 to be configured as a temperature transducer while providing a stable 2.5 V output.

The AD680 is available in five grades. The AD680AN is specified for operation from −40°C to +85°C, while the AD680JN is specified for 0°C to +70°C operation. Both the AD680AN and AD680JN are available in 8-pin plastic DIP packages. The AD680AR is specified for operation from −40°C to +85°C, while the AD680JR is specified for 0°C to +70°C operation. Both are available in an 8-pin Small Outline IC (SOIC) package. The AD680JT is specified for 0°C to +70°C operation and is available in a 3-pin TO-92 package.

PRODUCT HIGHLIGHTS

1. The AD680 bandgap reference operates on a very low quiescent current which rivals that of many two-terminal references. This makes the complete, higher accuracy AD680 ideal for use in power sensitive applications.
2. Laser trimming of both initial accuracy and temperature coefficients results in low errors over temperature without the use of external components. The AD680AN and AD680AR have a maximum variation of 6.25 mV between −40°C and +85°C.
3. The AD680 noise is low, typically 8 μV p–p from 0.1 to 10 Hz. Spectral density is also low, typically 250 nV/$\sqrt{Hz}$.
4. The temperature output pin on the 8-pin package versions enables the AD680 to be configured as a temperature transducer.
5. Plastic DIP packaging provides machine insertability, while SOIC packaging provides surface mount capability. TO-92 packaging offers a cost effective alternative to two-terminal references, offering a complete solution in the same package in which two-terminal references are usually found.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

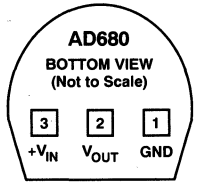

Figure 1. Connection Diagrams

THEORY OF OPERATION

Bandgap references are the high performance solution for low supply voltage operation. A typical precision bandgap will consist of a reference core and buffer amplifier. Based on a new, patented bandgap reference design (Figure 2), the AD680 merges the amplifier and the core bandgap function to produce a compact, complete precision reference. Central to the device is a high gain amplifier with an intentionally large Proportional To Absolute Temperature (PTAT) input offset. This offset is controlled by the area ratio of the amplifier input pair, Q1 and Q2, and is developed across resistor R1. Transistor Q12's base emitter voltage has a Complementary To Absolute Temperature (CTAT) characteristic. Resistor R2 and the parallel combination of R3 and R4 "multiply" the PTAT voltage across R1. Trimming resistors R3 and R4 to the proper ratio produces a temperature invariant 2.5 V at the output. The result is an accurate, stable output voltage accomplished with a minimum number of components.

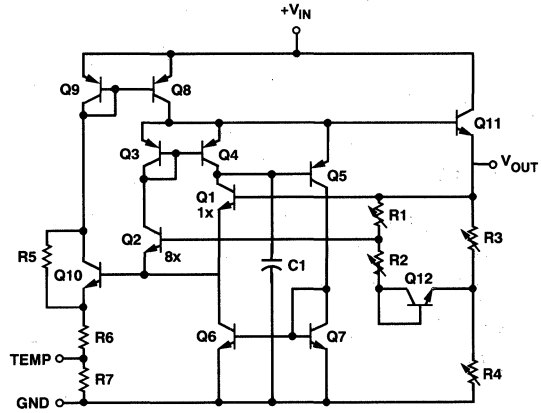

Figure 2. AD680 Schematic Diagram

An additional feature with this approach is the ability to minimize the noise while maintaining very low overall power dissipation for the entire circuit. Frequently it is difficult to independently control the dominant noise sources for bandgap references: bandgap transistor noise and resistor thermal noise. By properly choosing the operating currents of Q1 and Q2 and separately sizing R1, low wideband noise is realized while maintaining 1 mW typical power dissipation.

PRODUCT DESCRIPTION

The AD688 is a high precision ±10 V tracking reference. Low tracking error, low initial error and low temperature drift give the AD688 reference absolute ±10 V accuracy performance previously unavailable in monolithic form. The AD688 uses a proprietary ion-implanted buried Zener diode, and laser-wafer-drift-trimming of high stability thin-film resistors to provide outstanding performance at low cost.

The AD688 includes the basic reference cell and three additional amplifiers. The amplifiers are laser-trimmed for low offset and low drift and maintain the accuracy of the reference. The amplifiers are configured to allow Kelvin connections to the load and/or boosters for driving long lines or high current loads, delivering the full accuracy of the AD688 where it is required in the application circuit.

The low initial error allows the AD688 to be used as a system reference in precision measurement applications requiring 12-bit absolute accuracy. In such systems, the AD688 can provide a known voltage for system calibration and the cost of periodic recalibration can therefore be eliminated. Furthermore, the mechanical instability of a trimming potentiometer and the potential for improper calibration can be eliminated by using the AD688 and calibration software.

The AD688 is available in three versions. The AD688AQ and BQ grades are packaged in 16-pin cerdip (0.3″) packages and are specified for operation from −40°C to +85°C. The AD688SQ grade is specified for operation from −55°C to +125°C.

***Protected by Patent Number 4,644,253.**

PRODUCT HIGHLIGHTS

1. The AD688 offers precision tracking ±10 V Kelvin output connections with no external components. Tracking error is less than 1.5 mV and a fine-trim is available for applications requiring exact symmetry between the +10 V and −10 V outputs.
2. The AD688 offers 12-bit absolute accuracy without any user adjustments. Optional fine-trim connections are provided for applications requiring higher precision. The fine-trimming does not alter the operating conditions of the Zener or the buffer amplifiers and thus does not increase the temperature drift.
3. Output noise of the AD688 is low – typically 6 μV p–p. A pin is provided for broadband noise filtering using an external capacitor.
4. The AD688 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD688/883B data sheet for detailed specifications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

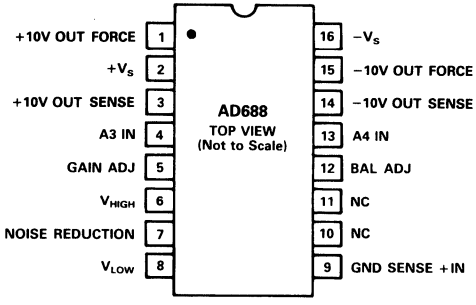
PIN CONFIGURATION



NC = NO CONNECT

NC PINS ARE USED AS TEST POINTS BY THE FACTORY. TO ENSURE PROPER OPERATION, DO NOT CONNECT ANYTHING TO THESE PINS.

THEORY OF OPERATION

The AD688 consists of a buried Zener diode reference, amplifiers and associated thin-film resistors as shown in the block diagram of Figure 1. The temperature compensation circuitry provides the device with a temperature coefficient of 1.5 ppm/°C or less.

Amplifier A1 performs several functions. A1 primarily acts to amplify the Zener voltage to the required 20 volts. In addition, A1 also provides for external adjustment of the 20 V output through Pin 5, the GAIN ADJUST. Using the bias compensation resistor between the Zener output and the noninverting input to A1, a capacitor can be added at the NOISE REDUCTION pin (Pin 7) to form a low pass filter and reduce the noise contribution of the Zener to the circuit. Two matched 12 kΩ nominal thin-film resistors (R4 and R5) divide the 20 V output in half.

Ground sensing for the circuit is provided by Amplifier A2. The noninverting input (Pin 9) senses the system ground and forces the midpoint of resistors R4 and R5 to be a virtual ground. Pin 12 (BALANCE ADJUST) can be used for fine adjustment of this midpoint transfer.

Amplifiers A3 and A4 are internally compensated and are used to buffer the voltages at Pins 6 and 8 as well as to provide a full Kelvin output. Thus, the AD688 has a full Kelvin capability by providing the means to sense a system ground and provide forced and sensed outputs referenced to that ground.

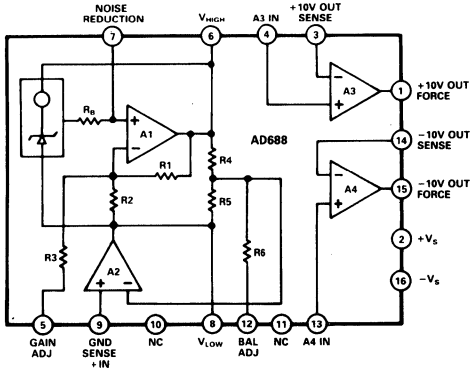


Figure 1. AD688 Functional Block Diagram

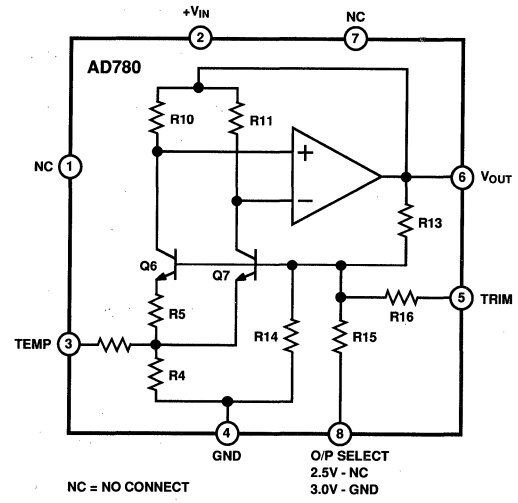
2.5 V/3.0 V High Precision Reference

AD780

FEATURES

Pin-Programmable 2.5 V or 3.0 V Output
Ultralow Drift: 3 ppm/°C max
High Accuracy: 2.5 V or 3.0 V ± 1 mV max
Low Noise: 100 nV/$\sqrt{\text{Hz}}$
Noise Reduction Capability
Low Quiescent Current: 1 mA max
Output Trim Capability
Plug-In Upgrade for Present References
Temperature Output Pin
Series or Shunt Mode Operation (±2.5 V, ±3.0 V)

FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD780 is an ultrahigh precision bandgap reference voltage which provides a 2.5 V or 3.0 V output from inputs between 4.0 V and 36 V. Low initial error and temperature drift combined with low output noise and the ability to drive any value of capacitance make the AD780 the ideal choice for enhancing the performance of high resolution ADCs and DACs and for any general purpose precision reference application. A unique low headroom design facilitates a 3.0 V output from a 5.0 V ± 10% input, providing a 20% boost to the dynamic range of an ADC, over performance with existing 2.5 V references.

The AD780 can be used to source or sink up to 10 mA and can be used in series or shunt mode, thus allowing positive or negative output voltages without external components. This makes it suitable for virtually any high performance reference application. Unlike some competing references, the AD780 has no "region of possible instability." The part is stable under all load conditions when a 1 μF bypass capacitor is used on the supply.

A temperature output pin is provided on the AD780. This provides an output voltage that varies linearly with temperature, allowing the AD780 to be configured as a temperature transducer while providing a stable 2.5 V or 3.0 V output.

The AD780 is a pin-compatible performance upgrade for the LT1019(A)-2.5 and the AD680. The latter is targeted toward low power applications.

The AD780 is available in two grades in plastic DIP, SOIC and cerdip packages. The AD780AN, AD780AR, AD780BN and AD780BR are specified for operation from −40°C to +85°C. The AD780SQ and AD780SQ/883B are specified for −55°C to +125°C operation.

PRODUCT HIGHLIGHTS

1. The AD780 provides a pin-programmable 2.5 V or 3.0 V output from a 4 V to 36 V input.
2. Laser trimming of both initial accuracy and temperature coefficients results in low errors over temperature without the use of external components. The AD780BN has a maximum variation of 0.8 mV from −40°C to +85°C.
3. For applications requiring even higher accuracy, an optional fine-trim connection is provided.
4. The AD780 noise is extremely low, typically 4 μV p-p from 0.1 Hz to 10 Hz and a wideband spectral noise density of typically 100 nV/$\sqrt{\text{Hz}}$. This can be further reduced if desired, by simply using two external capacitors.
5. The temperature output pin enables the AD780 to be configured as a temperature transducer while providing a stable output reference voltage.

NOTES

[1]Maximum output voltage drift is guaranteed for all packages.

[2]3.0 V mode typically adds 100 μA to the quiescent current. Also, Iq increases by 2 μA/V above an input voltage of 5 V.

[3]The long term stability specification is noncumulative. The drift in subsequent 1000 hr. periods is significantly lower than in the first 1000 hr. period.

[4]The operating temperature range is defined as the temperature extremes at which the device will still function. Parts may deviate from their specified performance outside their specified temperature range.

*Same as AD780AN/AR/SQ specification.

Specifications subject to change without notice.

CAUTION

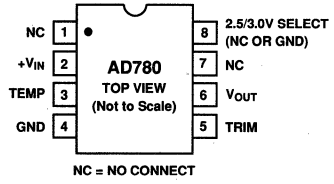
ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD780 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

ABSOLUTE MAXIMUM RATINGS*

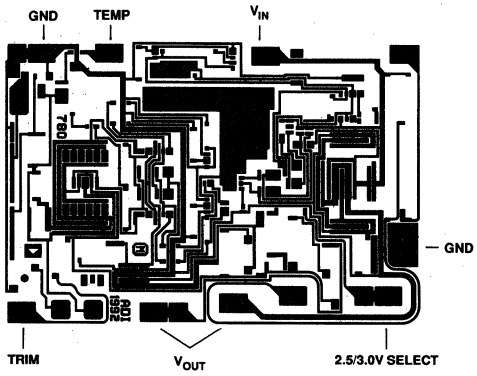
V_{IN} to Ground . . . . . 36 V
Trim Pin to Ground . . . . . 36 V
Temp Pin to Ground . . . . . 36 V
Power Dissipation (25°C) . . . . . 500 mW
Storage Temperature . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 sec) . . . . . 300°C
Output Protection: Output safe for indefinite short to ground and momentary short to V_{IN}.
ESD Classification . . . . . Class 1 (1000 V)

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions above those indicated in the operational specification is not implied. Exposure to absolute maximum specifications for extended periods may affect device reliability.

PIN CONFIGURATION
8-Pin Plastic DIP, SOIC and Cerdip Packages



DIE LAYOUT



NOTES
Both V_{OUT} pads should be connected to the output.
Die Thickness: The standard thickness of Analog Devices Bipolar dice is 24 mils ±2 mils.
Die Dimensions: The dimensions given have a tolerance of ±2 mils.
Backing: The standard backside surface is silicon (not plated). Analog Devices does not recommend gold-backed dice for most applications.
Edges: A diamond saw is used to separate wafers into dice thus providing perpendicular edges half-way through the die.

In contrast to scribed dice, this technique provides a more uniform die shape and size. The perpendicular edges facilitate handling (such as tweezer pick-up) while the uniform shape and size simplifies substrate design and die attach.
Top Surface: The standard top surface of the die is covered by a layer of glassivation. All areas are covered except bonding pads and scribe lines.
Surface Metalization: The metalization to Analog Devices bipolar dice is aluminum. Minimum thickness is 10,000Å.
Bonding Pads: All bonding pads have a minimum size of 4.0 mils by 6.0 mils. The passivation windows have a 3.6 mils by 5.6 mils minimum size.

ORDERING GUIDE

Model	Initial Error	Temperature Coefficient	Temperature Range	Package Option*
AD780AN	5 mV	7 ppm/°C	−40°C to +85°C	N-8
AD780AR	5 mV	7 ppm/°C	−40°C to +85°C	R-8

AD780SQ/883B	5 mV	20 ppm/°C	−55°C to +125°C	Q-8

*For outline information see Package Information section.

THEORY OF OPERATION

Bandgap references are the high performance solution for low supply voltage and low power voltage reference applications. In this technique a voltage with a positive temperature coefficient is combined with the negative coefficient of a transistor's Vbe to produce a constant *bandgap* voltage.

In the AD780, the bandgap cell contains two npn transistors (Q6 and Q7) which differ in emitter area by 12×. The difference in their Vbe's produces a PTAT current in R5. This in turn produces a PTAT voltage across R4, which when combined with the Vbe of Q7, produces a voltage Vbg that does not vary with temperature. Precision laser trimming of the resistors and other patented circuit techniques are used to further enhance the drift performance.

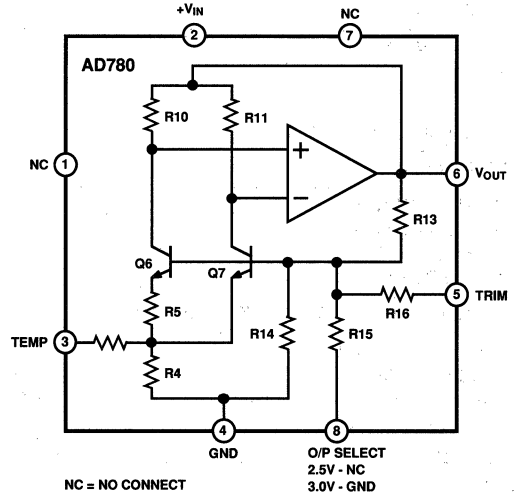

Figure 1. Schematic Diagram

The output voltage of the AD780 is determined by the configuration of resistors R13, R14 and R15 in the amplifier's feedback loop. This sets the output to either 2.5 V or 3.0 V depending on whether R15 (Pin 8) is grounded or not connected.

A unique feature of the AD780 is the low headroom design of the high gain amplifier which produces a precision 3 V output from an input voltage as low as 4.5 V (or 2.5 V from a 4.0 V input). The amplifier design also allows the part to work with $V_{IN} = V_{OUT}$ when current is forced into the output terminal. This allows the AD780 to work as a two terminal shunt regulator providing a −2.5 V or −3.0 V reference voltage output without external components.

The PTAT voltage is also used to provide the user with a thermometer output voltage (at Pin 3) which increases at a rate of approximately 2 mV/°C.

The AD780's NC Pin 7 is a 20 kΩ resistor to V+ which is used solely for production test purposes. Users who are currently using the LT1019 self-heater pin (Pin 7) must take into account the different load on the heater supply.

APPLYING THE AD780

The AD780 can be used without any external components to achieve specified performance. If power is supplied to Pin 2 and Pin 4 is grounded, Pin 6 provides a 2.5 V or 3.0 V output depending on whether Pin 8 is left unconnected or grounded.

A bypass capacitor of 1 μF (V_{IN} to GND) should be used if the load capacitance in the application is expected to be greater than 1 nF. The AD780 in 2.5 V mode typically draws 700 μA of Iq at 5 V. This increases by ~2 μA/V up to 36 V.

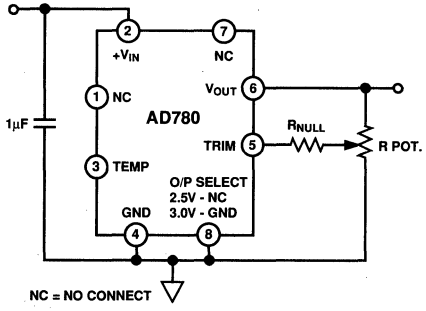

Figure 2. Optional Fine Trim Circuit

Initial error can be nulled using a single 25 kΩ potentiometer connected between V_{OUT}, Trim and GND. This is a coarse trim with an adjustment range of ±4% and is only included here for compatibility purposes with other references. A fine trim can be implemented by inserting a large value resistor (e.g. 1–5 MΩ) in series with the wiper of the potentiometer. See Figure 2 above. The trim range, expressed as a fraction of the output, is simply greater than or equal to 2.1 kΩ/R_{NULL} for either the 2.5 V or 3.0 V mode.

The external null resistor affects the overall temperature coefficient by a factor equal to the percentage of V_{OUT} nulled.

For example a 1 mV (.03%) shift in the output caused by the trim circuit, with a 100 ppm/°C null resistor will add less than 0.06 ppm/°C to the output drift (0.03% × 200 ppm/°C, since the resistors internal to the AD780 also have temperature coefficients of less than 100 ppm/°C).

NOISE PERFORMANCE

The impressive noise performance of the AD780 can be further improved if desired by the addition of two capacitors: a load capacitor C1 between the output and ground, and a compensation capacitor C2 between the TEMP pin and ground. Suitable values are shown in Figure 3.

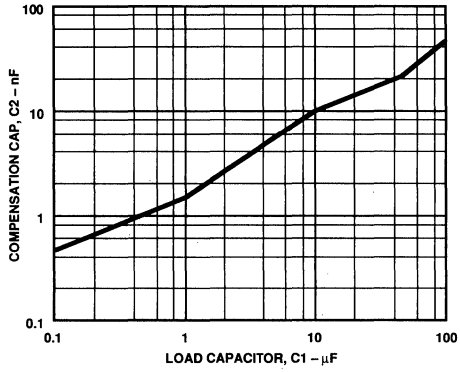

Figure 3. Compensation and Load Capacitor Combinations

C1 and C2 also improve the settling performance of the AD780 when subjected to load transients. The improvement in noise performance is shown in Figures 4, 5 and 6 following.

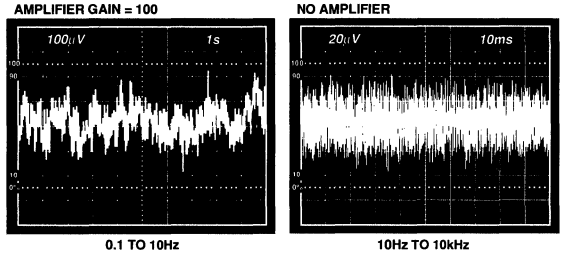

Figure 4. Stand-Alone Noise Performance

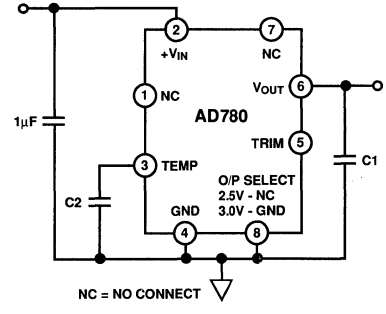

Figure 5. Noise Reduction Circuit

NOISE COMPARISON

The wideband noise performance of the AD780 can also be expressed in ppm. The typical performance with C1, C2 is 0.6 ppm and without external capacitors is 1.2 ppm.

This performance is respectively 7× and 3× lower than the specified performance of the LT1019.

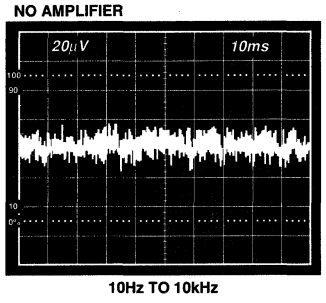

Figure 6. Reduced Noise Performance with C1 = 100 μF, C2 = 100 nF

TEMPERATURE PERFORMANCE

The AD780 provides superior performance over temperature by means of a combination of patented circuit design techniques, precision thin film resistors and drift trimming. Temperature performance is specified in terms of ppm/°C, but because of nonlinearity in the temperature characteristic, the Box-Test method is used to test and specify the part. The nonlinearity takes the form of the characteristic S-shaped curve shown in Figure 7. The Box-Test method forms a rectangular box around this curve, enclosing the maximum and minimum output voltages over the specified temperature range. The specified drift is equal to the slope of the diagonal of this box.

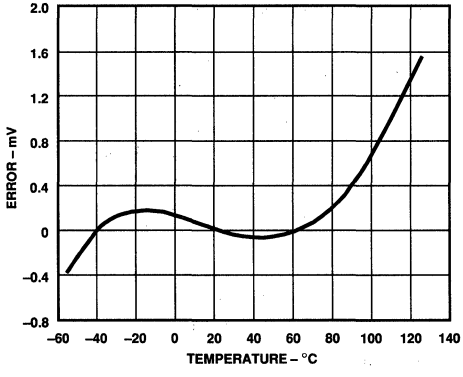

Figure 7. Typical AD780BN Temperature Drift

TEMPERATURE OUTPUT PIN

The AD780 provides a "TEMP" output (Pin 3) that varies linearly with temperature. This output can be used to monitor changes in system ambient temperature and to initiate calibration of the system if desired.

The voltage V_{TEMP} is 560 mV at 25°C, and the temperature coefficient is approximately 2 mV/°C. Figure 8 following shows the typical V_{TEMP} characteristic curve over temperature.

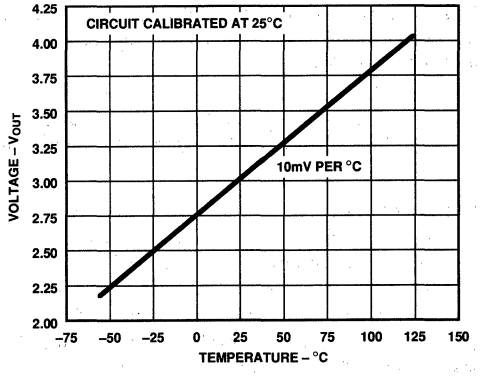

Figure 8. Temperature Pin Transfer Characteristic

Since the TEMP voltage is acquired from the bandgap core circuit, current pulled from this pin will have an effect on V_{OUT}. Care must be taken to buffer the TEMP output with a suitable op amp, e.g., an AD OP-07, AD820 or AD711 (all of which would result in less than a 100 μV change in V_{OUT}). The relationship between I_{TEMP} and V_{OUT} is as follows:

$$\Delta V_{OUT} = 5.8\ mV/\mu A \times I_{TEMP}\ (2.5\ V\ range)$$

or

$$\Delta V_{OUT} = 6.9\ mV/\mu A \times I_{TEMP}\ (3.0\ V\ range)$$

TEMPERATURE TRANSDUCER CIRCUIT

The circuit shown in Figure 9 is a temperature transducer which amplifies the TEMP output voltage by a gain of a little over 5 to provide a wider full scale output range. The trimpot can be used to adjust the output so it varies exactly by 10 mV/°C.

To minimize resistance changes with temperature, resistors with low temperature coefficients, such as metal film resistors should be used.

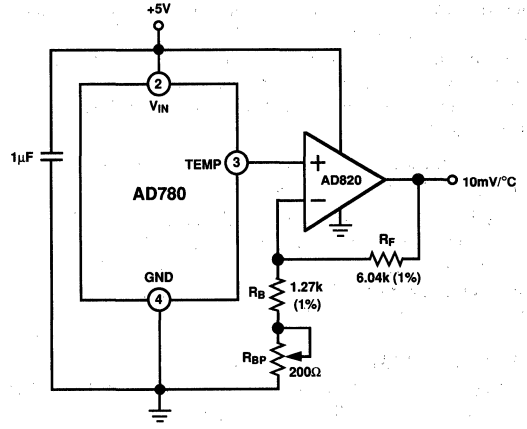

Figure 9. Differential Temperature Transducer

SUPPLY CURRENT OVER TEMPERATURE

The AD780's quiescent current will vary slightly over temperature and input supply range. The test limit is 1 mA over the industrial and 1.3 mA over the military temperature range. Typical performance with input voltage and temperature variation is shown in Figure 10 following.

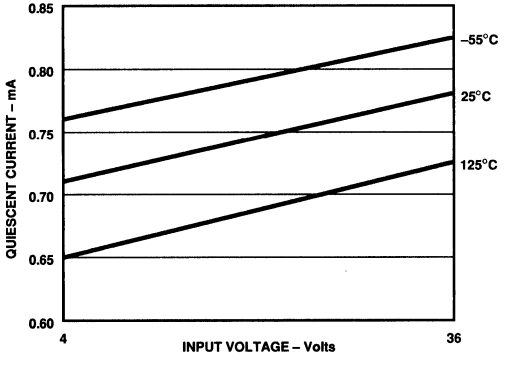

Figure 10. Typical Supply Current over Temperature

TURN-ON TIME

The time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. The two major factors that affect this are the active circuit settling time and the time for the thermal gradients on the chip to stabilize. Typical settling performance is shown in Figure 11 following. The AD780 settles to within 0.1% of its final value within 10 μs.

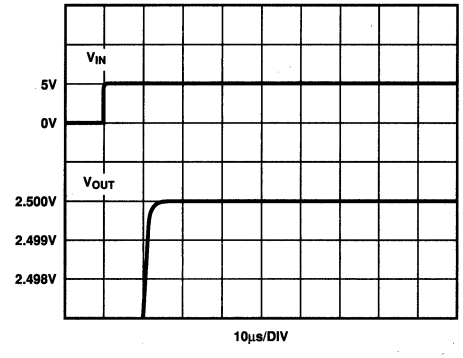

Figure 11. Turn-On Settling Time Performance

DYNAMIC PERFORMANCE

The output stage of the AD780 has been designed to provide superior static and dynamic load regulation.

Figure 12 shows the performance of the AD780 while driving a 0 mA to 10 mA load.

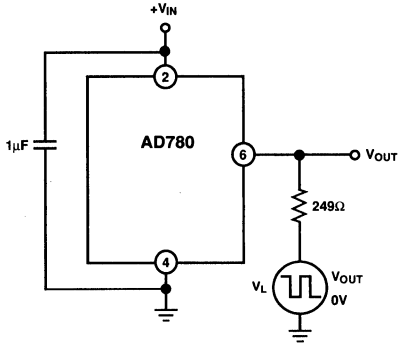

Figure 12a. Transient Resistive Load Test Circuit

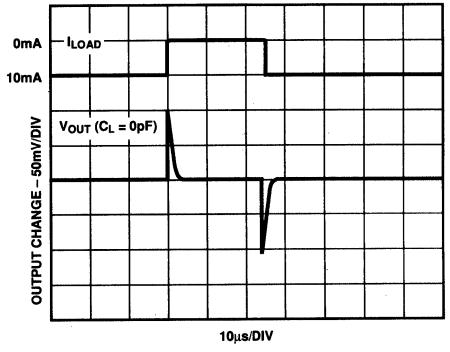

Figure 12b. Settling Under Transient Resistive Load

The dynamic load may be resistive and capacitive. For example the load may be connected via a long capacitive cable. Figure 13 following shows the performance of the AD780 driving a 1000 pF, 0 mA to 10 mA load.

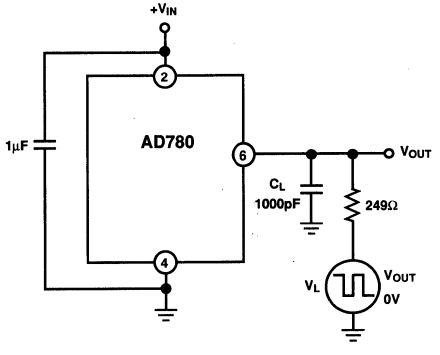

Figure 13a. Capacitive Load Transient Response Test Circuit

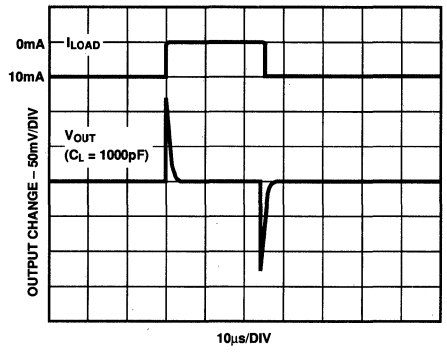

Figure 13b. Settling Under Dynamic Capacitive Load

LINE REGULATION

Line regulation is a measure of the change in output voltage due to a specified change in input voltage. It is intended to simulate worst case unregulated supply conditions and is measured in µV/V. Figure 14 shows typical performance with 4.0 V < V_{IN} < 15.0 V.

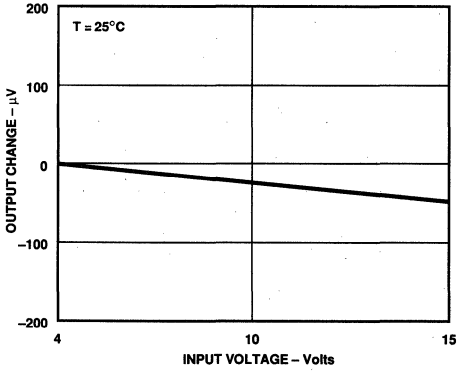

Figure 14. Output Voltage Change vs. Input Voltage

PRECISION REFERENCE FOR HIGH RESOLUTION +5 V DATA CONVERTERS

The AD780 is ideally suited to be the reference for most +5 V high resolution ADCs. The AD780 is stable under any capacitive load, it has superior dynamic load performance, and the 3.0 V output provides the converter with maximum dynamic range without requiring an additional and expensive buffer amplifier. One of the many ADCs that the AD780 is suited for is the AD7884, a 16-bit, high speed sampling ADC. (See Figure 15.) This part previously needed a precision 5.0 V reference, resistor divider and buffer amplifier to do this function.

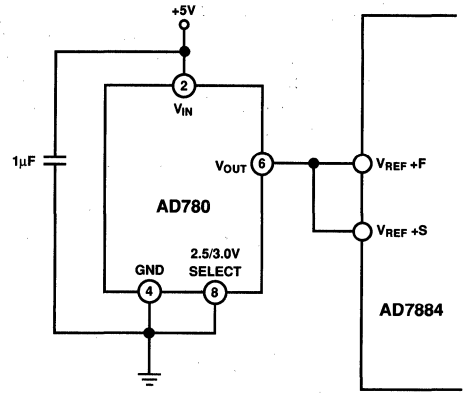

Figure 15. Precision 3.0 V Reference for the AD7884 16-Bit, High Speed ADC

The AD780 is also ideal for use with higher resolution converters such as the AD7710/AD7711/AD7712. (See Figure 16.) While these parts are specified with a 2.5 V internal reference, the AD780 in 3 V mode can be used to improve the absolute accuracy, temperature stability and dynamic range. It is shown following with the two optional noise reduction capacitors.

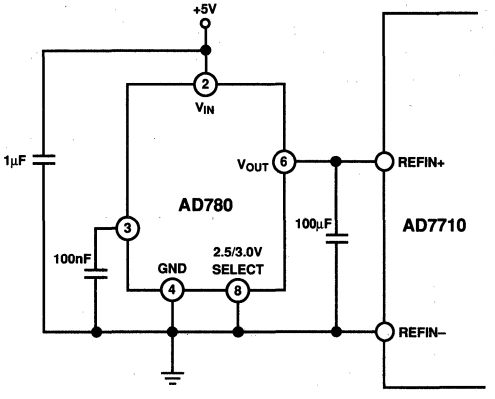

Figure 16. Precision 2.5 V or 3.0 V Reference for the AD7710 High Resolution, Sigma-Delta ADC

+4.5 V REFERENCE FROM +5 V SUPPLY

Some +5 V high resolution ADCs can accommodate reference voltages up to +4.5 V. The AD780 can be used to provide a precision +4.5 V reference voltage from a +5 V supply using the circuit shown following in Figure 17. This circuit will provide a regulated +4.5 V output from a supply voltage as low as +4.7 V. The high quality tantalum 10 µF capacitor in parallel with the ceramic 0.1 µF capacitor and the 3.9 Ω resistor ensure a low output impedance up to around 50 MHz.

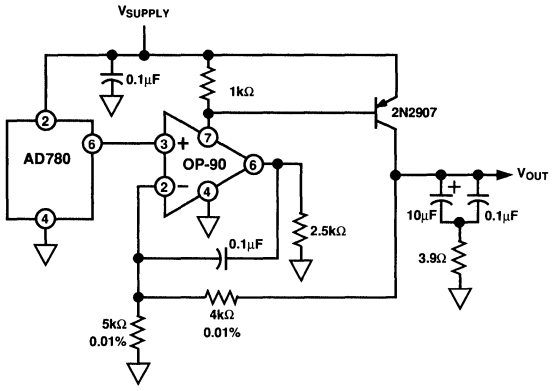

Figure 17. +4.5 V Reference from a Single +5 V Supply

NEGATIVE (−2.5 V OR −3.0 V) REFERENCE

The AD780 can produce a negative output voltage in shunt mode, simply by connecting the input and output to ground and connecting the AD780's GND pin to a negative supply via a bias resistor as shown in Figure 18.

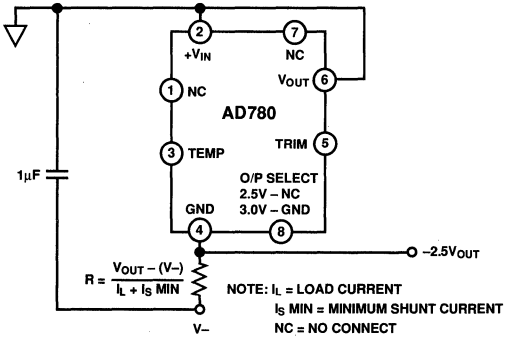

Figure 18. Negative (−2.5 V) Shunt Mode Reference

A precise −2.5 V (or −3.0 V) reference capable of supplying up to 100 mA to a load can be implemented with the AD780 in series mode using the bootstrap circuit following.

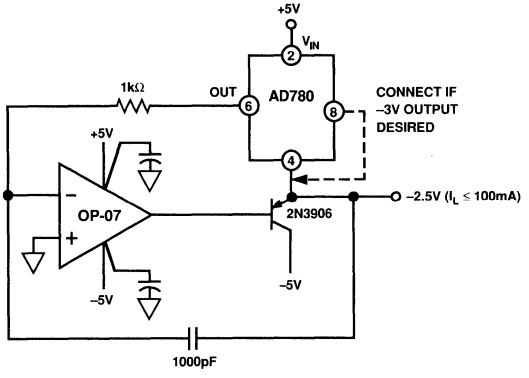

Figure 19. −2.5 V High Load Current Reference

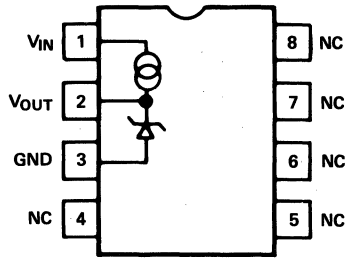
Low Cost, Precision 2.5V IC References

AD1403/AD1403A*

FEATURES

Improved, Lower Cost, Replacements for Standard 1403, 1403A
3-Terminal Device: Voltage In/Voltage Out
Laser Trimmed to High Accuracy: 2.500V ±10mV (AD1403A)
Excellent Temperature Stability: 25ppm/°C (AD1403A)
Low Quiescent Current: 1.5mA max
10mA Current Output Capability
Low Cost
Convenient Mini-DIP Package

FUNCTIONAL BLOCK DIAGRAM



8 PIN MINI-DIP

PRODUCT DESCRIPTION

The AD1403 and AD1403A are improved three-terminal, low cost, temperature compensated, bandgap voltage references that provide a fixed 2.5V output voltage for inputs between 4.5V and 40V. A unique combination of advanced circuit design and laser-wafer-trimmed thin-film resistors provides the AD1403/AD1403A with an initial tolerance of ±10mV and a temperature stability of better than 25ppm/°C. In addition, the low quiescent current drain of 1.5mA (max) offers a clear advantage over classical Zener techniques.

The AD1403 or AD1403A is recommended as a stable reference for all 8-, 10- and 12-bit D-to-A converters that require an external reference. In addition, the wide input range of the AD1403/AD1403A allows operation with 5 volt logic supplies, making these devices ideal for digital panel meter applications and when only a single logic supply is available.

The AD1403 and AD1403A are specified for operation over the 0 to +70°C temperature range. The AD580 series of 2.5 volt precision IC references is recommended for applications where operation over the −55°C to +125°C range is required.

PRODUCT HIGHLIGHTS

1. The AD1403A offers improved initial tolerance over the industry-standard 1403A: ±10mV versus ±25mV at a lower cost.
2. The three-terminal voltage in/voltage out operation of the AD1403/AD1403A provides a regulated output voltage without any external components.
3. The AD1403/AD1403A provides a stable 2.5V output voltage for input voltages between 4.5V and 40V making these devices ideal for systems that contain a single logic supply.
4. Thin film resistor technology and tightly controlled bipolar processing provide the AD1403A with temperature stabilities of 25ppm/°C.
5. The low 1.5mA maximum quiescent current drain of the AD1403 and AD1403A makes them ideal for CMOS and other low power applications.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

+2 V to +16.5 V Operating Range
Low Battery Detector ADM666
No Overshoot on Power-Up

APPLICATIONS
Handheld Instruments
LCD Display Systems
Pagers
Remote Data Acquisition

GENERAL DESCRIPTION

The ADM663/ADM666 are precision voltage regulators featuring a maximum quiescent current of 12 μA. They can be used to give a fixed +5 V output with no additional external components or can be adjusted from 1.3 V to 16 V using two external resistors. Fixed or adjustable operation is automatically selected via the V_{SET} input. The low quiescent current makes these devices especially suitable for battery powered systems. The input voltage range is 2 V to 16.5 V and an output current up to 40 mA is provided. The ADM663 can directly drive an external pass transistor for currents in excess of 40 mA. Additional features include current limiting and low power shutdown. Thermal shutdown circuitry is also included for additional safety.

The ADM666 features additional low battery monitoring circuitry to detect for low battery voltages.

The ADM663/ADM666 are pin-compatible replacements for the MAX663/666. Both are available in 8-pin DIP and in narrow surface mount (SOIC) packages.

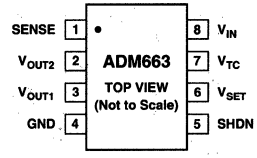
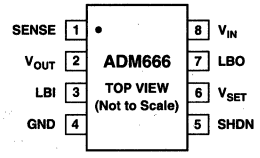
DIP & SOIC PIN CONFIGURATIONS





PIN FUNCTION DESCRIPTION

Mnemonic	Function
$V_{OUT(1)\ (2)}$	Voltage Regulator Output(s)
V_{IN}	Voltage Regulator Input
SENSE	Current Limit Sense Input. (Referenced to $V_{OUT(2)}$.) If not used it should be connected to $V_{OUT(2)}$
GND	Ground Pin. Must be connected to 0 V
LBI	Low Battery Detect Input. Compared with 1.3 V
LBO	Low Battery Detect Output. Open Drain Output
SHDN	Digital Input. May be used to disable the device so that the power consumption is minimized
V_{SET}	Voltage Setting Input. Connect to GND for +5 V output or connect to resistive divider for adjustable output
V_{TC}	Temperature-Proportional Voltage for negative TC Output

GENERAL INFORMATION

The ADM663/ADM666 contains a micropower bandgap reference voltage source, an error amplifier A1, two comparators C1, C2 and a series pass output transistor. A P-channel FET and an NPN transistor are used on the ADM663 while the ADM666 uses an NPN output transistor.

CIRCUIT DESCRIPTION

The internal bandgap reference is trimmed to 1.3 V ± 30 mV. This is used as a reference input to the error amplifier A1. The feedback signal from the regulator output is supplied to the other input by an on-chip voltage divider or by two external resistors. When V_{SET} is at ground, the internal divider provides the error amplifier's feedback signal giving a +5 V output. When V_{SET} is at more than 50 mV above ground, the error amplifier's input is switched directly to the V_{SET} pin, and external resistors are used to set the output voltage. The external resistors are selected so that the desired output voltage gives 1.3 V at V_{SET}.

Comparator C1 monitors the output current via the SENSE input. This input, referenced to $V_{OUT(2)}$, monitors the voltage drop across a load sense resistor. If the voltage drop exceeds 0.5 V, then the error amplifier A_1 is disabled and the output current is limited.

The ADM663 has an additional amplifier, A2, which provides a temperature-proportional output, V_{TC}. If this is summed into the inverting input of the error amplifier, a negative temperature coefficient results at the output. This is useful when powering liquid crystal displays over wide temperature ranges.

The ADM666 has an additional comparator, C3 which compares the voltage on the Low Battery Input, LBI, pin to the internal +1.3 V reference. The output from the comparator drives an open drain FET connected to the Low Battery Output pin, LBO. The Low Battery Threshold may be set using a suitable voltage divider connected to LBI. When the voltage on LBI falls below 1.3 V, the open drain output LBO is pulled low.

Both the ADM663 and the ADM666 contain a shutdown (SHDN) input which can be used to disable the error amplifier and hence the voltage output. The quiescent current in shutdown is less than 12 µA.

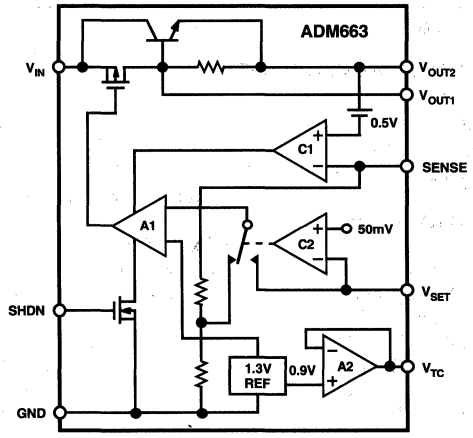


Figure 1. ADM663 Functional Block Diagram

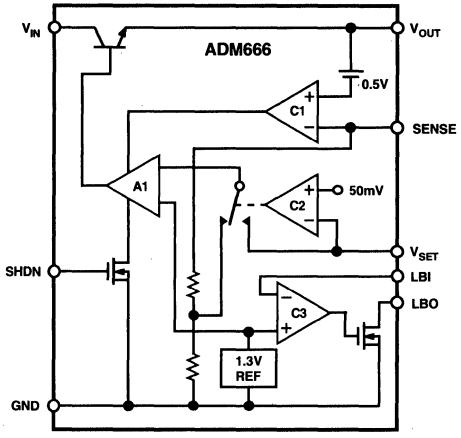

Figure 2. ADM666 Functional Block Diagram

Circuit Configurations

For a fixed +5 V output the V_{SET} input is grounded and no external resistors are necessary. This basic configuration is shown in Figure 3. Current limiting is not being utilized so the SENSE input is connected to $V_{OUT(2)}$. The input voltage can range from +6 V to +16 V and output currents up to 40 mA are available provided that the maximum package power dissipation is not exceeded.

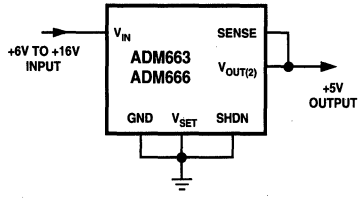

Figure 3. ADM663/ADM666 Fixed +5 V Output

Output Voltage Setting

If V_{SET} is not connected to GND, the output voltage is set according to the following equation.

$$V_{OUT} = V_{SET} \times \frac{R1 + R2}{R1} \quad where\ V_{SET} = 1.30\,V$$

The resistor values may be selected by firstly choosing a value for R1 and then selecting R2 according to the following equation.

$$R2 = R1 \times \left(\frac{V_{OUT}}{1.30} - 1 \right)$$

The input leakage current on V_{SET} is 10 nA maximum. This allows large resistor values to be chosen for R1 and R2 with little degradation in accuracy. For example, a 1 MΩ resistor may be selected for R1 and then R2 may be calculated accordingly. The tolerance on V_{SET} is guaranteed at less than ±30 mV so in most applications, fixed resistors will be suitable.

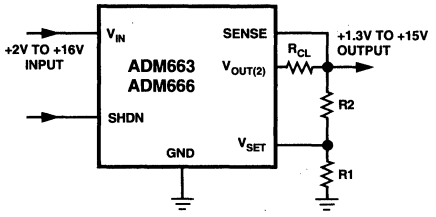

Figure 4. ADM663/ADM666 Adjustable Output

Current Limiting

Current limiting may be achieved by using an external current sense resistor in series with $V_{OUT(2)}$. When the voltage across the sense resistor exceeds the internal 0.5 V threshold, current limiting is activated. The sense resistor is therefore chosen such that the voltage across it will be 0.5 V when the desired current limit is reached.

$$R_{CL} = \frac{0.5}{I_{CL}}$$

where R_{CL} is the current sense resistor, I_{CL} is the maximum current limit.

The value chosen for R_{CL} should also ensure that the current is limited to less than the 50 mA absolute maximum rating and also that the power dissipation will also be within the package maximum ratings.

If current limiting is employed, there will be an additional voltage drop across the sense resistor which must be considered when determining the regulators dropout voltage.

If current limiting is not used, the SENSE input should be connected to $V_{OUT(2)}$.

Shutdown Input (SHDN)

The SHDN input allows the regulator to be switched off with a logic level signal. This will disable the output and reduce the current drain to a low quiescent (12 µA maximum) current. This is very useful for low power applications. The SHDN input should be driven with a CMOS logic level signal since the input threshold is 0.3 V. In TTL systems, an open collector driver with a pull-up resistor may be used.

If the shutdown function is not being used, then SHDN should be connected to GND.

Low Supply or Low Battery Detection

The ADM666 contains on-chip circuitry for low power supply or battery detection. If the voltage on the LBI pin falls below the internal 1.3 V reference, then the open drain output LBO will go low. The low threshold voltage may be set to any voltage above 1.3 V by appropriate resistor divider selection.

$$R3 = R4 \times \left(\frac{V_{BATT}}{1.30} - 1 \right)$$

where R3 and R4 are the resistive divider resistors and V_{BATT} is the desired low voltage threshold.

Since the LBI input leakage current is less than 10 nA, large values may be selected for R3 and R4 in order to minimize loading. For example, a 6 V low threshold, may be set using 10 MΩ for R3 and 2.7 MΩ for R4.

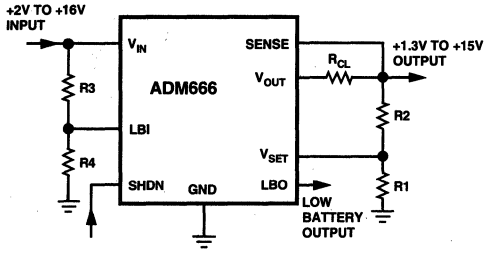

Figure 5. ADM666 Adjustable Output with Low Battery Detection

High Current Operation

The ADM663 contains an additional output, V_{OUT1}, suitable for directly driving the base of an external NPN transistor. Figure 6 shows a configuration which can be used to provide +5 V with boosted current drive. A 1 Ω current sensing resistor limits the current at 0.5 A.

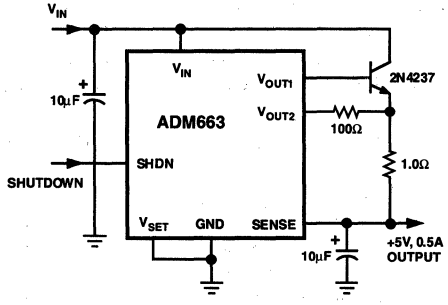

Figure 6. ADM663 Boosted Output Current (0.5 A)

Temperature Proportional Output

The ADM663 contains a V_{TC} output with a positive temperature coefficient of +2.5 mV/°C. This may be connected to the summing junction of the error amplifier (V_{SET}) through a resistor resulting in a negative temperature coefficient at the output of the regulator.

This is especially useful in multiplexed LCD displays to compensate for the inherent negative temperature coefficient of the LCD threshold. At 25°C the voltage at the VTC output is typically 0.9 V. The equations for setting both the output voltage and the tempco are given below. If this function is not being used, then V_{TC} should be left unconnected.

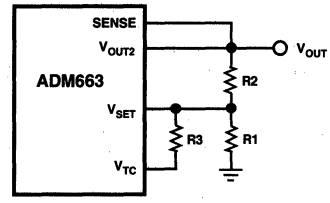

Figure 7. ADM663 Temperature Proportional Output

$$V_{OUT} = V_{SET} \times \left(1 + \frac{R2}{R1}\right) + \frac{R2}{R3} \times \left(V_{SET} - V_{TC}\right)$$

$$TCV_{OUT} = \frac{-R2}{R3} \times TVC_{TC}$$

where $V_{SET} = +1.3V$, $V_{TC} = +0.9V$, $TCV_{TC} = +2.5\,mV/°C$

APPLICATION HINTS

Input-Output (Dropout Voltage)

A regulator's minimum input-output differential or dropout voltage determines the lowest input voltage for a particular output voltage. The ADM663/ADM666 dropout voltage is 0.8 V at its rated output current. For example when used as a fixed +5 V regulator the minimum input voltage is +5.8 V. At lower output currents, (I_{OUT} < 5 mA), on the ADM663, V_{OUT1} may be used as the output driver in order to achieve lower dropout voltages. Please refer to Figure 9. In this case the dropout voltage depends on the voltage drop across the internal FET transistor. This may be calculated by multiplying the FET's saturation resistance by the output current. As the current limit circuitry is referenced to V_{OUT2}, V_{OUT2} should be connected to V_{OUT1}. For high current operation V_{OUT2} should be used alone and V_{OUT1} left unconnected.

Bypass Capacitors

The high frequency performance of the ADM663/ADM666 may be improved by decoupling the output using a filter capacitor. A capacitor value of 10 µF is suitable.

An input capacitor helps reduce noise and improves dynamic performance. A suitable input capacitor of 0.1 µF or greater may be used.

Tri-Mode: +3.3 V, +5 V, Adjustable Micropower Linear Voltage Regulators

ADM663A/ADM666A*

FEATURES

Tri-Mode Operation
3.3 V, 5 V Fixed or +1.3 V to +16 V Adjustable
Low Power CMOS: 9 μA max Quiescent Current
High Current 100 mA Output
Low Dropout Voltage
Upgrade for ADM663/ADM666
"Small" 0.1 μF Output Capacitor (0805 Style)
+2 V to +16.5 V Operating Range
Low Battery Detector ADM666A
No Overshoot on Power-Up
Thermal Shutdown

APPLICATIONS

Handheld Instruments
LCD Display Systems
Pagers
Battery Operated Equipment

GENERAL DESCRIPTION

The ADM663A/ADM666A are precision linear voltage regulators featuring a maximum quiescent current of 9 μA. They can be used to give a fixed +3.3 V or +5 V output with no additional external components or can be adjusted from 1.3 V to 16 V using two external resistors. Fixed or adjustable operation is automatically selected via the V_{SET} input. The low quiescent current makes these devices especially suitable for battery powered systems. The input voltage range is 2 V to 16.5 V, and an output current up to 100 mA is provided. Current limiting may be set using a single external resistor. For additional safety, an internal thermal shutdown circuit monitors the internal die temperature.

The ADM666A features additional low battery monitoring circuitry to detect for low battery voltages.

The ADM663A/ADM666A are pin compatible enhancements for the ADM663/ADM666. Improvements include an additional 3.3 V output range, higher output current, and operation with a small output capacitor.

The ADM663A/ADM666A are available in an 8-pin DIP and narrow surface mount (SOIC) packages.

TERMINOLOGY

Dropout Voltage: The input/output voltage differential at which the regulator no longer maintains regulation against further reductions in input voltage. It is measured when the output decreases 100 mV from its nominal value. The nominal value is the measured value with $V_{IN} = V_{OUT} + 2$ V.

Line Regulation: The change in output voltage as a result of a change in the input voltage. It is specified as a percentage change in output voltage for an input voltage change.

$$Line\ Reg = \frac{\frac{\Delta V_{OUT}}{V_{OUT}}(100)}{\Delta V_{IN}}$$

Load Regulation: The change in output voltage for a change in output current.

$$Load\ Reg\ (\Omega) = \frac{\Delta V_{OUT}}{\Delta I_{OUT}}$$

Quiescent Current: The input bias current which flows when the regulator output is unloaded or when the regulator is in shutdown.

Sense Input Threshold: Current limit sense voltage. This is the voltage (referenced to $V_{OUT(2)}$) at which current limiting occurs.

Input-Output Saturation Resistance (ADM663A): This is a measure of the internal MOS transistor effective resistance in series with V_{OUT1}. The minimum input-output voltage differential at low currents may be calculated by multiplying the load current by the saturation resistance.

Thermal Limiting: This feature monitors the internal die temperature and disables the output when an internal temperature of 125°C is reached.

Maximum Power Dissipation: The maximum total device dissipation for which the regulator will continue to operate within specifications.

GENERAL INFORMATION

The ADM663A/ADM666A contains a micropower bandgap reference voltage source; an error amplifier, A1; three comparators, C1, C2, C3, and a series pass output transistor. A P-channel FET and an NPN transistor are used on the ADM663A while the ADM666A uses an NPN output transistor.

CIRCUIT DESCRIPTION

The internal bandgap reference is trimmed to 1.3 V ± 30 mV. This is used as a reference input to the error amplifier A1. The feedback signal from the regulator output is supplied to the other input by an on-chip voltage divider or by two external resistors. When V_{SET} is at ground, the internal divider tap between R1 and R2, provides the error amplifier's feedback signal giving a +5 V output. When V_{SET} is at V_{IN}, the internal divider tap between R2 and R3 provides the error amplifier's feedback signal giving a +3.3 V output. When V_{SET} is at more than 50 mV above ground and less than 50 mV below V_{IN}, the error amplifier's input is switched directly to the V_{SET} pin, and external resistors are used to set the output voltage. The external resistors are selected so that the desired output voltage gives 1.3 V at V_{SET}.

Comparator C1 monitors the output current via the SENSE input. This input, referenced to $V_{OUT(2)}$, monitors the voltage drop across a load sense resistor. If the voltage drop exceeds 0.5 V, then the error amplifier A1 is disabled and the output current is limited.

The ADM663A has an additional amplifier, A2, which provides a temperature proportional output, V_{TC}. If this is summed into the inverting input of the error amplifier, a negative temperature coefficient results at the output. This is useful when powering liquid crystal displays over wide temperature ranges.

The ADM666A has an additional comparator, C4, that compares the voltage on the low battery input, LBI, pin to the internal +1.3 V reference. The output from the comparator drives an open drain FET connected to the low battery output pin, LBO. The low battery threshold may be set using a suitable voltage divider connected to LBI. When the voltage on LBI falls below 1.3 V, the open drain output LBO is pulled low.

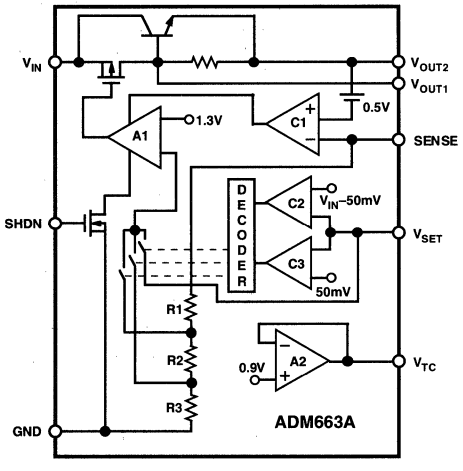

Figure 1. ADM663A Functional Block Diagram

Both the ADM663A and the ADM666A contain a shutdown (SHDN) input that can be used to disable the error amplifier and hence the voltage output. The power consumption in shutdown reduces to less than 9 µA.

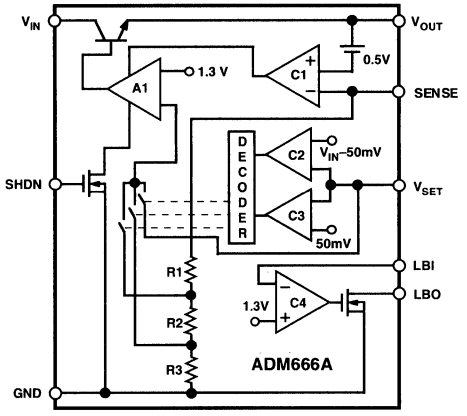

Figure 2. ADM666A Functional Block Diagram

Circuit Configurations

For a fixed +5 V output the V_{SET} input is grounded and no external resistors are necessary. This basic configuration is shown in Figure 3. For a fixed +3.3 V output, the V_{SET} input is connected to V_{IN} as shown in Figure 4. Current limiting is not being utilized so the SENSE input is connected to $V_{OUT(2)}$.

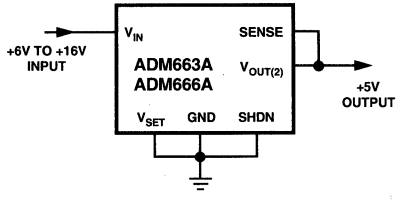

Figure 3. A Fixed +5 V Output

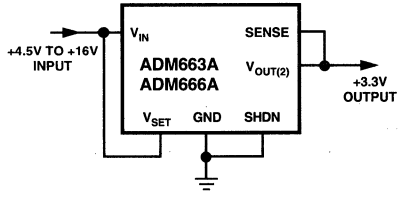

Figure 4. A Fixed +3.3 V Output

Output Voltage Setting

If V_{SET} is not connected to GND or to V_{IN}, the output voltage is set according to the following equation:

$$V_{OUT} = V_{SET} \times \frac{(R1 + R2)}{R1}$$

where V_{SET} = 1.30 V.

The resistor values may be selected by first choosing a value for R1 and then selecting R2 according to the following equation:

$$R2 = R1 \times \left(\frac{V_{OUT}}{1.30} - 1 \right)$$

The input leakage current on V_{SET} is 10 nA maximum. This allows large resistor values to be chosen for R1 and R2 with little degradation in accuracy. For example, a 1 MΩ resistor may be selected for R1, and then R2 may be calculated accordingly. The tolerance on V_{SET} is guaranteed at less than ±30 mV so in most applications, fixed resistors will be suitable.

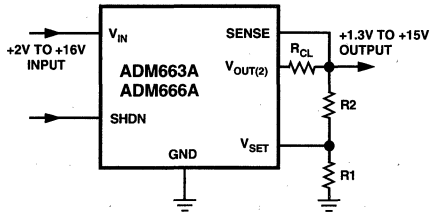

Figure 5. Adjustable Output

Table I. Output Voltage Selection

V_{SET}	V_{OUT}
GND	+5 V
V_{IN}	+3 V
R1/R2	ADJ

Current Limiting

Current limiting may be achieved by using an external current sense resistor in series with $V_{OUT(2)}$. When the voltage across the sense resistor exceeds the internal 0.5 V threshold, current limiting is activated. The sense resistor is therefore chosen such that the voltage across it will be 0.5 V when the desired current limit is reached.

$$R_{CL} = \frac{0.5}{I_{CL}}$$

where R_{CL} is the current sense resistor, I_{CL} is the maximum current limit.

The value chosen for R_{CL} should also ensure that the current is limited to less than the 100 mA absolute maximum rating and also that the power dissipation will also be within the package maximum ratings.

If current limiting is employed, there will be an additional voltage drop across the sense resistor that must be considered when determining the regulators dropout voltage.

If current limiting is not used, the SENSE input should be connected to $V_{OUT(2)}$.

Shutdown Input (SHDN)

The SHDN input allows the regulator to be turned off with a logic level signal. This will disable the output and reduce the current drain to a low quiescent (9 µA maximum) current. This is very useful for low power applications. The SHDN input should be driven with a CMOS logic level signal since the input threshold is 0.3 V. In TTL systems, an open collector driver with a pull-up resistor may be used.

If the shutdown function is not being used, then it should be connected to GND.

Low Supply or Low Battery Detection

The ADM666A contains on-chip circuitry for low power supply or battery detection. If the voltage on the LBI pin falls below the internal 1.3 V reference, then the open drain output LBO will go low. The low threshold voltage may be set to any voltage above 1.3 V by appropriate resistor divider selection.

$$R3 = R4 \left(\frac{V_{BATT}}{1.3\,V} - 1 \right)$$

where R3 and R4 are the resistive divider resistors and V_{BATT} is the desired low voltage threshold.

Since the LBI input leakage current is less than 10 nA, large values may be selected for R3 and R4 in order to minimize loading. For example, a 6 V low threshold may be set using 10 MΩ for R3 and 2.7 M Ω for R4.

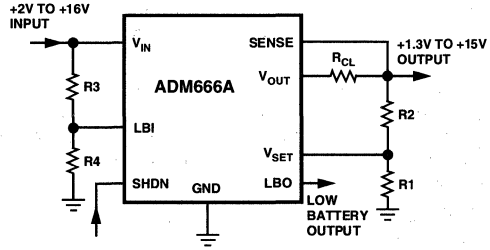

Figure 6. ADM666A Adjustable Output with Low Battery Detection

High Current Operation

The ADM663A contains an additional output, V_{OUT1}, suitable for directly driving the base of an external NPN transistor. Figure 7 shows a configuration which can be used to provide +5 V with boosted current drive. A 1 Ω current sensing resistor limits the current at 0.5 A.

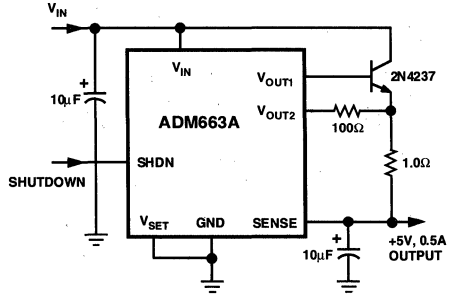

Figure 7. ADM663A Boosted Output Current (0.5 A)

Temperature Proportional Output

The ADM663A contains a V_{TC} output with a positive temperature coefficient of +2.5 mV/°C. This may be connected to the summing junction of the error amplifier (V_{SET}) through a resistor resulting in a negative temperature coefficient at the output of the regulator. This is especially useful in multiplexed LCD displays to compensate for the inherent negative temperature coefficient of the LCD threshold. At +25°C the voltage at the VTC output is typically 0.9 V. The equations for setting both the output voltage and the tempco are given below. If this function is not being used, then V_{TC} should be left unconnected.

$$V_{OUT} = V_{SET}\left(1+\frac{R2}{R1}\right)+\frac{R2}{R3}\left(V_{SET}-V_{TC}\right)$$

$$TCV_{OUT} = \frac{-R2}{R3}\left(TCV_{TC}\right)$$

where V_{SET} = +1.3 V, V_{TC} = +0.9 V, TCV_{TC} = +2.5 mV/°C

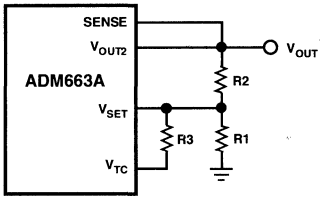

Figure 8. ADM663A Temperature Proportional Output

APPLICATION HINTS

Input-Output (Dropout Voltage)

A regulator's minimum input-output differential or dropout voltage determines the lowest input voltage for a particular output voltage. The ADM663A/ADM666A dropout voltage is 1 V at its rated output current. For example when used as a fixed +5 V regulator, the minimum input voltage is +6 V. At lower output currents (I_{OUT} < 10 mA) on the ADM663A, V_{OUT1} may be used as the output driver in order to achieve lower dropout voltages. In this case the dropout voltage depends on the voltage drop across the internal FET transistor. This may be calculated by multiplying the FET's saturation resistance by the output current, for example with V_{IN} = 9 V, R_{SAT} = 20 Ω. Therefore, the dropout voltage for 5 mA is 100 mV. As the current limit circuitry is referenced to V_{OUT2}, V_{OUT2} should be connected to V_{OUT1}. For high current operation V_{OUT2} should be used alone and V_{OUT1} left unconnected.

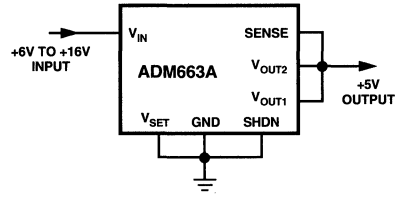

Figure 9. Low Current, Low Dropout Configuration

Thermal Considerations

The ADM663A/ADM666A can supply up to 100 mA load current and can operate with input voltages up to 16.5 V, but the package power dissipation and hence the die temperature must be kept within the maximum limits. The package power dissipation is calculated from the product of the voltage differential across the regulator times the current being supplied to the load. The power dissipation must be kept within the maximum limits given in the Absolute Maximum Ratings section.

$$P_D = (V_{IN}-V_{OUT})(I_L)$$

The die temperature is dependent on both the ambient temperature and on the power being dissipated by the device. The ADM663A/ADM666A contains an internal thermal limiting circuit which will shut down the regulator if the internal die temperature exceeds 125°C. Therefore, care must be taken to ensure that, under normal operating conditions, the die temperature is kept below the thermal limit.

$$T_J = T_A + P_D\,(\theta_{JA})$$

This may be expressed in terms of power dissipation as follows:

$$P_D = (T_J - T_A)/(\theta_{JA})$$

where:

T_J = Die Junction Temperature (°C)

T_A = Ambient Temperature (°C)

P_D = Power Dissipation (W)

θ_{JA} = Junction to Ambient Thermal Resistance (°C/W)

If the device is being operated at the maximum permitted ambient temperature of 85°C the maximum power dissipation permitted is:

$$P_D\,(max) = (T_J\,(max) - T_A)/(\theta_{JA})$$

$$P_D\,(max) = (125 - 85)/(\theta_{JA})$$

$$= 40/\theta_{JA}$$

θ_{JA} = 120°C/W for the 8-pin DIP (N-8) package

θ_{JA} = 170°C/W for the 8-pin SOIC (R-8) package

Therefore, for a maximum ambient temperature of 85°C

$$P_D\,(max) = 333\ mW\ for\ N\text{-}8$$

$$P_D\,(max) = 235\ mW\ for\ R\text{-}8$$

At lower ambient temperatures the maximum permitted power dissipation increases accordingly up to the maximum limits specified in the absolute maximum specifications.

The thermal impedance (θ_{JA}) figures given are measured in still air conditions and are reduced considerably where fan assisted cooling is employed. Other techniques for reducing the thermal impedance include large contact pads on the printed circuit board and wide traces. The copper will act as a heat exchanger thereby reducing the effective thermal impedance.

Bypass Capacitors

The high frequency performance of the ADM663A/ADM666A may be improved by decoupling the ouput using a filter capacitor. A capacitor of 0.1 µF is suitable.

An input capacitor helps reduce noise, improves dynamic performance and reduces the input dV/dt at the regulator input. A suitable input capacitor is 0.1 µF or greater.

GENERAL DESCRIPTION

The REF-01 precision voltage reference provides a stable +10V output which can be adjusted over a ±3% range with minimal effect on temperature stability. Single-supply operation over an input voltage range of 12V to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise, and low power make the REF-01 an excellent choice whenever a stable voltage reference is required. Applications include D/A and A/D converters, portable instrumentation, and digital voltmeters. Full military temperature range devices with screening to MIL-STD-883 are available. For guaranteed long-term drift see the REF-10 data sheet.

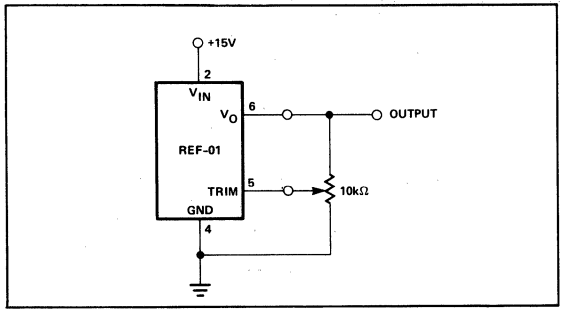
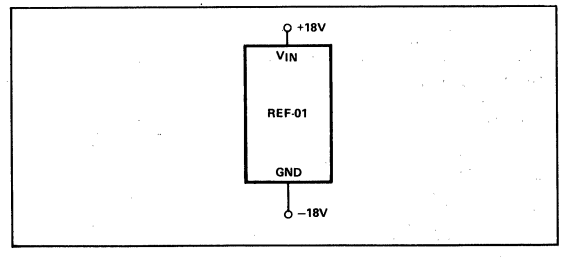
OUTPUT ADJUSTMENT



The REF-01 trim terminal can be used to adjust the output voltage over a 10V ±300mV range. This feature allows the system designer to trim system errors by setting the reference to a voltage other than 10V. Of course, the output can also be set to exactly 10.000V, or to 10.240V for binary applications.

Adjustment of the output does not significantly affect the temperature performance of the device. The temperature coefficient change is approximately 0.7 ppm/° C for 100mV of output adjustment.

BURN-IN CIRCUIT



+5V Precision Voltage Reference/Temperature Transducer

REF02

FEATURES

- 5 Volt Output ..... ±0.3% Max
- Temperature Voltage Output ..... 2.1mV/°C
- Adjustment Range ..... ±3% Min
- Excellent Temperature Stability ..... 8.5ppm/°C Max
- Low Noise ..... $15\mu V_{p-p}$ Max
- Low Supply Current ..... 1.4mA Max
- Wide Input Voltage Range ..... 7V to 40V
- High Load-Driving Capability 20mA
- No External Components
- Short-Circuit Proof
- MIL-STD-883 Screening Available
- Available in Die Form

GENERAL DESCRIPTION

The REF-02 precision voltage reference provides a stable +5V output which can be adjusted over a ±6% range with minimal effect on temperature stability. Single-supply operation over an input voltage range of 7V to 40V, low current drain of 1mA, and excellent temperature stability are achieved with an improved bandgap design. Low cost, low noise, and low power make the REF-02 an excellent choice whenever a stable voltage reference is required. Applications include D/A and A/D converters, portable instrumentation, and digital voltmeters. The versatility of the REF-02 is enhanced by its use as a monolithic temperature transducer. For +10V references, see the REF-01 and REF-10 data sheets.

NOTES:

1. Guaranteed by design.
2. Line and Load Regulation specifications include the effect of self heating.
3. Limit current in or out of pin 3 to 50nA and capacitance on pin 3 to 30pF.
4. ΔV_{OT} is defined as the absolute difference between the maximum output voltage and the minimum output voltage over the specified temperature range expressed as a percentage of 5V.

$$\Delta V_{OT} = \left| \frac{V_{MAX} - V_{MIN}}{5V} \right| \times 100$$

5. ΔV_{OT} specification applies trimmed to +5.000V or untrimmed.
6. TCV_O is defined as ΔV_{OT} divided by the temperature range, i.e.,

$$TCV_O = \frac{\Delta V_{OT}}{70°C}$$

7. Sample Tested.
8. During sink current test the device meets the output voltage specified.

+2.5V Low Power Precision Voltage Reference

REF43

FEATURES

- +2.5 Volt Output ..... ±0.05% Max
- Low Temperature Coefficient ..... 10ppm/°C Max
- Excellent Regulation
  - Load Regulation ..... 20ppm/mA Max
  - Line Regulation ..... 2ppm/V Max
- Supply Current ..... 450μA Max
- Temperature Voltage Output ..... +1.9mV/°C
- Operating Voltage Range ..... +4.5V to +40V
- Extended Industrial Temp Range ..... −40°C to +85°C
- Available in Die Form

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

GENERAL DESCRIPTION

The REF-43 is a low-power precision reference providing a stable +2.5V output independent of variations in supply voltage, load conditions or ambient temperature. It is suitable as a reference level for 8, 10 and 12-bit data acquisition systems, or wherever a stable, known voltage is required.

Tight output tolerances and low thermal drift are assured by zener-zap trimming of both output voltage and its temperature coefficient. A unique curvature correction circuit reduces the thermal curvature which is characteristic of many previous bandgap references.

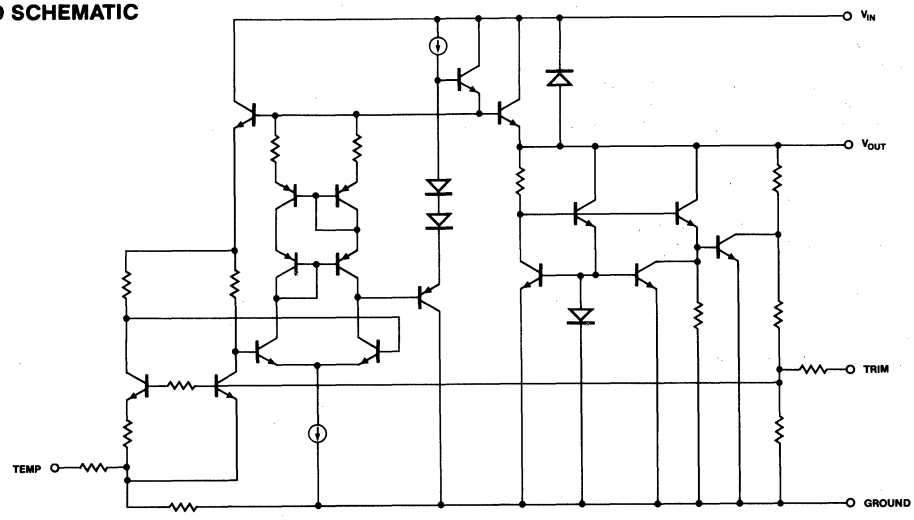
SIMPLIFIED SCHEMATIC



This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

The REF-43 may be operated with supply voltages from +4.5V to +40V. The output voltage changes by less than 178μV from one extreme of supply voltage to the other. With only 450μA maximum quiescent current, the REF-43 is ideally suited to applications where power dissipation must be minimized, as in precision battery-powered equipment. The low supply current minimizes drift due to self-heating after power-up.

A temperature output provides a means of determining system ambient temperature. Applications of the REF-43 include A/D and D/A conversion, 4-20mA transmitter/receiver operation, log amplifiers, and power-supply regulators.

For a low-cost 2.5V reference available in small-outline packages consult the REF-03 data sheet.

ABSOLUTE MAXIMUM RATINGS (Note 1)

Supply Voltage 40V
Output Short-Circuit Duration ..... Indefinite

Operating Temperature Range
REF-43B (J, Z) ..... −55°C to +125°C
REF-43F (J, Z) ..... −40°C to +85°C
REF-43G (J, Z, P, S) ..... −40°C to +85°C
Storage Temperature Range ..... −65°C to +175°C
Junction Temperature Range ..... −65°C to +175°C
Lead Temperature (Soldering, 10 sec) ..... 300°C

PACKAGE TYPE	Θ_{JA} (Note 2)	Θ_{JC}	UNITS

Temperature Voltage Output Tempco	TCV_{TEMP}		–	1.9	–	–	1.9	–	–	1.9	–	mV/°C

NOTES:
1. Output voltage temperature coefficient is measured by the box method. The tempco is defined as the slope of the diagonal of a box drawn around the output voltage plotted against temperature. V_{OUT} is measured at T_{MIN}, 25°C and T_{MAX} for the applicable temperature range. The lowest of these three readings is subtracted from the highest reading and the resulting difference is divided by (T_{MAX} - T_{MIN}).
2. Guaranteed by Load Regulation test.

GENERAL DESCRIPTION

REF19x series precision bandgap voltage references utilize a patented temperature drift curvature correction circuit and laser trimming of highly stable thin-film resistors to achieve a very low temperature coefficient and a high initial accuracy.

The REF19x series are micropower, Low Dropout Voltage (LDV) devices providing a stable output voltage from supplies as low as 100 mV above the output voltage and consuming less than 45 µA of supply current. In shutdown mode, which is enabled by applying a low TTL or CMOS level to the shutdown pin, the output is turned off and supply current is further reduced to less than 15 µA.

The REF19x series references are specified over the extended industrial temperature range (–40°C to +85°C) and High Operating Temperature (HOT) range (–40°C to +125°C) for applications such as automotive.

All grades are available in 8-pin SOIC and PDIP. Products are also available in die form. TSSOP 8-pin available Q4, 1994.

Table I.

LOAD REGULATION	$\Delta V_O/\Delta I_{LOAD}$	1 mA < I_{LOAD} < 30 mA, V_{IN} = V_O +1.3 V		mV/mA
DROPOUT VOLTAGE	V_O–V+	I_{LOAD} = 10 mA	0.5	V
		I_{LOAD} = 30 mA	1.3	V
STANDBY MODE INPUT				
Logic Input High	V_{IH}		2.4	V
Logic Input Low	V_{IL}		0.8	V
SUPPLY CURRENT		No Load	45	µA
Standby Mode			15	µA

NOTE
For proper operation, a 1 µF capacitor is required between the output pins and the GND pin of the REF19x. Electrical tests and wafer probe to the limits shown. Due to variations in assembly methods and normal yield loss, yield after packaging is not guaranteed for standard product dice. Consult factory to negotiate specifications based on dice lot qualifications through sample lot assembly and testing.

ABSOLUTE MAXIMUM RATINGS[1]

Supply Voltage ..... +18 V
Output Short-Circuit Duration ..... Indefinite
Storage Temperature Range
P, S Packages ..... –65°C to +150°C
Operating Temperature Range
REF19x ..... –40°C to +85°C
Junction Temperature Range
P, S Packages ..... –65°C to +125°C
Lead Temperature Range (Soldering, 60 sec) ..... +300°C

Package Type	θ_{JA}[2]	θ_{JC}	Units
8-Pin Plastic DIP (P)	103	43	°C/W
8-Pin SOIC (S)	158	43	°C/W

NOTES
[1]Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.
[2]θ_{JA} is specified for the worst case conditions, i.e., θ_{JA} is specified for device in socket for P-DIP, and θ_{JA} is specified for device soldered in circuit board for SOIC package.

ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option*
REF19xGP	–40°C to +85°C	8-Pin Plastic DIP	N-8
REF19xGS	–40°C to +85°C	8-Pin SOIC	SO-8
REF19xGBC	+25°C	DICE	

*For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

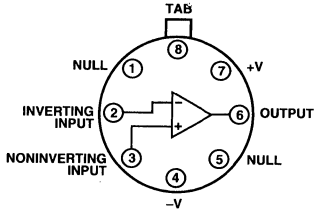
ANALOG DEVICES

High Performance, BiFET Operational Amplifiers

AD542/AD544/AD547

FEATURES
Ultralow Drift: 1 μV/°C (AD547L)
Low Offset Voltage: 0.25 mV (AD547L)
Low Input Bias Currents: 25 pA max
Low Quiescent Current: 1.5 mA
Low Noise: 2 μV p-p
High Open Loop Gain: 110 dB
High Slew Rate: 13 V/μs
Fast Settling to ±0.01%: 3 μs
Low Total Harmonic Distortion: 0.0025%
Available in Hermetic Metal Can and Die Form
MIL-STD-883B Versions Available
Dual Versions Available: AD642, AD644, AD647

CONNECTION DIAGRAM



NOTE: PIN 4 CONNECTED TO CASE

PRODUCT DESCRIPTION

The BiFET series of precision, monolithic FET-input op amps are fabricated with the most advanced BiFET and laser trimming technologies. The AD542, AD544, AD547 series offers bias currents significantly lower than currently available BiFET devices, 25 pA max, warmed up.

In addition, the offset voltage is laser trimmed to less than 0.25 mV on the AD547L, which is achieved by utilizing Analog Devices' exclusive laser wafer trimming (LWT) process. When combined with the AD547's low offset drift (1 μV/°C), these features offer the user performance superior to existing BiFET op amps at low BiFET pricing.

The AD542 or AD547 is recommended for any operational amplifier application requiring excellent dc performance at low to moderate cost. Precision instrument front ends requiring accurate amplification of millivolt level signals from megohm source impedances will benefit from the device's excellent combination of low offset voltage and drift, low bias current and low 1/f noise. High common-mode rejection (80 dB, min on the "K" and "L" grades) and high open-loop gain, even under heavy loading, ensures better than "12-bit" linearity in high impedance buffer applications.

The AD544 is recommended for any op amp applications requiring excellent ac and dc performance at low cost. The 2 MHz bandwidth and low offset of the AD544 make it the first choice as an output amplifier for current output D/A converters, such as the AD7541, 12-bit CMOS DAC.

Devices in this series are available in four grades: the "J," "K," and "L" grades are specified over the 0°C to +70°C temperature range and the "S" grade over the –55°C to +125°C operating temperature range. All devices are offered in the hermetically sealed, TO-99 metal can package.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

PRODUCT HIGHLIGHTS

1. Improved bipolar and JFET processing results in the lowest bias current available in a monolithic FET op amp.
2. Analog Devices, unlike some manufacturers, specifies each device for the maximum bias current at either input in the warmed-up condition, thus assuring the user that the device will meet its published specifications in actual use.
3. Advanced laser wafer trimming techniques reduce offset voltage drift to 1 μV/°C max and offset voltage to only 0.25 mV max on the AD547L.
4. Low voltage noise (2 μV p-p) and low offset voltage drift enhance performance as a precision op amp.
5. High slew rate (13 V/μs) and fast settling time to 0.01% (3 μs) make the AD544 ideal for D/A, A/D, sample-hold circuits and high speed integrators.
6. Low harmonic distortion (0.0025%) make the AD544 an ideal choice in audio applications.
7. Bare die are available for use in hybrid circuit applications.

NOTES
[1]Open-Loop Gain is specified with V_{OS} both nulled and unnulled.
[2]Input Offset Voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.
[3]Input Offset Voltage Drift is specified with the offset voltage unnulled. Nulling will induce an additional 3 μV/°C/mV of nulled offset.
[4]Bias Current specifications are guaranteed at either input after 5 minutes of operation at T_A = +25°C. For higher temperatures, the current doubles every 10°C.
[5]Defined as the maximum safe voltage between inputs, such that neither exceeds ±10 V from ground.
Specifications subject to change without notice.
Specifications shown in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels.
All min and max specifications are guaranteed, although only those shown in **boldface** are tested on all production units.

1 pA Monolithic Electrometer Operational Amplifier

AD546*

FEATURES

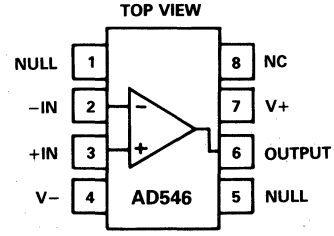
DC PERFORMANCE
- 1 mV max Input Offset Voltage
- Low Offset Drift: 20 μV/°C
- 1 pA max Input Bias Current
- Input Bias Current Guaranteed Over Full Common-Mode Voltage Range

AC PERFORMANCE
- 3 V/μs Slew Rate
- 1 MHz Unity Gain Bandwidth
- Low Input Voltage Noise: 4 μV p–p, 0.1 Hz to 10 Hz
- Available in a Low Cost, 8-Pin Plastic Mini-DIP
- Standard Op Amp Pinout

APPLICATIONS
- Electrometer Amplifiers
- Photodiode Preamps
- pH Electrode Buffers
- Log Ratio Amplifiers

CONNECTION DIAGRAM

8-Pin Plastic
Mini-DIP Package



PRODUCT DESCRIPTION

The AD546 is a monolithic electrometer combining the virtues of low (1 pA) input bias current with the cost effectiveness of a plastic mini-DIP package. Both input offset voltage and input offset voltage drift are laser trimmed, providing very high performance for such a low cost amplifier.

Input bias currents are reduced significantly by using "topgate" JFET technology. The 10^{15} Ω common-mode impedance, resulting from a bootstrapped input stage, insures that input bias current is essentially independent of common-mode voltage variations.

The AD546 is suitable for applications requiring both minimal levels of input bias current and low input offset voltage. Applications for the AD546 include use as a buffer amplifier for current output transducers such as photodiodes and pH probes. It may also be used as a precision integrator or as a low droop rate sample and hold amplifier. The AD546 is pin compatible with standard op amps; its plastic mini-DIP package is ideal for use with automatic insertion equipment.

The AD546 is available in two performance grades, all rated over the 0 to +70°C commercial temperature range, and packaged in an 8-pin plastic mini-DIP.

PRODUCT HIGHLIGHTS

1. The input bias current of the AD546 is specified, 100% tested and guaranteed with the device in the fully warmed-up condition.
2. The input offset voltage of the AD546 is laser trimmed to less than 1 mV (AD546K).
3. The AD546 is packaged in a standard, low cost, 8-pin mini-DIP.
4. A low quiescent supply current of 700 μA minimizes any thermal effects which might degrade input bias current and input offset voltage specifications.

NOTES
[1]Bias current specifications are guaranteed maximum, at either input, after 5 minutes of operation at T_A = +25°C. Bias current increases by a factor of 2.3 for every 10°C rise in temperature.
[2]Input offset voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.
[3]Defined as max continuous voltage between inputs, such that neither exceeds ±10 V from ground.
[4]For outline information see Package Information section.

Specifications subject to change without notice.

Specifications in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in **boldface** are tested on all production units.

Internal Power Dissipation . . . . . 500 mW
Input Voltage[2] . . . . . ±18 V
Output Short Circuit Duration . . . . . Indefinite
Differential Input Voltage . . . . . $+V_S$ and $-V_S$
Storage Temperature Range . . . . . −65°C to +125°C
Operating Temperature Range . . . . . 0 to +70°C
Lead Temperature Range
(Soldering 60 seconds) . . . . . 300°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]For supply voltages less than ±18 V, the absolute maximum input voltage is equal to the supply voltage.

ESD PRECAUTIONS

Charges as high as 4000 V readily accumulate on the human body and test equipment and discharge without detection. Therefore, reasonable ESD precautions are recommended to avoid functional damage or performance degradation. Unused devices should be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual.*

ANALOG DEVICES

Precision, Low Power BiFET Op Amp

AD548

FEATURES

Enhanced Replacement for LF441 and TL061
DC Performance:
200μA max Quiescent Current
10pA max Bias Current, Warmed Up (AD548C)
250μV max Offset Voltage (AD548C)
2μV/°C max Drift (AD548C)
2μV p-p Noise, 0.1 to 10Hz
AC Performance:
1.8V/μs Slew Rate
1MHz Unity Gain Bandwidth
Available in Plastic, Hermetic Cerdip and Hermetic Metal Can Packages and in Chip Form
Available in Tape and Reel in Accordance with EIA-481A Standard
MIL-STD-883B Parts Available
Dual Version Available: AD648
Surface Mount (SOIC) Package Available

PRODUCT DESCRIPTION

The AD548 is a low power, precision monolithic operational amplifier. It offers both low bias current (10pA max, warmed up) and low quiescent current (200μA max) and is fabricated with ion-implanted FET and laser wafer trimming technologies. Input bias current is guaranteed over the AD548's entire common-mode voltage range.

The economical J grade has a maximum guaranteed input offset voltage of less than 2mV and an input offset voltage drift of less than 20μV/°C. The C grade reduces input offset voltage to less than 0.25mV and offset voltage drift to less than 2μV/°C. This level of dc precision is achieved utilizing Analog's laser wafer drift trimming process. The combination of low quiescent current and low offset voltage drift minimizes changes in input offset voltage due to self-heating effects. Four additional grades are offered over the commercial, industrial and military temperature ranges.

The AD548 is recommended for any dual supply op amp application requiring low power and excellent dc and ac performance. In applications such as battery-powered, precision instrument front ends and CMOS DAC buffers, the AD548's excellent combination of low input offset voltage and drift, low bias current and low 1/f noise reduces output errors. High common-mode rejection (86dB, min on the "C" grade) and high open-loop gain ensures better than 12-bit linearity in high impedance, buffer applications.

The AD548 is pinned out in a standard op amp configuration and is available in six performance grades. The AD548J and AD548K are rated over the commercial temperature range of 0 to +70°C. The AD548A, AD548B and AD548C are rated over the industrial temperature range of −40°C to +85°C. The AD548S is rated over the military temperature range of −55°C to +125°C and is available processed to MIL-STD-883B, Rev. C.

The AD548 is available in an 8-pin plastic mini-DIP, cerdip, TO-99 metal can, surface mount (SOIC), or in chip form.

PRODUCT HIGHLIGHTS

1. A combination of low supply current, excellent dc and ac performance and low drift makes the AD548 the ideal op amp for high-performance, low-power applications.
2. The AD548 is pin compatible with industry standard op amps such as the LF441, TL061, and AD542, enabling designers to improve performance while achieving a reduction in power dissipation of up to 85%.
3. Guaranteed low input offset voltage (2mV max) and drift (20μV/°C max) for the AD548J are achieved utilizing Analog Devices' laser drift trimming technology, eliminating the need for external trimming.
4. Analog Devices specifies each device in the warmed-up condition, insuring that the device will meet its published specifications in actual use.
5. A dual version, the AD648 is also available.
6. Enhanced replacement for LF441 and TL061.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 volts, which readily accumulate on the human body and on test equipment, can discharge without detection. Although devices feature proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper precautions are recommended to avoid any performance degradation or loss of functionality.

Ultralow Input Bias Current Operational Amplifier

AD549*

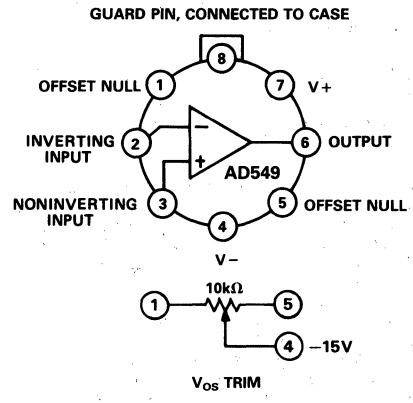
FEATURES

Ultralow Bias Current: 60 fA max (AD549L)
250 fA max (AD549J)
Input Bias Current Guaranteed Over Common-Mode Voltage Range
Low Offset Voltage: 0.25 mV max (AD549K)
1.00 mV max (AD549J)
Low Offset Drift: 5 μV/°C max (AD549K)
20 μV/°C max (AD549J)
Low Power: 700 μA max Supply Current
Low Input Voltage Noise: 4 μV p–p 0.1 to 10 Hz
MIL-STD-883B Parts Available

APPLICATIONS

Electrometer Amplifiers
Photodiode Preamp
pH Electrode Buffer
Vacuum Ion Gage Measurement

CONNECTION DIAGRAM



PRODUCT DESCRIPTION

The AD549 is a monolithic electrometer operational amplifier with very low input bias current. Input offset voltage and input offset voltage drift are laser trimmed for precision performance. The AD549's ultralow input current is achieved with "Topgate" JFET technology, a process development exclusive to Analog Devices. This technology allows the fabrication of extremely low input current JFETs compatible with a standard junction-isolated bipolar process. The 10^{15} Ω common-mode impedance, a result of the bootstrapped input stage, insures that the input current is essentially independent of common-mode voltage.

The AD549 is suited for applications requiring very low input current and low input offset voltage. It excels as a preamp for a wide variety of current output transducers such as photodiodes, photomultiplier tubes, or oxygen sensors. The AD549 can also be used as a precision integrator or low droop sample and hold. The AD549 is pin compatible with standard FET and electrometer op amps, allowing designers to upgrade the performance of present systems at little additional cost.

The AD549 is available in a TO-99 hermetic package. The case is connected to Pin 8 so that the metal case can be independently connected to a point at the same potential as the input terminals, minimizing stray leakage to the case.

The AD549 is available in four performance grades. The J, K, and L versions are rated over the commercial temperature range 0 to +70°C. The S grade is specified over the military temperature range of −55°C to +125°C and is available processed to MIL-STD-883B, Rev C. Extended reliability PLUS screening is also available. PLUS screening includes 168-hour burn-in, as well as other environmental and physical tests derived from MIL-STD-883B, Rev C.

PRODUCT HIGHLIGHTS

1. The AD549's input currents are specified, 100% tested and guaranteed after the device is warmed up. Input current is guaranteed over the entire common-mode input voltage range.
2. The AD549's input offset voltage and drift are laser trimmed to 0.25 mV and 5 μV/°C (AD549K), 1 mV and 20 μV/°C (AD549J).
3. A maximum quiescent supply current of 700 μA minimizes heating effects on input current and offset voltage.
4. AC specifications include 1 MHz unity gain bandwidth and 3 V/μs slew rate. Settling time for a 10 V input step is 5 μs to 0.01%.
5. The AD549 is an improved replacement for the AD515, OPA104, and 3528.

NOTES
[1]Bias current specifications are guaranteed after 5 minutes of operation at T_A = +25°C. Bias current increases by a factor of 2.3 for every 10°C rise in temperature.
[2]Input offset voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.
[3]Defined as max continuous voltage between the inputs such that neither input exceeds ±10 V from ground.
[4]For outline information see Package Information section.

Specifications subject to change without notice.

All min and max specifications are guaranteed. Specifications in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]For supply voltages less than ±18 V, the absolute maximum input voltage is equal to the supply voltage.

METALIZATION PHOTOGRAPH

Dimensions shown in inches and (mm).

CAUTION:

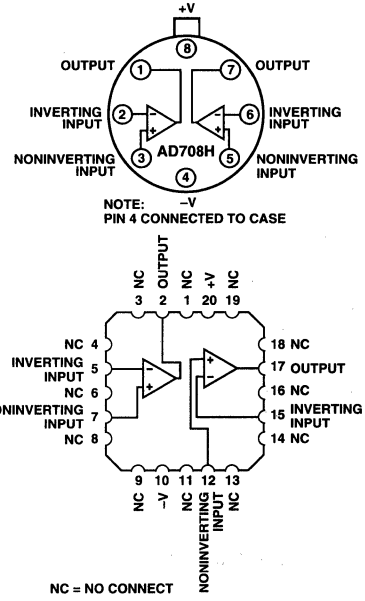
ESD (electrostatic discharge) sensitive device. Charges as high as 4000 V readily accumulate on the human body and test equipment and discharge without detection. Therefore, reasonable ESD precautions are recommended to avoid functional damage or performance degradation. Unused devices should be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual*.

Dual, Low Cost, Precision BiFET Operational Amplifiers

AD642/AD644/AD647

FEATURES
Matched Offset Voltage
Matched Offset Voltage over Temperature
Matched Bias Current
Crosstalk: –124 dB @ 1 kHz
Low Bias Current: 35 pA max (Warmed Up)
Low Offset Voltage: 250 μV max (AD647L)
Low Input Voltage Noise: 2.0 μV p-p
High Slew Rate: 13 V/μs (AD644)
Low Quiescent Current
Low Total Harmonic Distortion (0.0015%–AD644)
Standard Dual Amplifier Pin-out
MIL-STD-883B Versions Available
Single Versions Offered: AD542, AD544, AD547

CONNECTION DIAGRAMS



PRODUCT DESCRIPTION

The AD642/AD644/AD647 series of precision, monolithic FET-input op amps are pairs of matched, high speed, BiFET op amps fabricated with the most advanced BiFET and laser trimming technologies. The AD642, AD644, AD647 series offers matched bias currents significantly lower than currently available dual, BiFET devices, 35 pA max., warmed up. In addition, the offset voltage is laser trimmed to less than 0.25 mV on the AD647L, using Analog Devices' laser wafer trimming (LWT) process.

This product series achieves tight matching and temperature tracking between the amplifiers by using the most advanced ion-implantation and laser wafer drift trimming technologies. Ion-implantation permits the fabrication of precision, matched JFETs on a monolithic bipolar chip. This process optimizes the ability to produce matched amplifiers which have lower initial bias currents than other popular BiFET amplifiers. Laser wafer trimming each amplifier's input offset voltage ensures tight initial match, and combined with superior wafer processing guarantees offset tracking over the temperature range.

The AD642, AD644 and AD647 are recommended for applications requiring excellent ac and dc performance. The matched amplifiers provide a low cost solution for true instrumentation amplifiers, low drift active filters, log ratio amplifiers, and output amplifiers for four quadrant multiplying D/A converters, such as the AD7541, 12-bit CMOS DAC.

Devices in this series are available in four grades: the "J," "K," and "L" grades are specified over the 0°C to +70°C temperature range and the "S" grade over the –55°C to +125°C operating temperature range. All devices are offered in the hermetically sealed, TO-99 metal can package. In addition, the AD647 is also offered in a 20-pin, hermetic, surface mount LCC package.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

PRODUCT HIGHLIGHTS

1. Tight matching specifications ensure high performance and eliminate the need to match individual devices.
2. Analog Devices, unlike some manufacturers, specifies each device for the maximum bias current at either input in the warmed-up condition, thus assuring the user that the device will meet its published specifications in actual use.
3. Advanced laser wafer trimming techniques reduce offset voltage to only 0.25 mV max and matched side to side to 0.25 mV (AD647L), thus eliminating the need for external nulling.
4. Low voltage noise (2 μV p-p) and high open-loop gain enhance performance as a precision op amp.
5. High slew rate (13 V/μs) and fast settling time to 0.01% (3.0 μs) make the AD644 ideal for D/A, A/D, sample-hold circuits and high speed integrators.
6. Low harmonic distortion (0.0015%) and low crosstalk (–124 dB) make the AD644 an ideal choice in stereo audio applications
7. Bare die are available for use in hybrid circuit applications.

Low Noise, Low Drift FET Op Amp

AD645

FEATURES

Improved Replacement for Burr-Brown OPA-111 and OPA-121 Op Amp

LOW NOISE
2 μV p–p max, 0.1 Hz to 10 Hz
10 nV/√Hz max at 10 kHz
11 fA p–p Current Noise 0.1 Hz to 10 Hz

HIGH DC ACCURACY
250 μV max Offset Voltage
1 μV/°C max Drift
1.5 pA max Input Bias Current
114 dB Open-Loop Gain
Available in Plastic Mini-DIP, 8-Pin Header Packages, or Chip Form

IMPROVED DRIFT

APPLICATIONS
Low Noise Photodiode Preamps
CT Scanners
Precision I-V Converters

PRODUCT DESCRIPTION

The AD645 is a low noise, precision FET input op amp. It offers the pico amp level input currents of a FET input device coupled with offset drift and input voltage noise comparable to a high performance bipolar input amplifier.

The AD645 has been improved to offer the lowest offset drift in a FET op amp, 1 μV/°C. Offset voltage drift is measured and trimmed at wafer level for the lowest cost possible. An inherently low noise architecture and advanced manufacturing techniques result in a device with a guaranteed low input voltage noise of 2 μV p–p, 0.1 Hz to 10 Hz. This level of dc performance along with low input currents make the AD645 an excellent choice for high impedance applications where stability is of prime concern.

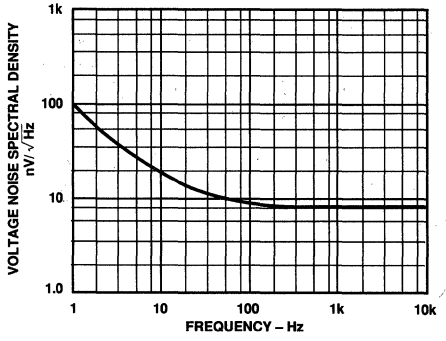

Figure 1. AD645 Voltage Noise Spectral Density vs. Frequency

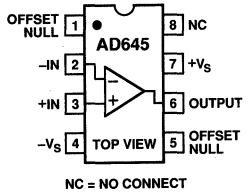
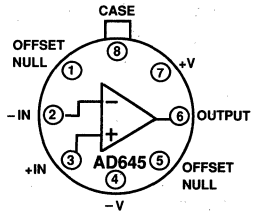
CONNECTION DIAGRAMS

8-Pin Plastic Mini-DIP (N) Package



NC = NO CONNECT

TO-99 (H) Package



NOTE: CASE IS CONNECTED TO PIN 8

The AD645 is available in six performance grades. The AD645J and AD645K are rated over the commercial temperature range of 0°C to +70°C. The AD645A, AD645B, and the ultraprecision AD645C are rated over the industrial temperature range of −40°C to 85°C. The AD645S is rated over the military temperature range of −55°C to 125°C and is available processed to MIL-STD-883B.

The AD645 is available in an 8-pin plastic mini-DIP, 8-pin header, or in die form.

PRODUCT HIGHLIGHTS

1. Guaranteed and tested low frequency noise of 2 μV p–p max and 20 nV/√Hz at 100 Hz makes the AD645C ideal for low noise applications where a FET input op amp is needed.
2. Low V_{OS} drift of 1 μV/°C max makes the AD645C an excellent choice for applications requiring ultimate stability.
3. Low input bias current and current noise (11 fA p–p 0.1 Hz to 10 Hz) allow the AD645 to be used as a high precision preamp for current output sensors such as photodiodes, or as a buffer for high source impedance voltage output sensors.

NOTES

[1]Input offset voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.

[2]Bias current specifications are guaranteed maximum at either input after 5 minutes of operation at T_A = +25°C. For higher temperature, the current doubles every 10°C.

[3]Gain = −1, R_{LOAD} = 2 kΩ.

[4]Defined as the time required for the amplifier's output to return to normal operation after removal of a 50% overload from the amplifier input.

[5]Defined as the maximum continuous voltage between the inputs such that neither input exceeds ±10 V from ground.

All min and max specifications are guaranteed.

Specifications subject to change without notice.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Thermal Characteristics:
8-Pin Plastic Mini-DIP Package: θ_{JA} = 100°C/Watt
8-Pin Header Package: θ_{JA} = 200°C/Watt

CAUTION

ESD (electrostatic discharge) sensitive device. Charges as high as 4000 V readily accumulate on the human body and test equipment and discharge without detection. Therefore, reasonable ESD precautions are recommended to avoid functional damage or performance degradation. Unused devices should be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual.*

ORDERING GUIDE

Model[1]	Temperature Range	Package Option[2]
AD645JN	0°C to +70°C	N-8
AD645KN	0°C to +70°C	N-8
AD645AH	−40°C to +85°C	H-08A
AD645BH	−40°C to +85°C	H-08A
AD645CH	−40°C to +85°C	H-08A
AD645SH/883B	−55°C to +125°C	H-08A

NOTES
[1]Chips are also available.
[2]N = Plastic mini-DIP; H = Metal Can. For outline information see Package Information section.

PRODUCT DESCRIPTION

The AD648 is a matched pair of low power, precision monolithic operational amplifiers. It offers both low bias current (10 pA max, warmed up) and low quiescent current (400 μA max) and is fabricated with ion-implanted FET and laser wafer trimming technologies. Input bias current is guaranteed over the AD648's entire common-mode voltage range.

The economical J grade has a maximum guaranteed offset voltage of less than 2 mV and an offset voltage drift of less than 20 μV/°C. The C grade reduces offset voltage to less than 0.30 mV and offset voltage drift to less than 3 μV/°C. This level of dc precision is achieved utilizing Analog's laser wafer drift trimming process. The combination of low quiescent current and low offset voltage drift minimizes changes in input offset voltage due to self-heating effects. Five additional grades are offered over the commercial, industrial and military temperature ranges.

The AD648 is recommended for any dual supply op amp application requiring low power and excellent dc and ac performance. In applications such as battery-powered, precision instrument front ends and CMOS DAC buffers, the AD648's excellent combination of low input offset voltage and drift, low bias current and low 1/f noise reduces output errors. High common-mode rejection (86 dB, min on the "C" grade) and high open-loop gain ensures better than 12-bit linearity in high impedance, buffer applications.

The AD648 is pinned out in a standard dual op amp configuration and is available in seven performance grades. The AD648J and AD648K are rated over the commercial temperature range of 0 to +70°C. The AD648A, AD648B and AD648C are rated over the industrial temperature range of −40°C to +85°C. The AD648S and AD648T are rated over the military temperature range of −55°C to +125°C and are available processed to MIL-STD-883B, Rev. C.

The AD648 is available in an 8-pin plastic mini-DIP, cerdip, SOIC, TO-99 metal can, or in chip form.

PRODUCT HIGHLIGHTS

1. A combination of low supply current, excellent dc and ac performance and low drift makes the AD648 the ideal op amp for high performance, low power applications.
2. The AD648 is pin compatible with industry standard dual op amps such as the LF442, TL062, and AD642, enabling designers to improve performance while achieving a reduction in power dissipation of up to 85%.
3. Guaranteed low input offset voltage (2 mV max) and drift (20 μV/°C max) for the AD648J are achieved utilizing Analog Devices' laser drift trimming technology.
4. Analog Devices specifies each device in the warmed-up condition, insuring that the device will meet its published specifications in actual use.
5. Matching characteristics are excellent for all grades. The input offset voltage matching between amplifiers in the AD648J is within 2 mV, for the C grade matching is within 0.4 mV.
6. Crosstalk between amplifiers is less than −120 dB at 1 kHz.
7. The AD648 is available in chip form.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Input Offset Voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.
[2]Bias Current specifications are guaranteed maximum at either input after 5 minutes of operation at T_A = +25°C. For higher temperature, the current doubles every 10°C.
[3]Matching is defined as the difference between parameters of the two amplifiers.
[4]Defined as voltages between inputs, such that neither exceeds ±10 V from ground.
[5]For outline information see Package Information section.
Specifications subject to change without notice.

Picoampere Input Current, Bipolar Operational Amplifiers

AD704/AD705/AD706

FEATURES

HIGH DC PRECISION
- Low Offset Voltage
  - (75 μV max: AD704)
  - (35 μV max: AD705)
  - (50 μV max: AD706)
- Low Offset Drift
  - (1.0 μV/°C max: AD704)
  - (0.6 μV/°C max: AD705)
  - (0.6 μV/°C max: AD706)
- Low Input Bias Currents
  - (150 pA max: AD704)
  - (100 pA max: AD705)
  - (110 pA max: AD706)

LOW NOISE
- 0.5 μV p-p typ Voltage Noise (0.1 Hz to 10 Hz)

LOW POWER
- 600 μA max Supply Current per Amplifier

AC PERFORMANCE
- 0.15 V/μs Slew Rate
- 800 kHz Unity Gain Crossover Frequency
- 10,000 pF Capacitive Load Drive Capability

LOW COST

MIL-STD-883B Versions Available (Single or Quad)

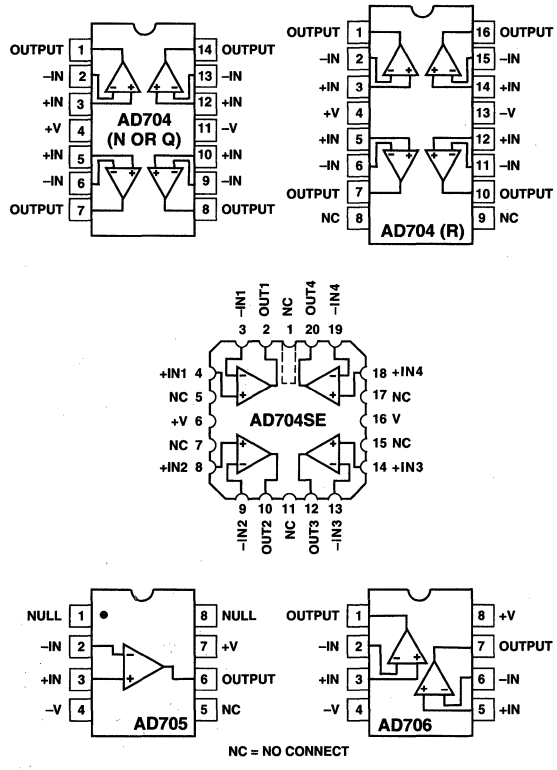
Single: AD705

Dual: AD706

Quad: AD704

APPLICATIONS
- Industrial/Process Controls
- Weigh Scales
- Medical Instrumentation (ECG/EKG)
- Low Frequency Active Filters
- Precision Integrators

FUNCTIONAL BLOCK DIAGRAMS



PRODUCT DESCRIPTION

The AD704/AD705/AD706 series are low power, bipolar op amps that have the low input bias current of BiFET amplifiers, but offer a significantly lower I_B drift over temperature. This series offers many of the advantages of BiFET and bipolar op amps without their inherent disadvantages. They utilize superbeta bipolar input transistors to achieve the picoampere input bias current levels of FET input amplifiers (at room temperature), while their I_B typically increases 5 times vs. BiFET amplifiers which exhibit a 1000× increase over temperature. Superbeta bipolar technology also permits these amplifiers to achieve the microvolt offset voltages and low noise characteristics of a precision bipolar input amplifier.

Since these amplifiers have only 1/20 of the input bias current of an industry standard OP07, the AD704/AD705/AD706 do not require the commonly used "balancing" resistor. Furthermore, the current noise is 1/5 that of the OP07, which makes these amplifiers usable with much higher source impedances. At 1/6 the supply current (per amplifier) of the OP07, these amplifiers are better suited for today's higher density systems and battery powered applications.

The AD704, AD705 and AD706 are excellent choices for use in low frequency active filters for 12- and 14-bit data acquisition systems, in precision instrumentation, and as high quality integrators. These amplifiers are internally compensated for unity gain and are available in various performance grades. The "J" and "K" grades are rated over the commercial temperature range of 0°C to +70°C. The "A" and "B" grades are rated over the industrial temperature range of –40°C to +85°C. The "T" grade is rated over the military temperature range of –55°C to +125°C. Select versions are available processed to MIL-STD-883B, Rev. C.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Bias current specifications are guaranteed maximum at either input.
[2]Input bias current match is the maximum difference between corresponding inputs of all amplifiers on the chip.
[3]CMRR match is the difference of $\Delta V_{OS}/\Delta V_{CM}$ between any two amplifiers.
[4]PSRR match is the difference between $\Delta V_{OS}/\Delta V$ SUPPLY for any two amplifiers.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

Supply Voltage ..... ±18 V
Internal Power Dissipation[2] ..... 650 mW
Input Voltage ..... $\pm V_S$
Differential Input Voltage[3] ..... ±0.7 V
Output Short Circuit Duration ..... Indefinite
Storage Temperature Range (N, R) ..... –65°C to +125°C
Storage Temperature Range (Q, H) ..... –65°C to +150°C
Operating Temperature Range
AD70xJ/K ..... 0°C to +70°C
AD70xA/B ..... –40°C to +85°C
AD70xS/T ..... –55°C to +125°C
Lead Temperature Range (Soldering 60 sec) ..... +300°C

NOTES

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]Specification is for device in free air:

8-Pin Plastic Package: θ_{JA} = 165°C/Watt
8-Pin Cerdip Package: θ_{JA} = 110°C/Watt
8-Pin Small Outline Package: θ_{JA} = 155°C/Watt
14-Pin Plastic Package: θ_{JA} = 150°C/Watt
14-Pin Cerdip Package: θ_{JA} = 110°C/Watt
16-Pin SOIC Package: θ_{JA} = 100°C/Watt
20-Terminal LCC Package: θ_{JA} = 150°C/Watt

[3]The input pins of these amplifiers are protected by back-to-back diodes. If the differential voltage exceeds ±0.7 V, external series protection resistors should be added to limit the input current to less than 25 mA.

*For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although these devices feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

Ultralow Offset and Drift Operational Amplifiers

AD707/AD708

FEATURES

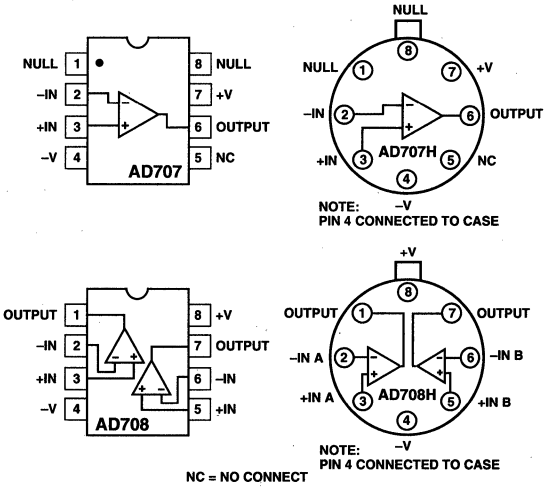
Very High DC Precision
- **Low Offset Voltages**
  - **(15 μV max: AD707)**
  - **(30 μV max: AD708)**
- **Low Offset Drift**
  - **(0.1 μV/°C max: AD707)**
  - **(0.3 μV/°C max: AD708)**
- **Low Input Bias Current: 1 nA max**

Low Noise: 0.35 μV p-p max (0.1 Hz to 10 Hz)
130 dB min CMRR
120 dB min PSRR
AC Performance
- **0.3 V/μs Slew Rate**
- **900 kHz Closed-Loop Bandwidth**

Matching Characteristics
- **30 μV max Offset Voltage Match**
- **0.3 μV/°C max Offset Drift Match**
- **130 dB min CMRR Match**

MIL-STD-883B Versions Available
Single: AD707
Dual: AD708

FUNCTIONAL BLOCK DIAGRAMS



PRODUCT DESCRIPTION

The AD707 (single) and AD708 (dual) are very high precision, monolithic operational amplifiers. Each device offers excellent dc precision with the best available max offset voltage and max offset voltage drift of any single/dual bipolar combination available.

The AD707 and AD708 set new standards for precision op amps by providing 5 V/μV min open-loop gain and guaranteed max input voltage noise of 350 nV p-p (0.1 Hz to 10 Hz). All dc specifications show excellent stability over temperature, with offset voltage drift typically 0.1 μV/°C and input bias current drift of 25 pA/°C max. Both CMRR (130 dB max) and PSRR (120 dB max) are an order of magnitude improved over any available monolithic op amp.

The AD707 and AD708 are available in seven performance grades. The "J" and "K" grades are rated over the commercial temperature range of 0°C to +70°C. The "A," "B" and "C" grades are rated over the industrial temperature range of –40°C to +85°C. The "S" and "T" grades are rated over the military temperature range of –55°C to +125°C. Select versions are also available processed to MIL-STD-883B, Rev. C.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

PRODUCT HIGHLIGHTS

1. The combination of outstanding matching and individual specifications make the AD707 and AD708 ideal for constructing high gain, precision instrumentation amplifiers.
2. The low offset voltage drift and low noise of the AD707 and AD708 allow the user to amplify very small signals without sacrificing overall system performance.
3. The AD707 and AD708 can be used where chopper amplifiers are required, but without the inherent noise and application problems.
4. The AD707 is an improved, pin-for-pin replacement for the LT1001, and the AD708 is an improved, pin-for-pin replacement for the LT1002.

SPECIFICATIONS (V_{DD} = ±15 V @ T_A = +25°C unless otherwise noted)

NOTES
[1]Input offset voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.
[2]Matching is defined as the difference between parameters of the two amplifiers.

All min and max specifications are guaranteed. Specifications in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels.
Specifications subject to change without notice.

*For outline information see Package Information section.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD707 and AD708 feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

Precision, Low Cost, High Speed, BiFET Op Amps

AD711/AD712/AD713

FEATURES
Enhanced Replacements for
TL081; TL082; TL084
LF411; LF412; LF347

AC PERFORMANCE
Settles to ±0.01% in 1.0 µs
16 V/µs min Slew Rate
3 MHz min Unity Gain Bandwidth
0.0003% Total Harmonic Distortion (THD)

DC PERFORMANCE
Low Offset Voltages
(0.25 mV max—AD711C)
(0.30 mV max—AD712C)
(0.50 mV max—AD713K)
Low Offset Drift
(3 µV/°C max—AD711C)
(5 µV/°C max—AD712C)
200 V/mV min Open-Loop Gain
Low Noise (0.1 Hz to 10 Hz)
(4 µV p-p max—AD711C)
(4 µV p-p max—AD712C)
MIL-STD-883B Versions Available
Single: AD711
Dual: AD712
Quad: AD713

APPLICATIONS
Active Filters
Output Buffers for 12- and 14-Bit DACs
Input Buffers for Precision ADCs
Photo Diode Preamplifier Applications

PRODUCT DESCRIPTION

The AD711/AD712/AD713 series are high speed, precision, monolithic operational amplifiers offering high performance at very modest prices. Their very low offset voltage and offset voltage drift are results of advanced laser wafer trimming technology. These benefits allow the user to easily upgrade existing designs that use older precision BiFETs and, in many cases, bipolar op amps.

The superior ac and dc performance of these op amps make them suitable for active filter designs. With a slew rate of 16 V/µs and settling times of 1 µs to 0.01%, the AD711/AD712/AD713 series is ideal for use as buffers for 12-bit D/A and A/D converters and as high speed integrators. The settling time is unmatched by any similar IC amplifier. The combination of excellent noise performance and low input current also make these amplifiers useful for photo diode preamplifiers. Common-mode rejection of 88 dB and open loop gain of 400 V/mV insure 12-bit performance even in high speed, unity gain, buffer circuits. These amplifiers are pinned out in standard op amp configurations and are available in various performance grades. The "J" and "K" grades are rated over the commercial temperature range of 0°C to +70°C. The "A," "B," and "C" grades are rated over the industrial temperature range of –40°C to +85°C. The "S" and "T" grades are rated over the military temperature range of –55°C to +125°C. Select versions are available processed to MIL-STD-883B, Rev. C or Standard Military Drawings.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

PRODUCT HIGHLIGHTS

1. The AD711/AD712/AD713 series offers excellent overall performance at competitive prices.
2. Analog Devices' advanced processing technology and 100% testing guarantees a low input offset voltage (0.25 mV max AD711C; 0.30 mV max AD712C). Input offset voltages are specified in the warmed up condition. Analog Devices' laser wafer drift trimming process reduces input offset voltage drifts to 3 µV/°C (AD711C) or 5 µV/°C (AD712C).
3. Along with precision dc performance, the AD711, AD712 and AD713 offer excellent dynamic response. They settle to ±0.01% in 1 µs and have a 100% tested minimum slew rate of 16 V/µs. This makes these parts ideal for DAC and ADC buffers, which require a combination of superior ac and dc performance.
4. Analog Devices' well matched, ion-implanted JFETs ensure low input bias currents and low input offset currents. Both input bias and offset currents are guaranteed in the warmed-up condition.

AD711/AD712/AD713–SPECIFICATIONS

NOTES

[1]Input Offset Voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.

[2]Bias Current specifications are guaranteed maximum at either input after 5 minutes of operation at T_A = +25°C. For higher temperatures, the current doubles every 10°C.

[3]Defined as voltage between inputs, such that neither exceeds ±10 V from ground.

[4]Typically exceeding –14.1 V negative common-mode voltage on either input results in an output phase reversal.

Specifications subject to change without notice.

Ultralow Noise BiFET Op Amp

AD743

FEATURES

ULTRALOW NOISE PERFORMANCE
- 2.9 nV/$\sqrt{Hz}$ at 10 kHz
- 0.38 μV p–p, 0.1 to 10 Hz
- 6.9 fA/$\sqrt{Hz}$ Current Noise at 1 kHz

EXCELLENT DC PERFORMANCE
- 0.5 mV max Offset Voltage
- 250 pA max Input Bias Current
- 1000 V/mV min Open-Loop Gain

AC PERFORMANCE
- 2.8 V/μs Slew Rate
- 4.5 MHz Unity-Gain Bandwidth
- THD = 0.0003% @ 1 kHz
- Available in Tape and Reel in Accordance with EIA-481A Standard

APPLICATIONS
- Sonar Preamplifiers
- High Dynamic Range Filters (>140 dB)
- Photodiode and IR Detector Amplifiers
- Accelerometers

PRODUCT DESCRIPTION

The AD743 is an ultralow noise precision, FET input, monolithic operational amplifier. It offers a combination of the ultralow voltage noise generally associated with bipolar input op amps and the very low input current of a FET-input device. Furthermore, the AD743 does not exhibit an output phase reversal when the negative common-mode voltage limit is exceeded.

The AD743's guaranteed, maximum input voltage noise of 4.0 nV/$\sqrt{Hz}$ at 10 kHz is unsurpassed for a FET-input monolithic op amp, as is the maximum 1.0 μV p–p, 0.1 to 10 Hz noise. The AD743 also has excellent dc performance with 250 pA maximum input bias current and 0.5 mV maximum offset voltage.

The AD743 is specifically designed for use as a preamp in capacitive sensors, such as ceramic hydrophones. It is available in five performance grades. The AD743J and AD743K are rated over the commercial temperature range of 0°C to +70°C. The AD743A and AD743B are rated over the industrial temperature range of −40°C to +85°C. The AD743S is rated over the military temperature range of −55°C to +125°C and is available processed to MIL-STD-883B, Rev. C.

The AD743 is available in 8-pin plastic mini-DIP, 8-pin cerdip, 16-pin SOIC, or in chip form.

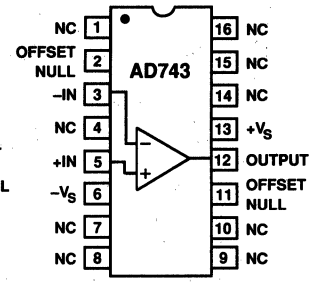
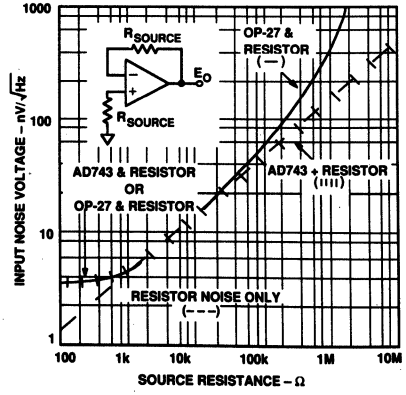
16-Pin SOIC (R) Package



PRODUCT HIGHLIGHTS

1. The low offset voltage and low input offset voltage drift of the AD743 coupled with its ultralow noise performance mean that the AD743 can be used for upgrading many applications now using bipolar amplifiers.
2. The combination of low voltage and low current noise make the AD743 ideal for charge sensitive applications such as accelerometers and hydrophones.
3. The low input offset voltage and low noise level of the AD743 provide >140 dB dynamic range.
4. The typical 10 kHz noise level of 2.9 nV/$\sqrt{Hz}$ permits a three op amp instrumentation amplifier, using three AD743s, to be built which exhibits less than 4.2 nV/$\sqrt{Hz}$ noise at 10 kHz and which has low input bias currents.



Input Noise Voltage vs. Source Resistance

NOTES
[1]Input offset voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.
[2]Test conditions: $+V_S$ = 15 V, $-V_S$ = 12 V to 18 V and $+V_S$ = 12 V to +18 V, $-V_S$ = 15 V.
[3]Bias current specifications are guaranteed maximum at either input after 5 minutes of operation at T_A = +25°C. For higher temperature, the current doubles every 10°C.
[4]Gain = −1, R_L = 2 kΩ, C_L = 10 pF.
[5]Defined as voltage between inputs, such that neither exceeds ±10 V from common.
[6]The AD743 does not exhibit an output phase reversal when the negative common-mode limit is exceeded.

All min and max specifications are guaranteed.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

Supply Voltage . . . . . ±18 V
Internal Power Dissipation[2]
Input Voltage . . . . . $\pm V_S$
Output Short Circuit Duration . . . . . Indefinite
Differential Input Voltage . . . . . $+V_S$ and $-V_S$
Storage Temperature Range (Q) . . . . . −65°C to +150°C
Storage Temperature Range (N, R) . . . . . −65°C to +125°C
Operating Temperature Range
AD743J/K . . . . . 0°C to +70°C
AD743A/B . . . . . −40°C to +85°C
AD743S . . . . . −55°C to +125°C
Lead Temperature Range (Soldering 60 seconds) . . . . . 300°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]8-pin plastic package: θ_{JA} = 100°C/Watt, θ_{JC} = 50°C/Watt
8-pin cerdip package: θ_{JA} = 110°C/Watt, θ_{JC} = 30°C/Watt
16-pin plastic SOIC package: θ_{JA} = 100°C/Watt, θ_{JC} = 30°C/Watt

ESD SUSCEPTIBILITY

An ESD classification per method 3015.6 of MIL STD 883C has been performed on the AD743. The AD743 is a class 1 device, passing at 1000 V and failing at 1500 V on null pins 1 and 5, when tested, using an IMCS 5000 automated ESD tester. Pins other than null pins fail at greater than 2500 V.

ORDERING GUIDE

Precision, 500ns Settling BiFET Op Amp

AD744

FEATURES

AC PERFORMANCE
- 500ns Settling to 0.01% for 10V Step
- 1.5μs Settling to 0.0025% for 10V Step
- 75V/μs Slew Rate
- 0.0003% Total Harmonic Distortion (THD)
- 13MHz Gain Bandwidth – Internal Compensation
- >200MHz Gain Bandwidth (G = 1000) External Decompensation
- >1000pF Capacitive Load Drive Capability with 10V/μs Slew Rate – External Compensation

DC PERFORMANCE
- 0.25mV max Offset Voltage (AD744C)
- 3μV/°C max Drift (AD744C)
- 250V/mV min Open-Loop Gain (AD744B)
- 4μV p-p max Noise, 0.1Hz to 10Hz (AD744C)
- Available in Plastic Mini-DIP, Plastic SOIC, Hermetic Cerdip, Hermetic Metal Can Packages and Chip Form
- MIL-STD-883B Processing Available
- Surface Mount (SOIC) Package Available in Tape and Reel in Accordance with EIA-481A Standard

APPLICATIONS
- Output Buffers for 12-Bit, 14-Bit and 16-Bit DACs, ADC Buffers, Cable Drivers, Wideband Preamplifiers and Active Filters

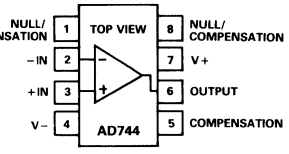
Plastic Mini-DIP (N), Small Outline (R) and Cerdip (Q) Packages



PRODUCT DESCRIPTION

The AD744 is a fast-settling, precision, FET input, monolithic operational amplifier. It offers the excellent dc characteristics of the AD711 BiFET family with enhanced settling, slew rate, and bandwidth. The AD744 also offers the option of using custom compensation to achieve exceptional capacitive load drive capability.

The single-pole response of the AD744 provides fast settling: 500ns to 0.01%. This feature, combined with its high dc precision, makes it suitable for use as a buffer amplifier for 12-bit, 14-bit or 16-bit DACs and ADCs. Furthermore, the AD744's low total harmonic distortion (THD) level of 0.0003% and gain bandwidth product of 13MHz make it an ideal amplifier for demanding audio applications. It is also an excellent choice for use in active filters in 12-bit, 14-bit and 16-bit data acquisition systems.

The AD744 is internally compensated for stable operation as a unity gain inverter or as a noninverting amplifier with a gain of two or greater. External compensation may be applied to the AD744 for stable operation as a unity gain follower. External compensation also allows the AD744 to drive 1000pF capacitive loads, slewing at 10V/μs with full stability. Alternatively, external decompensation may be used to increase the gain bandwidth of the AD744 to over 200MHz at high gains. This makes the AD744 ideal for use as ac preamps in digital signal processing (DSP) front ends.

The AD744 is available in seven performance grades. The AD744J and AD744K are rated over the commercial temperature range of 0 to +70°C. The AD744A, AD744B and AD744C are rated over the industrial temperature range of −40°C to +85°C. The AD744S and AD744T are rated over the military temperature range of −55°C to +125°C and are available processed to MIL-STD-883B, Rev. C.

Extended reliability PLUS screening is available, specified over the commercial and industrial temperature ranges. PLUS screening includes a 168-hour burn-in, as well as other environmental and physical tests.

The AD744 is available in an 8-pin plastic mini-DIP, 8-pin small outline, 8-pin cerdip or TO-99 metal can.

PRODUCT HIGHLIGHTS

1. The AD744 is a high-speed BiFET op amp that offers excellent performance at competitive prices. It outperforms the OPA602/OPA606, LF356 and LF400.
2. The AD744 offers exceptional dynamic response. It settles to 0.01% in 500ns and has a 100% tested minimum slew rate of 50V/μs (AD744B).
3. The combination of Analog Devices' advanced processing technology, laser wafer drift trimming and well-matched ion-implanted JFETs provide outstanding dc precision. Input offset voltage, input bias current, and input offset current are specified in the warmed-up condition; all are 100% tested.
4. The AD744 has a guaranteed and tested maximum voltage noise of 4μV p-p, 0.1Hz to 10Hz (AD744C).

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES

[1]Input Offset Voltage specifications are guaranteed after 5 minutes of operation at $T_A=+25°C$.

[2]PSRR test conditions: $+V_S=15V$, $-V_S=-12V$ to $-18V$ and $+V_S=12V$ to $18V$, $-V_S=-15V$.

[3]Bias Current Specifications are guaranteed maximum at either input after 5 minutes of operation at $T_A=+25°C$. For higher temperature, the current doubles every 10°C.

[4]Gain = −1, $R_L=2k$, $C_L=10pF$, refer to Figure 25.

[5]Defined as voltage between inputs, such that neither exceeds ±10V from ground.

[6]Typically exceeding −14.1V negative common-mode voltage on either input results in an output phase reversal.

[7]Open-Loop Gain is specified with V_{OS} both nulled and unnulled.

[8]Capacitive load drive specified for $C_{COMP}=20pF$ with the device connected as shown in Figure 32. Under these conditions, slew rate = 14V/μs and 0.01% settling time = 1.5μs typical. Refer to Table II for optimum compensation while driving a capacitive load.

[9]For outline information see Package Information section.

Specifications subject to change without notice.

Specifications in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

ABSOLUTE MAXIMUM RATINGS[1]

Supply Voltage	±18V
Internal Power Dissipation[2]	500mW
Input Voltage[3]	±18V
Output Short Circuit Duration	Indefinite
Differential Input Voltage	$+V_S$ and $-V_S$
Storage Temperature Range (Q, H)	−65°C to +150°C
Storage Temperature Range (N, R)	−65°C to +125°C
Operating Temperature Range	
AD744J/K	0 to +70°C
AD744A/B/C	−40°C to +85°C
AD744S/T	−55°C to +125°C
Lead Temperature Range (Soldering 60 sec)	300°C

NOTES

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indited in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]Thermal Characteristics

8-Pin Plastic Package: θ_{JC} = 33°C/W, θ_{JA} = 100°C/W
8-Pin Cerdip Package: θ_{JC} = 22°C/W, θ_{JA} = 110°C/W
8-Pin Metal Can Package: θ_{JC} = 65°C/W, θ_{JA} = 150°C/W
8-Pin SOIC Package: θ_{JC} = 42°C/W, θ_{JA} = 160°C/W

[3]For supply voltages less than ±18V, the absolute maximum input voltage is equal to the supply voltage.

Ultralow Noise, High Speed, BiFET Op Amp

AD745

FEATURES

ULTRALOW NOISE PERFORMANCE
- 2.9 nV/$\sqrt{Hz}$ at 10 kHz
- 0.38 μV p–p, 0.1 Hz to 10 Hz
- 6.9 fA/$\sqrt{Hz}$ Current Noise at 1 kHz

EXCELLENT AC PERFORMANCE
- 12.5 V/μs Slew Rate
- 20 MHz Gain Bandwidth Product
- THD = 0.0002% @ 1 kHz
- Internally Compensated for Gains of +5 (or −4) or Greater

EXCELLENT DC PERFORMANCE
- 0.5 mV max Offset Voltage
- 250 pA max Input Bias Current
- 2000 V/mV min Open Loop Gain
- Available in Tape and Reel in Accordance with EIA-481A Standard

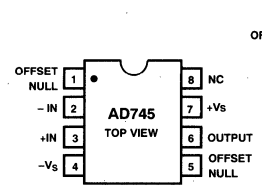
APPLICATIONS
- Sonar
- Photodiode and IR Detector Amplifiers
- Accelerometers
- Low Noise Preamplifiers
- High Performance Audio

PRODUCT DESCRIPTION

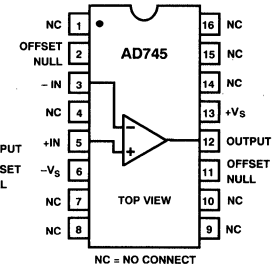
The AD745 is an ultralow noise, high speed, FET input operational amplifier. It offers both the ultralow voltage noise and high speed generally associated with bipolar input op amps and the very low input currents of FET input devices. Its 20 MHz bandwidth and 12.5 V/μs slew rate makes the AD745 an ideal amplifier for high speed applications demanding low noise and high dc precision. Furthermore, the AD745 does not exhibit an output phase reversal.

CONNECTION DIAGRAMS

8-Pin Plastic Mini-DIP (N) & 8-Pin Cerdip (Q) Packages



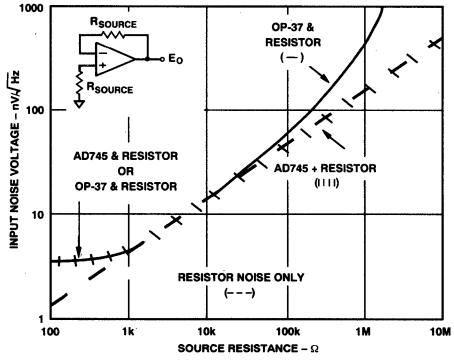
16-Pin SOIC (R) Package

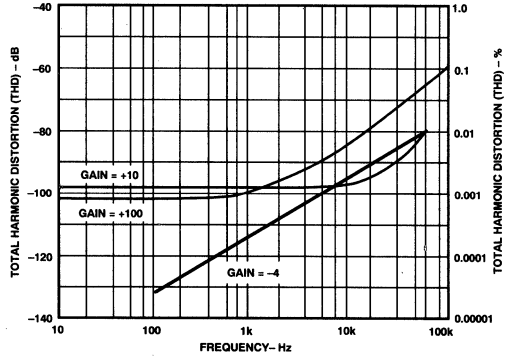


The AD745's guaranteed, tested maximum input voltage noise of 4 nV/$\sqrt{Hz}$ at 10 kHz is unsurpassed for a FET-input monolithic op amp, as is its maximum 1.0 μV p–p noise in a 0.1 to 10 Hz bandwidth. The AD745 also has excellent dc performance with 250 pA maximum input bias current and 0.5 mV maximum offset voltage.

The internal compensation of the AD745 is optimized for higher gains, providing a much higher bandwidth and a faster slew rate. This makes the AD745 especially useful as a preamplifier where low level signals require an amplifier that provides both high amplification and wide bandwidth at these higher gains. The AD745 is available in five performance grades. The AD745J and AD745K are rated over the commercial temperature range of 0°C to +70°C. The AD745A and AD745B are rated over the industrial temperature range of −40°C to +85°C. The AD745S is rated over the military temperature range of −55°C to +125°C and is available processed to MIL-STD-883B, Rev. C.

The AD745 is available in 8-pin plastic mini-DIP, 8-pin cerdip, 16-pin SOIC, or in chip form.





This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

ESD SUSCEPTIBILITY

An ESD classification per method 3015.6 of MIL STD 883C has been performed on the AD745, which is a class 1 device. Using an IMCS 5000 automated ESD tester, the two null pins will pass at voltages up to 1000 volts, while all other pins will pass at voltages exceeding 2500 volts.

Dual Precision, 500 ns Settling, BiFET Op Amp

AD746

FEATURES

AC PERFORMANCE
- 500 ns Settling to 0.01% for 10 V Step
- 75 V/μs Slew Rate
- 0.0001% Total Harmonic Distortion (THD)
- 13 MHz Gain Bandwidth
- Internal Compensation for Gains of +2 or Greater

DC PERFORMANCE
- 0.5 mV max Offset Voltage (AD746B)
- 10 μV/°C max Drift (AD746B)
- 175 V/mV min Open Loop Gain (AD746B)
- 2 μV p–p Noise, 0.1 Hz to 10 Hz
- Available in Plastic Mini-DIP, Cerdip and Surface Mount Packages
- Available in Tape and Reel in Accordance with EIA-481A Standard
- MIL-STD-883B Processing also Available
- Single Version: AD744

APPLICATIONS
- Dual Output Buffers for 12- and 14-Bit DACs
- Input Buffers for Precision ADCs, Wideband Preamplifiers and Low Distortion Audio Circuitry

PRODUCT DESCRIPTION

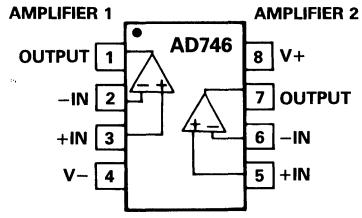
The AD746 is a dual operational amplifier, consisting of two AD744 BiFET op amps on a single chip. These precision monolithic op amps offer excellent dc characteristics plus rapid settling times, high slew rates and ample bandwidths. In addition, the AD746 provides the close matching ac and dc characteristics inherent to amplifiers sharing the same monolithic die.

The single pole response of the AD746 provides fast settling: 500 ns to 0.01%. This feature, combined with its high dc precision, makes it suitable for use as a buffer amplifier for 12- or 14-bit DACs and ADCs. Furthermore, the AD746's low total harmonic distortion (THD) level of 0.0001% and very close matching ac characteristics make it an ideal amplifier for many demanding audio applications.

The AD746 is internally compensated for stable operation as a unity gain inverter or as a noninverting amplifier with a gain of 2 or greater. It is available in four performance grades. The AD746J is rated over the commercial temperature range of 0 to +70°C. The AD746A and AD746B are rated over the industrial temperature range of −40°C to +85°C. The AD746S is rated over the military temperature range of −55°C to +125°C and is available processed to MIL-STD-883B, Rev. C.

CONNECTION DIAGRAM

Plastic Mini-DIP (N)
Cerdip (Q) and
Plastic SOIC (R) Packages



The AD746 is available in three 8-pin packages: plastic mini-DIP, hermetic cerdip and surface mount (SOIC).

PRODUCT HIGHLIGHTS

1. The AD746 offers exceptional dynamic response for high speed data acquisition systems. It settles to 0.01% in 500 ns and has a 100% tested minimum slew rate of 50 V/μs (AD746B).
2. Outstanding dc precision is provided by a combination of Analog Devices' advanced processing technology, laser wafer drift trimming and well-matched ion-implanted JFETs. Input offset voltage, input bias current and input offset current are specified in the warmed-up condition and are 100% tested.
3. Differential and multichannel systems will benefit from the AD746's very close matching of ac characteristics. Input offset voltage specs are fully tested and guaranteed to a maximum of 0.5 mV (AD746B).
4. The AD746 has very close, guaranteed matching of input bias current between its two amplifiers.
5. Unity gain stable version AD712 also available.

This is an abridged data sheet. To obtain the most recent version or complete data sheet, call our fax retrieval system at 1-800-446-6212.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]8-Pin Plastic Package: θ_{JA} = 100°C/Watt, θ_{JC} = 50°C/Watt
8-Pin Cerdip Package: θ_{JA} = 110°C/Watt, θ_{JC} = 30°C/Watt
8-Pin Small Outline Package: θ_{JA} = 160°C/Watt, θ_{JC} = 42°C/Watt

Low Power, Low Noise Precision FET Op Amp

AD795

FEATURES

Low Power Replacement for Burr-Brown OPA-111, OPA-121 Op Amps
Low Noise
- **2.5 μV p-p max, 0.1 Hz to 10 Hz**
- **11 nV/√Hz max at 10 kHz**
- **0.6 fA/√Hz at 1 kHz**

High DC Accuracy
- **250 μV max Offset Voltage**
- **3 μV/°C max Drift**
- **1 pA max Input Bias Current**
- **Low Power: 1.5 mA Max Supply Current**

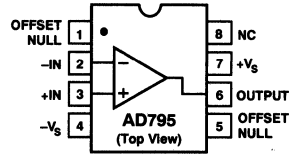
Available in Low Cost Plastic Mini-DIP and Surface Mount (SOIC) Packages

APPLICATIONS

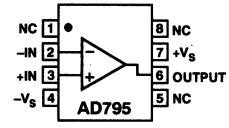
Low Noise Photodiode Preamps
CT Scanners
Precision I-to-V Converters

CONNECTION DIAGRAMS

8-Pin Plastic Mini-DIP (N) Packages



8-Pin SOIC (R) Package



NC = NO CONNECT

PRODUCT DESCRIPTION

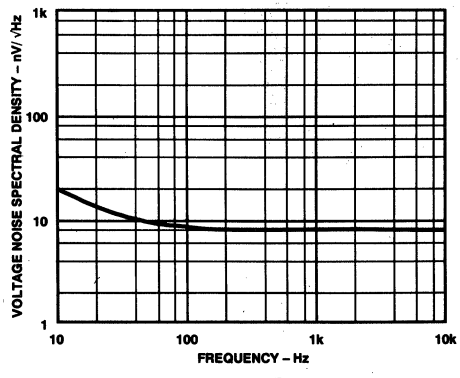
The AD795 is a low noise, precision, FET input operational amplifier. It offers both the low voltage noise and low offset drift of a bipolar input op amp and the very low bias current of a FET-input device. The 10^{14} Ω common-mode impedance insures that input bias current is essentially independent of common-mode voltage and supply voltage variations.

The AD795 has both excellent dc performance and a guaranteed and tested maximum input voltage noise. It features 1 pA maximum input bias current and 250 μV maximum offset voltage, along with low supply current of 1.5 mA max.

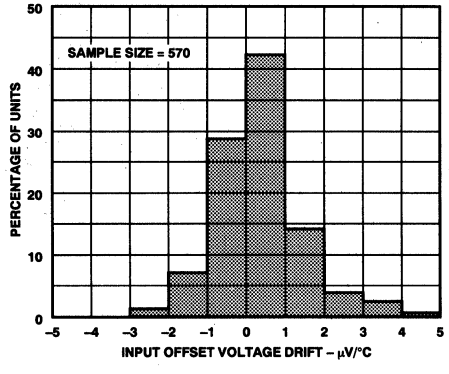
Furthermore, the AD795 features a guaranteed low input noise of 2.5 μV p-p (0.1 Hz to 10 Hz) and a 11 nV/√Hz max noise level at 10 kHz. The AD795 has a fully specified and tested input offset voltage drift of only 3 μV/°C max.

The AD795 is useful for many high input impedance, low noise applications. The AD795J and AD795K are rated over the commercial temperature range of 0°C to +70°C.

The AD795 is available in 8-pin plastic mini-DIP and 8-pin surface mount (SOIC) packages.



AD795 Voltage Noise Spectral Density



Typical Distribution of Average Input Offset Voltage Drift

SPECIFICATIONS (@ +25°C and ±15 V dc, unless otherwise noted)

Parameter	Conditions	AD795JN/JR Min	AD795JN/JR Typ	AD795JN/JR Max	AD795K Min	AD795K Typ	AD795K Max	Units
INPUT OFFSET VOLTAGE[1]								
Initial Offset			100	500		50	250	μV
Offset	T_{MIN}–T_{MAX}		300	1000		100	400	μV
vs. Temperature			3	10		1	3	μV/°C
vs. Supply (PSRR)		86	110		90	110		dB
vs. Supply (PSRR)	T_{MIN}–T_{MAX}	84	100		87	100		dB
INPUT BIAS CURRENT[2]								
Either Input	V_{CM} = 0 V		1	2/3		1	1	pA
Either Input @ T_{MAX} =	V_{CM} = 0 V		23			23		pA
Either Input	V_{CM} = +10 V		1			1		pA
Offset Current	V_{CM} = 0 V		0.1	1.0		0.1	0.5	pA
Offset Current @ T_{MAX} =	V_{CM} = 0 V		2			2		pA
OPEN-LOOP GAIN	V_O = ±10 V							
	R_{LOAD} ≥ 10 kΩ	110	120		110	120		dB
	R_{LOAD} ≥ 10 kΩ	100	108		100	108		dB
INPUT VOLTAGE NOISE	0.1 Hz to 10 Hz		1.0	3.3		1.0	2.5	μV p-p
	f = 10 Hz		20	50		20	40	nV/$\sqrt{Hz}$
	f = 100 Hz		12	40		12	30	nV/$\sqrt{Hz}$
	f = 1 kHz		11	17		11	15	nV/$\sqrt{Hz}$
	f = 10 kHz		9	11		9	11	nV/$\sqrt{Hz}$
INPUT CURRENT NOISE	f = 0.1 Hz to 10 Hz		13			13		fA p-p
	f = 1 kHz		0.6			0.6		fA/$\sqrt{Hz}$
FREQUENCY RESPONSE								
Unity Gain, Small Signal	G = −1		1.6			1.6		MHz
Full Power Response	V_O = 20 V p-p							
	R_{LOAD} = 2 kΩ		16			16		kHz
Slew Rate, Unity Gain	V_{OUT} = 20 V p-p							
	R_{LOAD} = 2 kΩ		1			1		V/μs
SETTLING TIME[3]								
To 0.1%	10 V Step		10			10		μs
To 0.01%	10 V Step		11			11		μs
Overload Recovery[4]	50% Overdrive		2			2		μs
Total Harmonic	f = 1 kHz							
Distortion	R1 ≥ 10 kΩ							
	V_O = 3 V rms		−108			−108		dB
INPUT IMPEDANCE								
Differential	V_{DIFF} = ±1 V		10^{12}‖2			10^{12}‖2		Ω‖pF
Common Mode			10^{14}‖2.2			10^{14}‖2.2		Ω‖pF
INPUT VOLTAGE RANGE								
Differential[5]			±20			±20		V
Common-Mode Voltage		±10	±11		±10	±11		V
Over Max Operating Temperature		±10			±10			V
Common-Mode Rejection Ratio	V_{CM} = ±10 V	90	110		94	110		dB
	T_{MIN} to T_{MAX}	86	100		90	100		dB
OUTPUT CHARACTERISTICS								
Voltage	R_{LOAD} ≥ 2 kΩ	V_S−4	V_S−2.5		V_S−4	V_S−2.5		V
	T_{MIN}–T_{MAX}	V_S−4			V_S−4			V
Current	V_{OUT} = ±10 V	±5	±10		±5	±10		mA
	Short Circuit		±15			±15		mA
POWER SUPPLY								
Rated Performance			±15			±15		V
Operating Range		±4		±18	±4		±18	V
Quiescent Current			1.3	1.5		1.3	1.5	mA

NOTES
[1]Input offset voltage specifications are guaranteed after 5 minutes of operation at T_A = +25°C.
[2]Bias current specifications are guaranteed maximum at either input after 5 minutes of operation at T_A = +25°C. For higher temperature, the current doubles every 10°C.
[3]Gain = −1, Rl = 10 kΩ.
[4]Defined as the time required for the amplifier's output to return to normal operation after removal of a 50% overload from the amplifier input.
[5]Defined as the maximum continuous voltage between the inputs such that neither input exceeds ±10 V from ground.

All min and max specifications are guaranteed.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

Supply Voltage . . . . . ±18 V
Internal Power Dissipation[2] (@ T_A = +25°C)
SOIC Package . . . . . 500 mW
8-Pin Mini-DIP Package . . . . . 750 mW
Input Voltage . . . . . $\pm V_S$
Output Short Circuit Duration . . . . . Indefinite
Differential Input Voltage . . . . . $+V_S$ and $-V_S$
Storage Temperature Range (N, R) . . . . . −65°C to +125°C
Operating Temperature Range
AD795J/K . . . . . 0°C to +70°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]8-Pin Plastic Mini-DIP Package: θ_{JA} = 100°C/Watt
8-Pin Small Outline Package: θ_{JA} = 155°C/Watt

ESD SUSCEPTIBILITY

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 volts, which readily accumulate on the human body and on test equipment, can discharge without detection. Although the AD795 features proprietary ESD protection circuitry, permanent damage may still occur on these devices if they are subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid any performance degradation or loss of functionality.

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD795JN	0°C to +70°C	N-8
AD795KN	0°C to +70°C	N-8
AD795JR	0°C to +70°C	R-8

*N = Plastic mini-DIP; R = SOIC package. For outline information see Package Information section.
